Preface.

The first era of the „Macrolepidoptera of the World; comprising the palearctic fauna, could yet be completed in the year 1914. It is only to-day that the second large division containing the exotic day-butterflies is coming to a close. On 458 plates the whole day-butterflies of the Indo-Australian, American, and Ethiopian ranges were figured, unless they were dispensable or unavailable.

The present fifth volume which I herewith place before the public, comprehends the *Rhopalocera* and *Grypocera* of the whole of America with a delimitation as has been tried to substantiate on p. 3 (of the Introduction). To those who do not consider this delimitation to be sufficient for faunistic reasons — which doubts are not unjustified — it may be pointed out that, in order to finance such expensive enterprises as was the production of the Macrolepidoptera, practical theoretical considerations have sometimes to yield to practical ones. The restriction of the interest or at least of the collections of many intending purchasers upon especially American forms appeared to the editor to be so far-spread that he thought to owe particular consideration to the nations of that part of the globe promising the greatest number of subscribers for the relative volumes.

This consideration appeared to the author to be the more necessary since just of late the work had been considerably subsidized by America. Beside many letters from Brazil, Argentina, Colombia, and Paraguay to the editor and the authors of the corresponding groups of lepidoptera, that were often mentioned in the text, we are particularly indebted to the United States and Mexico for their active support. Especially Mr. ROBERTO MUELLER and Prof. CARLOS HOFFMANN in Mexico (City), Mr. W. SCHAU and H. G. DYAR in Washington, by their unselfish collaboration enabled us to fill up a great number of hitherto prevailing gaps and to eliminate former errors. By the kindness of some more eminent specialists of the American fauna, such as BARNES, BENJAMIN, BOLL, SNYDER etc. — whose names had been gratefully noted already in the first part of the work — we were able to supply figures of specimens which would have never been possible but for the kind control of the owners of such rarities or even unique specimens.

The mentioning of the names of all who assisted the editor in his gigantic work both by word and deed is probably neither intended by them nor is it to the interest of the work; but we consider it to be our duty to express at this place our sincere thanks for their endeavours.

The immense material to which we had to seek access for the sake of elaborating most satisfactorily the American lepidoptera was only partly available on the European Continent. The faunae of Canada and of the United States were the most represented in European, particularly German, Museums. This is especially the place where the above-mentioned assistance of the entomologists of the United States set in; and besides the literature on the North American fauna is already so copious that by its aid an approximate survey particularly of the American day-butterflies could be obtained. By means of an abundant use of the works of ABBOT and SMITH, SCUDDER, the two EDWARDS, HOLLAND, WRIGHT and others with partly excellent figures, and by the aforesaid kind assistance of North American collectors, we believe to have supplied a compilation sufficient for the short draft to which such an extensive work has to be confined.

As to Mexico, the above-mentioned help of Mr. R. MUELLER and Mr. C. HOFFMANN enabled us to study novelties and rarities about which others would scarcely have informed us. Prof. Dr. M. DRAUDT at Darmstadt, whose collection of Mexican lepidoptera is probably unexcelled in Europe, has on the base of this material personally elaborated the *Lycaenidae* and *Grypocera* and thereby rendered a particularly great service to the exploration of this rather defective field, and he was able to supply nearly all the figures of more than a hundred newly described American day-butterflies.

Central America which, by the renowned „Biologia“ of SALVIN and GODMAN and later on by W. SCHAU's publications, is better known than most of the South American tropical countries, could frequently

be elaborated according to the material of A. H. FASSL and the abundant collection yielded by RIBBE from the Chiriqui having been most kindly made accessible to us by the firm of Dr. STAUDINGER and BANG-HAAS. But with respect to this faunistic region — apart from Costa Rica perhaps — we can state that numerous districts have been insufficiently explored, and already the near future may supply us with a more compendious enlargement of our knowledge.

About Colombia and the districts of the Amazon and its tributaries the collections of A. H. FASSL give us ample information. Some plates, such as the *Agrias* on pl. 113 B, have almost entirely been made according to novelties from FASSL's Collection, which he collected in the unhealthy forests of Tropical South America and which cost him his life, for he recently succumbed to the pernicious climate. We feel particularly pleased that he left a permanent memorial in the Additions just to this fifth volume.

From Brazil and the western part of South America there existed likewise rich collections. CARLEPP's plentiful returns from Peru supplied particularly abundant material. In Bolivia it was likewise FASSL who collected very thoroughly though not very long and who put his rich material at our disposal. For the adjacent parts of Argentina, the returns by JOSÉ STEINBACH yielded many good objects, whilst to the south of that country and in Uruguay the editor himself was able to make many observations. The same is the case with Brazil, where the editor collected considerable material especially in Bahia and from where the greatest part of the biological notes originate which were interspersed in the text. Of great value were the consignments from these South American districts by Mr. ZIKAN and Mr. ARP in Brazil.

Moreover, both the compilers and the editor, for the sake of their studies, endeavoured to make use of the special collections as well as of the large Museums. We here once more beg to express our gratitude also to their directors or owners, as far as this had not already been done in the preface to the volumes of the first part. By their kindness COURVOISIER's Collection of the Lycaenids could be viewed, and Mr. ABEL in Leipzig had the kindness to send us some of his Hesperids for comparison. If I mention here that for instance LORD ROTHSCHILD allowed me to study 2500 Erycinids of the Tring Museum, it is easily understood of what great importance such aid was in composing the different chapters.

If the conclusion of this volume has been delayed for an entire decade, nobody will wonder at it who remembers that just the native land of the work was the centre of those terrible convulsions to which the world was exposed during that period. It is, on the contrary, astonishing and above all due to the subscribers' forbearance that a scientific work such as the present one was able to outlast all these heavy blows without being harmed otherwise.

I cannot edit this volume without emphatically thanking the compilers of the different lepidopteral families as well as the publisher for the immense sacrifice which the continuation of this work required just in such hard times. It was the latter's ardent desire to reward, in close collaboration with the editor, the subscribers' great patience to which they had been exposed by the disastrous events of the last ten years, and to reach such a juncture, when the volume of the American day-butterflies could be put before the public and those of the Indian and African faunae are on the point of being concluded.

As to the way how the work was compiled, we may refer to the prefaces of the volumes of the palaearctic part. Nothing has changed in the editor's position towards the so-called international nomenclatural rules. They must be rejected in the zoological world as a universally decisive code of laws, and entomology is not entitled to have an exclusive position therein. This, however, does not preclude that the greatest part of these rules, particularly those representing merely a precise wording of customs used long ago and having nowhere been refused, are useful and have therefore also been applied throughout the „Macrolepidoptera“. They have probably only been rejected as a decisive code in as much as they did not only accomplish their main object of creating a nomenclatural stability, but even often upset it, since constant unearthings and fresh interpretations of old names produced new conflicts with the whole literature on this subject. As our work is intended to be only a manual, we have tried to guard it against this defect which is mostly due to the principle of priority having been too rigidly interpreted, but otherwise we in no way restrained the author in applying the customary nomenclatural laws.

It seems that many entomologists thought the „Macrolepidoptera“ to offer the chance of putting the treatment of lepidopterology on a scientific basis. The editor, however, could not chime in with this view for ideal and practical reasons. Every specialist usually considers those methods and maxims by means of which he gained his most important results to be the most valuable to science. It appears, however, to be impossible to attain in this way the uniformity of the total work aspired at by the editor. Nearly every chapter

would then have been subject to another principle of the mode of compilation. And besides every revolution must be substantiated, and thereby the extensive program of the work would have been rendered disharmonious, unhandy, and its contents would not have been enduring, but at any rate rather antipathetic to most of those using it, 95 percent of whom are no learned specialists. The editor therefore tried to prevent the authors from specialistic digressions however valuable they might be in monographies.

In the 5th volume, like in the volumes of the preceding part, a cursory inspection already shows that the text is chiefly thought to be a complement to the plates. Beside biological remarks it mostly contains hints to more subtle marks of distinction from closely allied species. Wherever the species were easily recognizable from the figures without any danger of errors, as in especially variegated and conspicuously marked genera (*Perisama*, *Catagramma*, *Anaea*, etc.), the text could be confined to but few words on synonymy and patria; on the contrary, certain complicatedly marked Lycaenids or Hesperids often necessitated a somewhat minute description. At any rate the latter has been possible without exceeding very much the number of 1000 pages and 200 plates being the maximum number for the handiness of a volume.

In the text on the whole 15 000 names were explained and illustrated by about 9000 figures on the plates. No sensible man will demand or only expect all the figures to be faultless or even works of art. If, however, the later plates of this volume should exhibit more defects than the first, this is due to the immense difficulties due to the war and revolution.

But we beg the readers to make allowance also for that part of the volume that appeared before the war, just as the reviewers had done for the first part. First and foremost the work is to serve as an orientation, for the quick recognition and estimation of materials, returns from explorations, collections, centuria, single specimens captured etc. For this purpose the figures must be well recognizable and life-like, but they need not be highly artistic. In those cases where copies were only to be obtained from old, technically incomplete works, we have therefore not expressly refused the responsibility for the correctness of our figure. Those who know the old works — and for monographies on single groups only such works will be taken into account — will at first sight find out which figures were made according to HEWITSON, CRAMER, or HÜBNER, so that it appeared to be superfluous to supply long lists about the origin of each original or copy.

We only remark in general that nearly all the figures of the *Papilio* and *Erycinidae* were made according to specimens of the Tring Museum, the *Pieridae* and many *Nymphalidae* according to those from J. RÖBER's collection at Dresden, the *Morphidae*, *Brassolidae*, *Prepona*, *Ageronia* all from the Coll. FRUHSTORFER, the Lycaenids according to those of the collections of FASSL, STAUDINGER-BANG-HAAS, and of the editor. The Mexican forms are mostly copies by Dr. DRAUDT, whilst many Satyrids originate from the collections of STAUDINGER and WEYMER, now in Berlin.

Of particular importance I consider to be the statement that a great many Hesperid figures were taken from the work by CARL PLÖTZ. Though this work, a great part of which is at present in the editor's possession (until its sale), has never been published in the volumes containing the plates (of which there exist about 20), yet, without the inspection of these plates, the numerous publications edited by PLÖTZ cannot possibly be correctly determined. We therefore had some hundreds of the species — mostly Hesperids — appearing to us to be doubtful copied from the 5th, 9th, and 13th volumes, and by the comparison of these original figures it has been possible to remove many an error and doubt from science. Although PLÖTZ' work was never for sale in the book-trade, yet at least part of it has been available to nearly all the active lepidopterologists; HEWITSON, GODMAN, MABILLE etc. have frequently referred to this work. Many figures, particularly those of the Hesperids on more than 1500 plates (the 6 volumes of part XX), have been copied and published by SWINHOE, MABILLE etc. Thus we have also cited PLÖTZ' work as an indispensable text-book and not newly denominated those species that are at once recognizable from the unique figures, but taken them over as sufficiently marked and distributed by copies.

As to the t e x t - v o l u m e we must remark that the editor is only responsible for the German edition. He had no influence upon the two other editions. The French edition, as far as it has been published after 1914, is at any rate entirely unknown to me; I have never seen a single copy. A real completeness could of course only be aspired until the time when the destructive effect of the World's War had not yet interrupted the scientific connexion amongst the nations. The further completion must be reserved to the supplementary numbers and to the time when the torn threads of scientific intercourse amongst the nations will be reknitted.

Unfortunately we could neither in this volume avoid annoying differences between the denominations in the text and on the plates. Technical reasons prevent us from starting simultaneously the description and illustration often based on the same specimen, and thus it was sometimes only after the accomplishment of

the plates that the figured specimens proved to deserve better another, mostly new name which could yet be done in the text, whilst the plates had already been published. We therefore beg to accept this drawback as the consequence of the continuous progress of our knowledge.

Thus the fifth volume, like its predecessors, is sent forth with the sole task of serving as a text-book to all the representatives and friends of lepidopterology. Just as little as the author intended with the volumes of the first part, he strived to create a sumptuous work with as many surprises as possible, with improved systems and unexpected novelties. A systematically and uniformly arranged elaboration of the American day-butterflies, organized into a complete set, with a short description of the habits and stages of development, but with as much consideration of the variations, faunae and synonymy as possible, that is the main task of the work, and if it should be recognized from its contents with how great a devotedness the authors as well as the editor and publisher have bestowed their fullest attention to this design, this acknowledgment will be their best reward.

Darmstadt, May 1924.

Dr. Adalbert Seitz.

===== VOLUME V: =====

THE MACROLEPIDOPTERA
of the
AMERICAN FAUNISTIC REGION

All rights reserved.

Introduction.

The giant continent of America, which extends from the eternal snows of the arctic polar region further south than any other continent, is better adapted than any other to the production of an inexhaustible wealth of the most varied animal forms. Open almost everywhere to the moisture-laden east winds from the Atlantic, it admits the fertilising rains far into the interior, and thus develops an extensive and finely branched network of watercourses, which, in conjunction with the varying conditions of climate and warmth in the successive zones, call into being a fauna of quite unique variety.

Originating from the circumpolar arctic fauna, the entire fauna from southern Canada to Texas acquires a character approaching that of Europe and central Asia. Not only that the dominant animal forms in temperate North America belong, for the most part, to groups which also play a principal rôle in the temperate zone of the Old World, the geographical distribution shows also here the most striking analogies. Among the Lepidoptera, *Argynnis*, *Melitaea*, *Vanessa*, *Apatura*, Arctiids and Catocalas figure prominently in both, and as a single outstanding difference, the preponderance of the Hesperids in America, as against the prevalence of Satyrids in the Old World, is manifest even on superficial consideration. But the sum total of the forms to be observed in the northern temperate zone is almost equal in both hemispheres, while one half of the eastern temperate lands — corresponding roughly to the whole of the western — contains about the same number of Lepidoptera as that, namely about 6500 forms.

This is changed as soon as we reach the tropical zone in America. Quite suddenly all resemblance to the fauna of the Old World vanishes. The singular and highly characteristic *Morpho*, *Ithomia*, *Melinæa* and *Heliconius*, *Castnia* and *Glaucopis*, *Pericopis* and *Cyrtopoda*, the wonderful forms of neotropical Erycinids the tailed Hesperids, etc., have no counterparts in the Old World. They give to the South American fauna such a distinct individuality, even compared with that of the cooler parts of North America (north of Mexico), that the lepidopterous fauna of South America may well be designated the most characteristic of the world. What its principal peculiarities are, has already been pointed out in the introduction to this work, and will be further considered below.

That in spite of all this we have decided not to separate the North from the South American fauna, as has hitherto been done in zoogeography, under the terms Neotropical and Nearctic, is due to the fact that a basis for any sharp delimitation is wanting here, as it is between the Indian and Australian faunistic regions. Just as the limits there drawn by WALLACE are arbitrary, so also in America the otherwise applicable principle of faunistic division fails us. Let us, for example, compare the conditions in America with those of the much more compact continent of Africa: south of the Sahara there is no species of *Euchloë*, no *Aporia*, no *Procris*, no true *Zygæna*, no *Vanessa*, no *Pararge*, no *Ocnogyna*, in short all the species are absent which in North Africa are the commonest, not to say the most obtrusive representatives of the butterfly world. On the other hand the north has no *Euphaedra*, no *Cymothoe* or *Euryphene*, all the groups of *Papilio* and Pierids which are distributed throughout the rest of Africa are wanting, we seek in vain for *Amazilia*, which is so characteristic of the whole of tropical Africa, and so on.

In America there is no such insuperable barrier as is formed by the great Sahara desert of Africa, with its absence of vegetation. Thus we find the otherwise purely South American Neotropids pushing northwards into California, the genus *Heliconius* into Florida, while *Argynnis*, *Colias*, *Catocala*, etc., extend their range southwards on the heights of the Andes; in a word, the two faunas so encroach upon one another that we prefer to draw no boundary at all rather than an artificial one; and we do this so much the more willingly because these theoretical considerations fit in with a series of practical ones.

Among the characteristics of the lepidopterous fauna of America, which are most prominent in South America, we would mention its **richness in species**. It used to be said that the double continent of America alone contained about as many species as all the rest of the world. This comparison was applicable so long as we had not learned to distinguish all the numerous local forms of certain Malayan

and Indo-Chinese butterflies, which result in the appearance of a single species, on all those larger and smaller islands of the Malay Archipelago, in a dress similar, yet with constant differences according to the locality. But since the species of the Old World have been split up into such a large number of races or local varieties, or subspecies, rainy- and dry-season forms, mountain forms and those of the lowlands, the more compact South America, being for the most part more regularly tempered, without pronounced rainy season, has lost very much of its preeminence.

Now when one takes into consideration that any butterfly, of whatever species, would be able to fly from Canada as far as to Cape Horn without meeting with any direct, insurmountable obstacle — neither such a sharply defined desert as separates Northern from Central and Southern Africa, nor a sea, as between Australia and India — it is not easy to understand how it is that we find Castnias, Neotropids, Hesperids or Catagrammas in almost every district of America in distinct forms, mostly unconnected with one another by transitions. In this is manifest a creative energy of unusual richness, such as occurs in no other country to the same extent.

The **lavish endowment** of its species with brilliant and conspicuous colours is the second principal characteristic of the American fauna. In India and tropical Africa there are also plenty of gay species, which fact we do not leave out of account; but while the Old World everywhere produces, side by side with the gay and richly ornamented forms, multitudes of others which are tawny, white or neutral brown in colour, many of the open places in the South American woods are alive with the little gold- and silver-marked Syntomids or the azure blue giant butterflies. None of the Old World species can vie with *Argopteron aureipennis* in its pure golden under surface, or show such rich adornment of silver as *Dione moneta*, or such brilliant blue ground colour as *Morpho cypris*. And even those colours which have not the metallic or silky gloss are nevertheless extremely elegant and pleasing in their arrangement. Very frequently they consist of bright red, orange or blue-green bands or longitudinal spots on a deep black ground, resulting in more quiet richness and fulness of colour than a stiffer, more overloaded scheme of markings. Such crude contrasts of colour as occur in the *Papilio agamemnon* group, in *Neurosigma* and in *Catphissus*, are rare in America. A deeply coloured, though almost always only unicolorous band suffices to make *Epicalia*, *Chlorippe* and *Prepona*, *Callicore* and *Adelpha* the most beautiful forms which a refined taste could imagine.

The phenomenon of mimicry, which was fully discussed in the introduction to the first part of this work, appears in America in an altogether special and characteristically modified manner. There are many localities in South America, often quite circumscribed in extent, in which almost all the lepidopterous species that occur in any numbers have one and the same wing-pattern indifferently, whether they be butterflies or moths, whether stoutly-built Swallowtails or weak Pierids or shy Nymphalids. In Colombia one may see flying about a single flowering shrub a number of butterflies all coloured and marked alike, but belonging to four entirely different groups. They are all black with an oblique scarlet band on the forewings. The first is a Pierid (*Perceute leucodrosyne*), the second a Heliconius (*Heliconius melpomene*), the third a Swallowtail (*Papilio euterpius*) and the fourth (*Adelpha isis*) a species of Nymphalid allied to *Limenitis*. In certain districts of Southern Brazil a yellow band on the forewing and dentated longitudinal stripes on a brownish yellow ground provide the general scheme, which is followed by Pierids (*Perhybris*, *Dismorphia*), Danaids (*Lycorca*), Heliconians (*Heliconius narcaea*) and even some moths (*Chetone*). I have elsewhere spoken of a tendency of certain districts to produce uniformity in their inhabitants, and although kindred phenomena are not wanting in India, or particularly in Africa, they are far less conspicuous there than in America.

Just as the present mammalian fauna of South America is wanting in gigantic forms, so too its Lepidoptera are for the most part of only medium size. Only in *Caligo*, *Morpho*, some Sphingids and the giant Noctuid *Thysania agrippina* do we find great dimensions attained; there are no actual parallels to the huge *Attacus*, or to *Ornithoptera* with its great uncouth females. And as in size, so also in shape there is not the same tendency towards grotesque, unintelligible forms as one is struck by in many genera of the Old World, such as *Leptocircus*, *Sericinus*, *Drurya antimachus*, etc. Beyond the development of tails in normally untailed families (*Nymphalidae*, *Erycinidae*, *Hesperiidae*) there is little that is very strange in the aspect of the American Lepidoptera.

In addition to these peculiarities of the American fauna, there are some others which are not so difficult to explain. In a large number of districts, especially in South America, there are no regular wet and dry seasons. In the neighbourhood of Rio de Janeiro sudden changes are possible on almost any day of the year, and the rainless periods are variable both in their duration and in the time of their arrival. Thus the conditions there — as we have already briefly mentioned — do not lend themselves in the same pronounced way to the development of **seasonal dimorphism** as in many localities of the Old World, where the conditions of weather are perfectly regular, the rains and the heat of the sun being confined to certain months.

Polymorphism also does not seem, in another respect, to be developed to the same degree as in the Old World; namely, in its local conditions. Although in *Papilio lysithous*, for example, we observe the same conditions which obtain in many Indian species, namely that in different districts it mimics the different

Aristolochia-Papilios which occur there — e. g. in South Brazil as *P. pomponius*, mimicking *P. perrebus*, in Rio de Janeiro in the form *lysithous*, copying *P. agavus* — yet without doubt such cases are wanting in America as that of the Indian *P. menmon*, in which some 30 different forms of female belong to one almost constant male form.

The strict **localisation** of Lepidoptera in America is easily explained by the peculiarities of the conditions of vegetation. Like the Old World steppes, the prairies of North America and the Pampas of South America are not adapted to produce a great abundance of forms or even a moderate number of showy and elegant species. Hence we find *Morpho*, the larger Nymphalids, *Castaia*, etc., disappear rather suddenly from the district as soon as we leave the great Southern and Central American forest region. Hence, also, the West Indies, which are either poor in forests or altogether devoid of them, are far behind the neighbouring mainland in respect of their lepidopterous fauna, while conversely the East Indian Archipelago is especially rich in species.

It greatly surprises those who visit different parts of the American continent to notice the great **resemblance between northern and southern districts** which are separated by vast tracts of land differing entirely from both. The Argentine pampas produce species altogether analogous to those of the United States, often even the same species, while they are absent from the whole of the Neotropical forest region which intervenes. Almost at the same latitude where the last *Morpho* leaves us, whether northward or southward, we find *Colias*, *Pyrameis carye* and *Deiopeia* flying. *Euploia claudia* occurs both in the United States and in Uruguay in hardly distinguishable forms, while in the intervening tropical South America it is entirely absent, being supplanted by the very different *Eupt. hegesia*. Nothing analogous is known in the Eastern Hemisphere: the numerous Acraeas of South Africa vanish in the tropical zone and do not reappear north of the Sahara; *Argynnis*, which in America appears again in Chili and Argentina after missing the tropics, vanishes finally in the East on reaching the tropical region; neither South Africa nor Australia possesses any species of the Nymphalid group, which is so plentifully represented in the North. On the contrary the well-represented *Precis*, *Amauris*, etc., of South Africa do not reappear in North Africa or in Europe, and of other characteristic genera of the Old World, such as *Teracolus* and *Charaxes*, scarcely one species in a hundred extends from one temperate zone across the tropics to the other.

The rôle which the individual families play in the American fauna will be easily seen from the special part; attention need only be called here to a few points which result from a comparison of the fauna of the New World with that of the Old.

The **Papilios** of temperate North America surpass those of the corresponding latitudes of the Old World. San Francisco, St. Louis or Washington has two or three times as many species of *Papilio* as Spain, Algiers or Asia Minor, while on the other hand *Parnassius*, rich as it is in forms in the Old World, has only a few somewhat scattered, subordinate forms in the New.

The **Pierids** are pretty equally represented on both sides of the Atlantic, especially since some have been transplanted during the last century.

The **Danaids** show an extremely close parallelism. With only a single species crossing the 40th degree of N. latitude, their number so increases in the tropics as to become dominant, and the number of very closely related forms would be almost equally the same in the Western Hemisphere as in the Eastern if we reckoned the Neotropids, about to be mentioned.

But the **Satyrids** are considerably less prominent in the temperate zone of the New World than in that of the Old. In the tropics, where the Satyrids wane and tend to give place to other groups, the contrast becomes less.

Preeminent among American forms are the **Ithomiidae**, related to Danaids, and which have been designated Neotropids, from their characteristic occurrence in the Neotropical region. Even the earliest naturalists who made any adequate observations in South America, such as BATES and WALLACE, were astonished at the enormous number of individuals, as well as the multitude of species which occurred together in small and circumscribed localities; BATES even wondered how the species, often deceptively similar to one another, managed to find out their right mates for copulation. HAASE, on morphological grounds, compares with this group, so rich in species, the genus *Hamadryas* of the Old World, which is equally poor in forms; from the biological standpoint it is better compared with *Euploea*.

The **Nymphalids**, as one of the most universal groups, occupy a prominent position in both hemispheres. It is hard to say on which continent their preponderance over certain other families of Rhopalocera is the most conspicuous. It is the Nymphalids which include most of the forms that are common to both hemispheres. *Vanessa antiopa*, *Pyrameis cardui* and *atalanta*, *Polygonia c-album*, *Argynnis tricularis*, *freiya*, *frigga*, *chariclea*, etc., connect the American fauna with the eastern and to a certain extent form a bridge.

The **Erycinids** of the Old World do not come anywhere near the wealth and variety of forms to which this family attains in America. To little over 100 species of the Eastern Hemisphere there are above 1000 in the Western, and at the same time the former are comparatively uniform structurally while the latter show manifold differences. America not only produces a number of original forms in this family, but

it is also rich in examples of mimicry, in which Erycinids copy members of the Nymphalids, Ithomiids and even protected Heterocera. Thus *Themone pais* mimics a *Mechanitis*, *Themone poecila* a *Phyciodes*, *Ithomeis* and *Compsotheria* copy Neotropids, *Lypropteryx olivia* resembles in flight a *Calodesma* of quite the same colouring, and the little *Syrmatia*, with their quick, buzzing flight, bear, as they dash past one, more resemblance to flies than to butterflies.

The **Lycaenids** show, in the northern Nearctic region, many forms belonging to the genus *Lycaena* or nearly related thereto; but as one proceeds further south *Thecla*-like forms increase, much as in the Old World. These Neotropical forms greatly exceed in size and brilliance the Indian *Arhopala*.

The most interesting American group is unquestionably the **Hesperids**, which in many South American localities occur in such a wealth of forms and individuals as to surpass, in variety and abundance, all the rest of the Lepidoptera. The long-tongued species appear to be the sole fertilising agents for some plants, and the picture of the white-flowered bushes thickly covered with black *Eantis* abides vividly in the memory of everyone who has collected in South America.

Among the Heterocera the Zygaenids are far less prevalent than the **Syntomids**, which are extremely well represented and often lavishly adorned with metallic colours. Here a wide field is opened for mimicry. The moths which are still commonly designated "Glaucopids" appear in the most wonderful garb, some copying the predacious Hemiptera, others beetles, but the largest number Hymenoptera. The strongest Hymenoptera in the world, the species of *Pepsis*, which wound bird-spiders with their sting and carry them off as food for their offspring, are copied by a very large number of Syntomid species. Under the name of "Marimbondo" this wasp is dreaded in America both by men and animals, on account of its terrible sting, so that in fact no better model could be found for protective resemblance. Entire genera of Syntomids, such as *Macrocneme*, almost exclusively copy these giant wasps.

The **Castniids** present, in some measure, a transition from the moths to the Hesperids. The true Castniids, such as the genera *Castnia*, *Gazera*, etc., are absolutely confined to America and indeed to its tropical and subtropical parts. We see in them moths with entirely the habits of butterflies, which not only feed, like many day-fliers, at flowers which grow in the sun, but also station themselves on points of vantage at the extremities of the foliage where they drive off their enemies, play with their own kind, and lay wait for the passing females.

The **Arctiids** of North America present many similar forms to those of the Old World, several genera and some species, such as *Arctia caja*, *Parasemia plantaginis*, *Phragmatobia fuliginosa*, being common to both hemispheres, without belonging to the holarctic polar fauna. The specifically American forms do not make their appearance in numbers till further south, where they appear of an entirely different build and colour; as *Ecpantheria* and *Halesidota*, which are specially developed in Central America, and the curious *Palustra*, whose larva is aquatic. But although the most singular forms of "tiger-moths" live in the tropics, the gayest and most beautifully marked are found in temperate North America, such as *Apantesis*, *Platyprepia*, *Haploa*, etc.

The **Lithosiids**, which in America, as in the Old World, are represented mostly by small forms, are often, especially in tropical America, brightly coloured and of diurnal habits. In North America itself scarcely 50 forms occur, they seem to reach the height of their development in the warm valleys of the Andes, just as in the East the slopes of the Himalayas have been shown to be particularly favourable to their production. No species are known which are common to both hemispheres; indeed hardly any genera, if we follow HAMPTON (as against KIRBY and DYAR) in removing *Utetheisa* from the family *Lithosiidae*.

The **Liparids** of America, in so far as we accept the present composition of this family, are considerably less prevalent than those of the eastern world. *Ocneria dispar*, the "gypsy-moth", is an introduced species, whereas *Orgyia antiqua*, which is widely distributed in the west of the Old World, and reaches far north, is to be regarded as indigenous. We assume this to be so, although the species is common at some of the European ports (particularly Hamburg) and the larva is fond of spinning up on bales of merchandise, where the sluggish female also lays its eggs, so that every year large numbers are probably dispersed to the four winds. In the genus *Gynaeophora* the Liparids of America possess the species *G. groenlandica* and *rossii*, which reach the farthest north of all the Heterocera -- perhaps of all Lepidoptera.

The **Limacodids**, a family of universal distribution, are very plentifully represented in South and Central America, and develop elegantly marked, though small forms, many of them with a silky or metallic gloss on the wings. From temperate America about 50 forms are known, which is about $\frac{1}{10}$ of the total of known species. From the whole of America perhaps three times as many are known, or over $\frac{1}{3}$ of the total of known forms. It is remarkable that the northern part of America produces a far larger number of forms than that of the Palaearctic Region, which in many districts is very poor in Limacodids; thus in the whole of Europe only two species occur, i. e. less than $\frac{1}{2}$ per cent. of the known species.

The **Psychids** as still constituted at present, do not form a homogeneous family. The case-making of the larvae and the degeneracy of the female are due to convergence, though they have repeatedly been taken to indicate relationship. In America the Psychids play only a small rôle; only 15 per cent. of the

200 known forms inhabit the western continent, and only about a dozen of these occur in temperate North America.

It might appear singular that a family whose females are each and all immovable should have such an enormous range as the Psychids, which are represented in the remotest islands, such as New Zealand, Teneriffe, etc., and often by characteristic species. But it must not be forgotten that their larvae are extremely active and endowed with great powers of resistance, and many, if not all the species are parthenogenetic, i. e. capable of propagating without previous copulation. Nothing would be more erroneous than to infer the existence of a submerged continent from the occurrence of the Psychids on both coasts of the Atlantic. Their transplantation from America to the Old World and vice versa could very easily be effected by drift-wood. I have fished out from the Plata River floating boughs on which a number of cases of *Oiketicus platensis* were spun up, some containing sound larvae, others living pupae. It appears that the larva is capable of making its case watertight. I found large Psychid cases on the coast of North-Shore in the harbour of Sydney, Australia, which were spun up on the rocks, and over which every wave washed at flood-tide; they contained uninjured larvae. Thus their transplantation by means of drift-wood is not at all improbable; indeed they are not even threatened by many special dangers for their long and troublesome voyage. Psychid larvae can fast for a very long time, and when this is no longer possible to them, any food is accepted. The larvae of *Amicta febricta*, which I took in numbers in North Africa from a dry desert-plant, were fed up to the pupal stage in Europe on pear-peel; and inasmuch as a single female Psychid is sufficient to increase the range of a species, the greater wonder is that no species of this family is cosmopolitan, indeed that there is none which is possessed by America in common with the Palaearctic fauna.

The **Lasiocampids** as a whole are not yet sufficiently well known to allow of our forming a definite judgment as to their distribution. Without doubt America has over one-third of the 800—1000 existing forms. With the very large number of species which are already known from South America, it must be assumed that a more thorough exploration of the interior of Brazil will bring to light many more. As at present constituted, the group is not even homogeneous, so that many alterations are to be expected when the Neotropical forms, in particular, are fully worked out. As the family is now constituted, America possesses numerous exceptionally interesting forms. The larvae of the genus *Megalopyge*, remarkable for their peculiar tufts of hairs, are dreaded in America on account of the inflammation which these hairs cause. In one lady who came under my treatment they had produced swellings on the arm and breast, with several days' fever, so that their effects even exceed in intensity those of the hairs of *Thaumatopeoa*. Sometimes there is an unusually pronounced sexual dimorphism in this family, as in *Heliconisa pagenstecheri*, whose female was long known as *Dirphia costora*. In the New World, as in the Old, some of the Lasiocampids are of economic importance.

The **Saturnids**, of which there are somewhat over 400 species in all, are almost equally divided between the New World and the Old. In this magnificent group the relative richness of America is shown by its attaining, in the number of its Saturnids, to a total equalling those of the great continents of Asia and Africa combined. Against six for the whole of Europe, some 40 forms inhabit temperate North America. The Ceratocampids, too, which are related to the Saturnids, and of which there are about 50 forms, belong to America alone; whilst the Brahmaeids of the east possess hardly more than a dozen forms. On the other hand America is somewhat behind the Old World in respect of the true Bombycids.

The American **Sphingids**, in comparison with those of the Old World, show a proportion of 3 : 5, 370 out of about 1000 known forms occurring in the New World. The exhaustive work of ROTHSCHILD and JORDAN has thrown a very full light on the distribution of this family. America is particularly rich in gigantic hawk-moths, such as *Pachylia*, *Cocytius*, *Pholus*, *Pseudosphinx*, etc. One would expect, from the extensive powers of flight of most Sphingids, that quite a number of representatives of this group would be common to both hemispheres, which, however, is not the case; only quite a few species, such as *Celerio lineata* and *gallii*, appear in both without any very material differences.

In the **Notodontids** we have another heterogeneous group, in the composition of which alterations will certainly be made — at least by its splitting up into several groups — when it is worked out morphologically with a regard for the finer anatomical details.*) It is therefore of little value to fix the number which belong to the Western Hemisphere, out of the 600 odd species at present placed in the Notodontids. They form by far the greater part; the genera *Rosema*, with grass-green forewings, *Nystalea*, with its noctuid habits, the North American *Datana*, *Heterocampa*, etc., are rich in species which play an important part in the western continent on account of their richness in individuals.

In the **Noctuids**, conditions are much the same as in the Old World, especially as described in dealing with the Palaearctic Noctuids (vol. III, p. 11): in the south more diurnal species, in the north duller coloured genera (*Mamestra*, *Acronicta*, *Agrotis*, *Hadenia*, etc.) which sleep by day; but in the north, in addition, a wide distribution of the Catocalids, lightly sleeping night-fliers which are specially adapted for

*) AS PACKARD has done for the North American species.

their resting posture, but have preserved their bright colour on the underside as well as on the hindwing, which is concealed beneath the grey forewing. In the tropics of America the Noctuids recede in point of numbers, as only a few groups, such as *Hyblaea*, *Laphygma*, *Prodenia*, etc., appear in large number at times; however, the western tropical species frequently develop gigantic forms, such as *Erebus* and before all *Thysania agrippina*, which has the largest expanse of wings of all the known Lepidoptera.

The **Geometrids** show a very uniform distribution throughout the world. Their relatively weak flight makes them insecure on islands, and is a hindrance and menace to their propagation in the smaller storm-beaten islets. This general rule holds also for America, and so does the other rule, that the generally duller and darker colours of the temperate climate give place to brighter and often beautifully marked colouring in the warmer regions. As many species extend far northwards, there is a possibility of communication between the two hemispheres in respect of their Geometrid fauna; and although there are far fewer Geometrids than Noctuids common to the two, yet several species, such as *Eugonia magnaria (alniaria)*, *Hydria undulata*, *Anagoga pulveraria*, etc., occur in both without any essential differences.

Among the larger Geometrids, the genera *Azelina*, *Clysia*, *Oxydia*, *Prochoerodes* and *Sabulodes* are particularly prominent in America. In their habitus they borrow a good deal from the forms of other groups which inhabit the same region, but without showing any mimetic tendency. As in the Eastern Hemisphere, metallic colours are only developed exceptionally in the American Geometrids (*Ophthalmophora*); on the other hand we are confronted with true American schemes of colour and markings in the brightly coloured bands on a black ground which occur in *Scordylia*, *Nelo*, *Sangala*, etc.

The above is in broad outline a comparative picture of the American fauna and that of the Old World. It ought to be mentioned that some groups, such as the *Cymbidae*, are not represented at all in America; others, such as the Nyctemerids, only by a few forms, which might probably be better referred to some other group. It is very strange that the nearest representative of the tropical American genus *Urania* belongs to South-East Africa; cases like this belong to the at present still very numerous geographical puzzles.

BUTTERFLIES

All rights reserved.

Diurna, Butterflies.

With the exception of the Neotropical Brassolids, all the American butterflies are day-loving insects. Even the dark-coloured Satyrid genera and the colourless *Haetera* and *Ithomia* fly by day, though in the dusky shade of the woods. What was said in the Introduction as to the colouring and the scheme of marking of the Lepidoptera of the New World, is applicable in a special degree to the colours of the frequently gorgeous butterfly-wings. In spite of the very considerable abundance of true Rhopalocera, they do not in America preponderate over the second group of Diurna, the Grypocera, to such an extent as in the Old World.

A. Rhopalocera, true Butterflies.

The differences from the Grypocera are given in vol. I, p. 7. The distribution of the Rhopalocera in America extends from Greenland to Cape Horn. In the islands lying to the south of this there do not appear to be any butterflies. These attain in the American genus *Morpho*, allied to the Satyrids, a high degree of development; among the Nymphalids we find in *Agrias* evidently modern forms, and among the Ithomiids the most pronounced examples of Mimicry.

Division I: Papilionina.

The Papilionina do not in America attain the same dimensions as in the Old World, for example in the Indo-Australian *Ornithoptera*. The largest American Papilionid is *Pap. homerus*, an island species. The genus *Parnassius*, rather prominent in the north of the Eastern Hemisphere, is much less so in America. The Pierids are similar to those of the Old World in their habits, and extend, like these, far into the north polar region. (SEITZ.)

Family I: Papilionidae, Swallowtails.

Palpi short, lying close to the head, occasionally long and projecting (*Teinopalpus*, North-India). Antennae of three types according to the structure of the segments: the fine sensory hairs beneath and laterally almost equally distributed over the proximal part of each segment, or there is a cavity on each side covered with sensory hairs (reminding one of the Nymphalids), or there is only one row of such cavities present (reminding one of the Pierids); the upperside scaled or naked. Mesothorax very strongly built, the sternum completely fused with the episternum, the suture (as in the Pierids) outwardly quite wanting. Fore legs fully developed; fore tibia with spur on the underside; claw simple, very rarely cleft as in the Pierids*); paronychium and pulvillus wanting. Cell of both wings closed; in the forewing the second discocellular (between the 1. and 2. radial) the longest, the 2. radial arising from the lower angle of the cell, the 3. discocellular standing in or almost in the prolongation of the median, hence four veins arising from the hindside of the cell, upper submedian vein often present as a short transverse vein arising from the median near the base, 3. submedian vein short, free, running into the hindmargin; hindwing with pre-costal vein, and one submedian vein. — Egg round or flattened, without prominent sculpturing. — Larva before the first moult with rows of bristle-bearing tubercles, which in the later stages disappear, or are

*) In one species of *Leptocircus*.

replaced by fleshy processes or hard spines; on the neck a fleshy, reversible fork of a red or yellow colour, secreting a scent, and being stretched out in defence (the osmaterium); lives free, but some species bend down the edge of a leaf so that a sort of tunnel is formed in which the larva conceals itself; some larvae are gregarious. — Pupa fastened at the anal extremity and by a thread encircling the thorax and wing-cases, or lying in a loose cocoon on the earth or just under its surface; three moveable abdominal segments.

The family is cosmopolitan, but only a few forms cross the polar circle. Except Africa, where the *Aristolochia-Papilios* are wanting (only Madagascar has one species), the tropics are characterised by their richness in that group and the Kite-Swallowtails, whilst the temperate zone of both hemispheres possesses in *Parnassius* a type which is not met with in the true tropics; *Baronia brevicornis*, indigenous to Guerro, West Mexico, is the most southerly form recalling *Parnassius*.

Whilst in the Old World there are quite a number of genera besides the large comprehensive genus *Papilio*, all the American forms belong to only four genera: *Papilio*, *Euryades*, *Parnassius* and *Baronia*.

1. Genus: **Papilio**, Swallowtails.

Forewing always with median spur (1. submedian), at least one of the discocellulars placed longitudinally; hindwing with precostal cell. All the species have the pupa attached by a girth. The so-called genus *Papilio* falls into 3 divisions, which are sharply separated from one another in the larva, pupa and imago. This natural classification was founded by HORSFIELD in 1856, but not recognised by later authors (ERICH HAASE excepted). The forms of the first group, the *Aristolochia-Papilios*, so tenacious of life, have a strong smell, and are often mimicked by species of the other two divisions, and in consequence of this similarity the models and mimics have been erroneously regarded by some authors as closely allied.

A. *Aristolochia-Papilios*.

Antenna without scales, underneath on both sides with a cavity on each segment. The outer ventral row of spines of the tarsi not separated from the dorsal spines by a spineless longitudinal depression. — Larvae on *Aristolochia*, rarely on allied plants; densely covered with very short hairs, velvety, only the head, the prothoracic plate and the legs being shiny; each segment with a belt of fleshy tubercles, which bear hairs, but no strong spines; the anterior tubercles often prolonged. — Dorsum of the pupa incurved, wing-case strongly expanding sideways; on each side of the abdomen dorsally a row of humps or lobes, which often form an almost unbroken ridge. — Tropical insects, represented in North America by 2 species (*P. philenor* and *polydamus*).

The American *Aristolochia-Papilios* are divided into 2 sharply characterised subdivisions.

Section A.

Body with red spots. Cavities of the antenna very distinct; precostal cell distally widened, cell of the hindwing more or less pointed. — Here belong most of the forms. They are almost all woodland species; some are only found in the shade of the forest. The butterflies are taken in open spaces in the woods, on their outskirts, and on the banks of rivers, where they frequent flowers, or imbibe moisture from the damp sand. The ♂♂ are generally good fliers, while the ♀♀ are mostly slow and heavy on the wing. Some species inhabit marshes, others occur only in dry, sandy places in the woods.

Ascanius-Group.

The species of the *ascanius*-group, with which we begin, have a spatulate tail. The two sexes are similar. The ♂ has on the hindwing a hindmarginal fold, covered with white wool.

columbus.

P. columbus H.-Sch. (= *gundlachianus* Fldr.; *grotei* Blake) (1a). The brightest coloured American *Papilio*, which may be recognised by the brilliant blue bands on the forewing. — The dark ash-grey larva is striped longitudinally, the head and thoracic legs are black; the black longitudinal stripes in part margined with white; the anterior and posterior segments bear long pointed tubercles which are partly white. — Flies in Cuba, and occurs not infrequently in the mountainous eastern part of the island, especially near the coast, where it is met with on flowers, and sometimes also drinking at pools.

ascanius.

P. ascanius Cr. (1a). A broad white band traverses both wings; on the hindwing it is more or less red. — The larva is light brown, and bears pointed tubercles on all the segments. The imago, which hitherto has only been observed in the province of Rio de Janeiro, flies in the neighbourhood of Rio over marshes, where it can only be followed with difficulty and often by wading in the water; the species of *Aristolochia* on which the larva feeds only grows in such situations. According to Mr. J. ARR the species is by no means scarce at Rio de Janeiro in these swamps, but only in exceptional cases goes far from them; and it is on account of this inaccessibility of its haunts that good specimens are not common in collections. Larva October to April.

P. agavus *Drury* (1b). The red anal spot of the hindwing very large, Z-shaped. The abbreviated *agavus*, white band of the hindwing is somewhat variable. Although the species is quite common even in gardens in the neighbourhood of Rio, especially in damp, shady places, we are still ignorant of its early stages. The insect frequents flowers, and is easy to catch. — Minas Geraës southwards to Rio Grande do Sul, westwards to Paraguay and the adjoining parts of Argentina: not extending to the foot of the Andes.

P. proneus *Hbn.* (= *phryneus* *Luc.*) (1b). Both wings with narrow white band, the red sub-*proneus*, marginal spots of the hindwing straight or slightly curved: anal spot not V-shaped. — Minas Geraës to Parana; near Rio only in the Organ Mountains.

P. chamissonia. Both wings with white band, that on the hindwing abbreviated: cell-spot of the hindwing not extending further towards the base than to the 2. median; red anal spot V-shaped. — The larva is brownish black, with an oblique white band, extending laterally from the 6. segment to the tubercle on the 7. The pupal stage lasts three weeks. The butterfly is very common and is one of the earliest spring species (August). From August to April there are at least three generations. — **diodorus** *Hoppl.* *diodorus*, (= *campeiro* *Foett.*) (1b) has entirely white fringes. The breadth of the white band is variable. Minas Geraës: in the interior from São Paulo: Goyaz: Bahia. — The form **chamissonia** (= *ascalus* *Godt.*, *chamissonia*, *echedorus* *Boisd.*, *eurydorus* *Luc.*), described by ESCHSCHOLTZ, occurs near Petropolis, in São Paulo, Parana and S. Catharina. Near Rio itself the species is absent. In this form the fringes are partly black, at least at the extremities of the veins. The specimens with a broad white band on the hindwing may be designated as ab. **bunichus** *Hbn.*: these are especially common in São Paulo and in the Organ Mountains. *bunichus*.

P. perrhebus. Wings entirely without bands. The larva lives on *Aristolochia ciliata*, and bears on all its segments tubercles which are partly white and partly yellow: an oblique band on the 6. and 7. segment is yellow. We know two geographical forms of this species. — In Brazil, from São Paulo to Rio Grande do Sul, in Paraguay, and in the neighbouring parts of Argentina, occurs a dark form, in which the head, the palpi, and the submarginal spots on the upper surface of the hindwing are distinctly red; this is **perrhebus** *Boisd.* (1a). — The form from Buenos Aires, the province of Entre Rios, and Uruguay, is **damocrates** *Guen.* It is much paler: the head and palpi are black, and the submarginal spots on the upper surface of the hindwing are not bright red. The species is especially common near rivers. *perrhebus*, *damocrates*.

P. phalaecus *Hew.* (1b). The only *Aristolochia*-Papilio with a spatulate tail which has hitherto been found in tropical America between Costa Rica and Paraguay. The body is very hairy. The white band, which traverses both wings, is intersected by black veins. — Eastern Ecuador. *phalaecus*.

P. photinus *Doubl.* (1d). Upper surface with blue gloss, especially in the ♂. Wings without bands: hindwing with two rows of red spots. — Mexico to Costa Rica: a common species. *photinus*.

P. alopis *Godm. & Salv.* Spots on the hindwing smaller than in *P. photinus*, at least partly white, those of the inner row very small, partially wanting. — West Mexico: Nicaragua. *alopis*.

P. dares *Hew.* (1d). Only one ♀ known, which is in the British Museum (coll. HEWITSON). Tail short; forewing with a small white spot on the disk; hindwing with two rows of red spots, which are larger than in *photinus*. — Nicaragua. *dares*.

P. montezuma *Westw.* (1a). Forewing without band. Hindwing with a row of red submarginal spots. — Mexico to Nicaragua: one of the commonest species. *montezuma*.

Aeneas-Group.

The following forms, which have white marginal spots, we unite as the *aeneas*-group. The species are partly hard to differentiate, especially as the two sexes are often very unlike. Very little is known about the earlier stages. Many of the species inhabit marshy woods, where the larvae live on *Aristolochia*. In consequence of the inaccessibility of these forests, quite a number of forms are still very rare in collections, and there are certainly still some species which have hitherto escaped the net. Scent-organ of the ♂ mostly with white wool, more rarely with black scales.

P. hahneli *Stgr.* (1c). One of the most remarkable of the American *Papilios*, and doubtless the best discovery of the successful collector after whom the species is named. Tailed. Forewing with three yellow-grey bands or patches; hindwing with area of the same colour, occupying the greater part of the wing. — Massauary, near Maués, Amazon River. Collecting in the neighbourhood of the Amazon, from Pará to the foot of the Andes, seems to be more difficult nowadays than formerly. It is true the steamboat takes the collector from place to place, but in the neighbourhood of the larger settlements there is no longer much for him to seek, and living has become extraordinarily expensive. And it is difficult to find a place near the forest fit to live in and secure against flagrant robbery, and the collector is very

dependent upon chance in this respect. — *P. hahneli* has not been again discovered; but so many Amazon species are represented in collections by only a few specimens that it must be assumed that the real haunts of this insect are not yet known.

triopas. **P. triopas.** Forewing with two bands. Hindwing small, recalling the Old World *Troides* (= Ornithoptera). The form from the Lower Amazon and Dutch and French Guiana is the commoner in collections; this is **triopas** *Godt.* (1c). — The form from British Guiana, which is called **mithras** *Grose-Smith*, has smaller and paler spots. — A woodland species like its allies. The ♀ flies slowly near the ground, whilst the ♂ has a swifter flight and generally remains at a considerable height.

chabrias. **P. chabrias** *Hew.* (1c). The forewing in both sexes has a row of submarginal spots, which however are often wanting in the ♀. The central area of the hindwing is situated somewhat further towards the margin than in *P. triopas*, consequently the cell-spot is smaller. — Upper Amazon, from Ega to Ecuador and Peru. Neither this nor the preceding species has so far been found in the large district between Obidos and Ega.

coelus. **P. coelus** *Boisd.* (♂ = *vercingetorix* *Oberth.*) (1d). Forewing with a white spot, obsolete at the margins, which fills up the extremity of the cell, and extends on to the disc. Hindwing with red band on the disc, in the ♂ composed of four spots, in the ♀ of six. — French Guiana, the ♂ in OBERTHÜR's Collection, one ♀ in the Paris Museum.

quadratus. **P. quadratus.** Forewing long; hindwing in both sexes with a band consisting of yellowish white spots on the disc close to the cell, and on the under surface in addition with a red spot at the hind angle. — In the name-typical form **quadratus** *Stgr.* (2b), of which only one ♂ is known, the forewing has a yellowish white spot before the 2. median. The specimen was taken near Manicoré on the Rio Madeira. — In **spoliatus** *Stgr.* neither sex has a spot on the forewing. Upper Amazon; rather rare, near Iquitos, Pebas, S. Paulo de Olivença and other places.

pizarro. **P. pizarro** *Stgr.* Abdomen in the ♂ quite black; in the ♀ with a red spot before the apex on the underside. Forewing without spots, also none in the fringes. Hindwing with whitish yellow area, which in the ♂ consists of three or four spots, in the ♀ of three to six. — Upper Amazon.

steinbachi. **P. steinbachi** *Rothsch.* (2a). This fine species has recently been discovered by J. STEINBACH in the eastern part of Bolivia. Forewing in both sexes with a large white spot before hindmargin; hindwing with a red band. Santa Cruz de la Sierra, between the end of February and June; also received from Mapiri.

klagesi. **P. klagesi** *Ehrm.* (2a). The ♂ of this peculiar little *Papilio* is not known; only four ♀♀ have been found. The hinder angle of the cell on the forewing is quite rounded; neither the fore- nor the hindwing has distinct fringe-spots. Forewing with a white band before the hindmargin; hindwing with a band composed of red spots. Abdomen entirely black, even at the tip. — Suapure, on the Caura, Orinoco, taken by S. M. KLAGES and his brother in February and March, 1899. Perhaps the species belongs to the *lysander*-group.

aeneas. **P. aeneas.** Palpi black, as in the preceding species. Abdomen in the ♀ with a small red spot beneath before the tip. Sexes very different. ♂ with green spot on the forewing; hindwing with red non-opalescent central area, not extending further towards the base than to the middle of the cell. In the ♀ the forewing is either entirely black, or bears one or more white obsolete spots on the margins. Guiana; Upper Orinoco; Amazon from Pará upwards; eastern slopes of the Andes of Peru and Bolivia. Several geographical forms. A woodland species, about whose earlier stages nothing is known. — **aeneas** *L.* (= *gargasus* *Hbn.*; *aeneides* *Esp.*; *bochus* *Luc.*) (2b) inhabits the three Guianas. The green spot of the ♂ is removed from the cell, and is usually wider before than behind the submedian vein. The ♀ occurs in two forms: ♀-f. **specularis** *R. & J.* has on the forewing a large white spot before the 1. median, and usually several smaller ones, of which one is in the cell. In the second form, ♀-f. **dido** *R. & J.*, the forewing has no white spots. — **marcius** *Hbn.* (2b) is the subspecies from the Lower Amazon. The ♂ is similar to that of *aeneas*, but the last red spot but one on the under surface is larger. We know only one form of the ♀; in this the white spot of the forewing usually extends to the 2. median, and the median red spots of the hindwing are close together. — **linus** *R. & J.* from the Middle Amazon (Santarem, Obidos, Massauary) was unknown to Bates. The red spots on the underside of the hindwing of the ♂ are paler than in the last subspecies, and stand closer together and nearer to the cell. In the ♀ the red spots are united into an uninterrupted band. — **damis** *R. & J.* inhabits East Peru. The green spot of the ♂ is larger than in the preceding forms, and the spots on the under surface of the hindwing are reddish white. The ♀ occurs in two forms: ♀-f. **pyromelas** *R. & J.* (2b) has entirely black forewing; the red spots of the hindwing are confluent, forming a band. In ♀-f. **eucharis** *R. & J.* the forewing has a large white area with undefined margins. — **locris** *R. & J.* is in the ♂ similar to the last subspecies, but the red spots on the hindwing are larger. The ♀ has always a white area on the forewing; the red spots on the hindwing are separated

from one another, the spot before the 1. median being the largest. Bolivia. — **bolivar** *Hew.* (2a) inhabits *bolivar*. the Upper Amazon and the Orinoco. The red area on the hindwing of the ♂ is small, and is whitish yellow on the under surface. Forewing of the ♀ black, with white spots on the fringes; hindwing with a whitish yellow area.

P. dardanus *Fabr.* (= *tros Fabr.*; *opleus Godt.*) (2c). Tailed. Forewing in the ♂ with a green *dardanus*. spot before the hindmargin; the red area of the hindwing not opalescent. ♀ with a white area on the forewing, with obsolete margins. — An exclusively Brazilian species, which hitherto is only known from the province of Rio de Janeiro.

P. orellana *Hew.* (2c). The most beautiful species of the *aeneas*-group. Forewing in both sexes *orellana*. black, bluish in a side-view, with white spots on the fringes. Hindwing in the ♂ with a very large red area, not opalescent; in the ♀ with a broad red band. — Upper Amazon, from Ega to Iquitos.

P. sesostris. Forewing in the ♂ with very large green area which touches the cell; hindwing either black or with a red spot before the hindmargin. Forewing of the ♀ with at least two white spots; the red band on the hindwing generally broad. Scent-organ of the ♂ with white wool, except at the base, which is black. Mexico to the Amazon, in three subspecies. — The northern form is **zestos** *Gray* (3a). The ♂ *zestos*. has always a red spot on the hindwing. In the ♀ the band on the upper surface of the hindwing is bright red. South Mexico to Costa Rica. — **tarquinius** *Boisd.* occurs from Panama to Ecuador and North Venezuela. *tarquinius*. The upper surface of the hindwing of the ♂ has mostly a red spot as in *zestos*, but the band on the under surface is more obliquely placed. In the ♀ the second white spot on the forewing is somewhat larger than in *zestos*, and the band on the under surface of the hindwing is nearer to the cell. — **sesostris** *Cr.* *sesostris*. (♀ = *tullus Cr.*) (2d) has very rarely a red spot on the upper surface of the hindwing of the ♂, and the spots on the under surface are placed somewhat nearer to the margin. In the ♀ the two white spots on the forewing are widely separated from the cell. Orinoco; Guiana; Pará to Peru; Bolivia; Goyaz.

This species is a strong flier, which appears never to leave the woods.

P. childrenae. The green area of the ♂ is larger than in *P. sesostris*, covering also a part of the cell. The ♀ has a transverse row of spots before the apex of the forewing, as well as two spots on the disc posteriorly. Distributed from Guatemala to Ecuador in two subspecies. — **childrenae** *Gray* (3a) is the *childrenae*. Central American form, which is found from Guatemala to Panama. Forewing of the ♂ with a white spot before the apex. Band on the hindwing of the ♀ bright red. — **oedippus** *Luc.* has in the ♂ no white spot *oedippus*. before the apex of the forewing, or only a very small one. In the ♀ the band on the hindwing is a somewhat yellowish red on the inner side. Colombia and Ecuador.

P. erlaces. Palpi always black. Fringes of both wings spotted with white. Forewing of the ♂ with a gray-green spot before the hindmargin; hindwing with three red, strongly opalescent spots. In the ♀ the margin of the 8. abdominal segment red all round; forewing with large cell-spot and 2 or 3 discal spots. Ecuador to Bolivia. — **lacydes** *Hew.* (♀ = *equestris Oberth.*) (3b) has rarely a white spot on the *lacydes*. forewing of the ♂, the spots on the under surface of the hindwing small, almost entirely white. In the ♀ the cell-spot of the forewing large; band of the hindwing white. In Eastern Ecuador. — **xanthias** *R. & J.* *xanthias*. (3b). Forewing of the ♂ almost always with one or two white spots; spots on the under surface of the hindwing varying from white to red. Cell-spot of the ♀ triangular, second discal spot larger than the first; band on the hindwing pale yellow. North-east Peru, southwards to Huánuco. — **erlaces** *Gray* (3a) is the *erlaces*. most southerly form. It inhabits South-east Peru, Bolivia and North Argentina. Forewing of the ♂ rarely without large white spots; hindwing on the underside with 5—7 red spots. Forewing of the ♀ usually with 3 white spots besides the cell-spot; band on the hindwing red.

P. burchellanus *Westw.* (= *socama Schaus*). Sexes similar. Palpi black. Forewing black, only with *burchellanus*. fringe-spots. Hindwing with a row of separated red discal spots. Resembles *P. panthous Cr.* (3b), which however has red marginal spots. — In the interior of Brazil: Farinhapodre, Goyaz; rare in collections. On pl. 3 a specimen of *panthous* is figured by oversight as *burchellanus*.

P. drucei *Bthr.* (♀ = *opalinus Bthr.*) (3b). Palpi generally black, sometimes red. Forewing in the ♂ *drucei*. with a green spot, separated from the cell; in the ♀ unicolorous, but the fringes spotted. Hindwing in the ♂ with 3, occasionally 4, opalescent spots; in the ♀ with a band composed of 5—7 spots, sometimes rather strongly opalescent. Eighth abdominal segment of the ♀ edged with red all round. — Upper and Middle Amazon, and the eastern slopes of the Andes from Ecuador to Bolivia.

P. cutorina *Stgr.* (♀ = *mazeppa Grose-Smith*) (3c). Palpi red. Forewing of the ♂ with a green *cutorina*. spot; in the ♀ without spot, the fringes spotted with white. Hindwing in the ♂ with two contiguous red spots on the upper surface, the spots on the under surface yellowish white; in the ♀ the wing has a yellowish white band on both surfaces; 2. and 3. radials close together, the transverse vein between them not oblique. — Upper Amazon and slopes of the Andes of Ecuador and Peru.

P. phosphorus. Palpi red. Forewing somewhat transparent distally; ♂ with dirty-green spot; hindwing rather strongly dentate, the red spots remote from the cell. Tibiae armed with spines, not thickened.

♀ with grey-green area on the forewing before the hindmargin, which occurs in no other ♀ of the *Aristolochia-Papilio*. Colombia; Guiana; Lower Amazon; East Peru; perhaps more widely distributed. A rare insect; probably a swamp species which escapes observation. Two subspecies: — *phosphorus* *Bates* (3c) occurs in British Guiana and at the Lower Amazon. The green spot on the forewing of the ♂ is narrow and separated from the cell. The forewing of the ♀ has a row of 4 white spots on the grey-green area (always?). — *gratianus* *Heur.* (3c) inhabits Colombia and East Peru. The green spot on the forewing of the ♂ is much broader than in the preceding form; hindwing with only 3, or rarely 4, red spots, the series not curved. Forewing of the ♀ with two white spots; the posterior spots of the hindwing large.

P. vertumnus. Palpi red. Forewing in the ♂ with a green spot; in the ♀ unicolorous or spotted with white. Hindwing of the ♂ with triangular red area, which consists of 3 or 4 spots, of which the posterior one is usually the longest; in the ♀ with a broad red band, consisting of 5—7 spots, of which the four posterior ones are more or less completely connected. One of the commonest species, which is often met with in the woods, settling in damp places at the edge of the brooks. Distributed from Colombia to Bolivia, Guiana and Pará, but not yet found in Venezuela and Brazil proper.*) — *yuracares* *R. & J.* is the Bolivian subspecies. Only the ♂ is known. The green spot touches the cell, and encloses at least one white spot. Hindwing with at least 4 red spots, of which the anterior two are separated; 5 small spots on the under surface. Found by J. STEINBACH from January to April. — *autumnus* *Stgr.* (3d). ♂: the green spot larger than in the preceding; hindwing with 3 red spots; 4 small red spots on the under surface. ♀: forewing with very large yellowish area; cell-spot especially large. East Peru: Chanchamayo; undoubtedly extending further south. — *bogotanus* *Fldr.* Only the ♂ known to us. Forewing without white spot; hindwing with rather large red area, the spots on the under surface small. Rio Palcazu northwards to "Bogotá". — *diceros* *Gray* (= *cixius* *Gray*; ♂ = *cutora* *Gray*). ♂: forewing usually without white spots in the green area; when present they are transverse, and somewhat obliquely placed; red area of the hindwing smaller than in the preceding forms, the spots on the under surface on the contrary generally larger. ♀: forewing with chalky-white area, consisting of 2—4 spots, occasionally only one double spot present. Pará to Iquitos. — *vertumnus* *Cr.* (3c) is distinguished in the ♂ from all the other forms of the species by the short-haired middle and hind tibiae. The ♀ as in the Amazon form, or the forewing with only one white spot, of which there is sometimes merely an indication. Guiana.

P. lycimenes. ♂: somewhat smaller than *P. vertumnus*, the red area of the hindwing less triangular and its last spot smaller. ♀: forewing slightly transparent at the apex; the spots somewhat yellowish, not pure white, the cell-spot usually large and extended across the cell; band of the hindwing less bright red than in *P. vertumnus*. Tibiae of the ♂ not thickened. Guatemala to Ecuador, in several subspecies. — *lycimenes* *Boisd.* is the Central American form. Forewing with a large green spot, which almost always encloses at least one white spot; often a spot in the cell; hindwing with 4—6 red spots. In the ♀ the yellowish white spot before the 1. median much larger than the preceding one; band of the hindwing broad, almost always a uniform bright red. Guatemala to Panama; also on the small islands on the west coast of the Republic of Panama. — *erythrus* *R. & J.* (3d). ♂: the green spot broader than in the preceding form, reaching to the hindmargin of the wing. ♀: the spot before the 1. median of the forewing larger than in the preceding form; the band of the hindwing paler. Central and East Colombia and North Venezuela. — *paralius* *R. & J.* (4a). Small. ♂: forewing with round yellow-white spot before the 2. median; band of the hindwing short and narrow. ♀: spot on the forewing purer white than in the previous subspecies, the cell-spot reduced; the spot before the 2. median the largest; band of the hindwing almost straight. West Ecuador.

P. erithalion. ♂: tibiae not thickened. Hindwing without distinct red spot behind the 2. median on the upper surface. ♀: the spot before the 1. median of the forewing smaller than the preceding spot; band on the hindwing broad, pale on the innerside. Costa Rica to North Venezuela. — *zeuxis* *Luc.* (= *rhameses* *Doubl.*, *rhesus* *Koll.*, *rhameses* *Fldr.*, *abilis* *Fldr.*, *rhameses* *Boisd.*) (4a). ♂: the green area much narrowed anteriorly, enclosing a large white spot before the 2. median; hindwing with 2 or 3 small red spots. ♀: the posterior spot of the forewing larger than the preceding one. North Venezuela and eastern side of the Cordillera of Bogotá. — *erithalion* *Boisd.* (4a) from Central Colombia (Rio Magdalena) has in the ♂ rarely a white spot on the forewing, which is placed before the 1. median or between the radials. ♀: the spot before the 1. median smaller than the preceding one; generally a few small spots outside the cell. — *cauca* *Oberth.* ♂: the green area of the forewing wanting or merely indicated. ♀: band on the hindwing narrow, curved, separated from the cell. Cauca valley. — *sadyattes* *Druce* (4a). ♂: the green area very variable, generally reduced, often wanting; all specimens with at least one white spot, which is placed before or behind the 3. radial, often a green spot in the cell. ♀: band of the hindwing almost unicolorous bright red. Costa Rica to Panama.

*) Faunistically we understand by Brazil the eastern part of the continent from the province of Goyaz and Pernambuco to Rio Grande do Sul. In this district we find a fauna which is quite different in many respects from that of the rest of South America.

P. polyzelus. ♂ ♀: forewing without green area, rarely with a small white spot in the ♂; band of the hindwing narrow, nearer to the margin than to the cell. Mexico to Honduras; common. — In *polyzelus polyzelus* Fldr. (= *candezei* Borre) (4a), from East and South Mexico, Guatemala and Honduras, the tibiae of the ♂ are not thickened, resembling those of the ♀. — In *trichopus* R. & J., from West Mexico, the tibiae of the ♂ are thickened and bear fine hairs, as well as the 1. segment of the tarsi; the band of the hindwing is on the whole broader than in the preceding.

P. iphidamas. ♂: tibiae and 1. segment of the tarsi thickened and covered with fine hairs. ♀: forewing at the margin less deep black than in *P. erithalion*. Mexico to Ecuador and North Venezuela. A common species, which is not easy to distinguish from *P. erithalion* and *P. lycimenes*, and is consequently often mistaken for them. — **iphidamas** F. (= *panares* Gray, *achelous* Hopff., *incandescens* Bthr.) is the *iphidamas*. Central American form. ♂: forewing distally not transparent; the green area usually reduced, always enclosing one or two white spots; often a white spot in the cell; band of the hindwing gradually widened posteriorly, a narrow spot behind the 2. median. ♀: cell-spot on the forewing large, usually some small spots beyond the cell; the spot before the 2. median smaller than the preceding one, or obliquely cut off towards the base; band of the hindwing almost unicolorous bright red, its inner margin evenly curved. South Mexico to Panama. — **phalias** R. & J. (4b). ♂: the green area widest posteriorly, reaching to the hindmargin; hindwing with three red spots separate from the cell. ♀: forewing slightly transparent at the apex; cell-spot very large; the spot before the 1. median much larger than the preceding one; band of the hindwing very broad, pale on the inner side. Colombia: Magdalena Valley and Cordillera of Bogotá. — **elatos** R. & J. ♂: the green area smaller than in the preceding subspecies; hindwing with three small red spots. Cauca Valley. — **calogyna** R. & J. (4b). ♂: forewing exteriorly somewhat more thickly scaled than in *phalias* and *elatos*, usually a white spot before the 2. median; hindwing with 3 small red spots, close together. ♀: the spot before the 1. median of the forewing larger than the preceding one; band of the hindwing bright red, its inner margin usually white. West Ecuador and west coast of Colombia. — **teneates** R. & J. ♂: the green area narrow, separated from the cell, usually enclosing one or two white spots. ♀ not known with certainty. North Venezuela and North Colombia.

P. anchises. Apex of the forewing distinctly, though only slightly, transparent. ♂: tibiae and 1. segment of the tarsi thickened and covered with fine hairs; hindwing blue, strongly iridescent. ♀: the spot before the 1. median larger than the preceding spot. Colombia to South Brazil and Paraguay. The black-brown larva has on the first and on the penultimate segment two dorsal spots, and on each of the thoracic segments and the 8. and 9. abdominals one lateral spot; on the 6. and 7. segments is an oblique lateral band, sometimes broken up into spots. The dorsal humps on the pupa are three-edged and rather small. — **alyattes** Fldr. (4b, c). ♂: the green area separate from the cell, enclosing at least one white spot, placed before the 2. median, many specimens with a second spot before the 1. median; the last spot on the inner surface of the hindwing larger than in *P. iphidamas phalias*. ♀: cell-spot narrow; band of the hindwing entering the end of the cell, black outer margin wider than in *iphidamas*. Colombia, in the Magdalena Valley and probably on both sides of the Cordillera of Bogotá. — **serapis** Boisd. ♂: the green area very long and narrow, only a little wider posteriorly than anteriorly; band of the hindwing consisting of at least five spots. ♀: cell-spot large, almost triangular, the spot before the 1. median very large and the band on the hindwing very broad. North Colombia. The distribution of *serapis* and *alyattes* is only very imperfectly known. — **osyris** Fldr. (= *xenares* Fldr., *toxaris* Fldr., *severus* Fldr.) (4b). ♂: the green area of the forewing and the band of the hindwing broader than in *serapis*. ♀: the cell-spot usually extending transversely across the cell; the band of the hindwing very little paler internally than externally. Venezuela. — **cymochles** Doubl. (= *anacharsis* Fldr.). ♂: forewing with one to three spots; hindwing with three, occasionally four, red spots. ♀: spots of the forewing purer white than in the preceding subspecies; cell-spot small; band of the hindwing almost unicolorous red, broadest in the middle. Trinidad, Paria Peninsula and Orinoco. — **anchises** L. (= *telmosis* Bates, *toxaris* Fldr.) (4c). ♂: green area narrow, sometimes wanting; hindwing more strongly dentate than in the other forms, the red spots usually widely separated. ♀: forewing without cell-spot or with merely a cell-streak, often without any spots; hindwing with a row of six or seven red spots, separated from one another. Dutch and French Guiana. — **thelios** Gray (= *hierocles* Gray, *aglaope* Gray [partim]) (5a). ♂: the green area triangular, enclosing one or two rather large white spots; hindwing with three or four red spots, of which the one before the 2. median is the largest. ♀: forewing with at least two white spots, the one before the 2. median the largest; hindwing with seven or eight separated spots. Lower Amazon, from Pará to Santarem; occurs in dry, sandy places in the forest, not in the swamps. — **etias** R. & J. ♂: palpi sometimes almost without red scales; hindwing without a red spot before the 1. radial, or this spot very small. ♀: spots on the forewing pure white, cell-spot very small, two large white spots before and behind the 1. median. East Bolivia, found by J. STEINBACH in December, January and April-May. — **orbignyanus** Luc. (4c). The red band on the hindwing of the ♂ is uniformly curved and becomes gradually narrower anteriorly; the forewing has at least one large white spot. In the ♀ a spot in the cell of the forewing and at least two on the disc; hindwing with a band from

the subcostal to the hindmargin. Paraguay; northern part of Entre Rios; Matto Grosso; Goyaz. — *foetterlei*. **foetterlei** *H. & J.* (4c). White spots on the forewing of both sexes very large and the band on the hindwing very broad. In the interior of the province of S'ao Paulo.

hedae. **P. hedae** *Foett.* (5a). Only one ♀ known; palpi red; on the forewing a very broad white band, with the edges finely crenulating for the most part pale red, whitish towards the base, the marginal spots slightly yellowish. Icarahy, near Rio de Janeiro.

nephalion. **P. nephalion** *Godt.* (= *osymanduas Hbn.*, *proteus Boisd.*, *stilbon Koll.*, *haemon Fldr.*) (4d, 2d). Marginal tooth at the 3. radial of the hindwing projecting more than in *P. anchises* *L.* Forewing in both sexes with two or three large white spots. Hindwing of the ♂ with three red spots on the upper surface, and usually a fourth separated from them; in the ♀ with a band composed of five spots, and commonly a sixth or even a seventh (very small) spot. The larva is brown-black, with a yellow longitudinal stripe on the sides. The butterfly is not rare, and occurs in Brazil proper southwards to Rio Grande do Sul, as well as in Matto Grosso, Paraguay and the adjoining parts of Argentina. A forest-species.

Lysander-Group.

The following species, which form the *lysander*-group, have red instead of white marginal spots. The hind tibiae of the ♂ are always dilated and with fine hairs. The species occur together with those of the *aeneas*-group, and are sometimes very common. The red spots on the hindwing have no opalescent gloss.

P. panthonus. Forewing in both sexes black, with reddish marginal spots; hindwing with a regularly curved row of separated red spots. Scent-wool white. Guiana and Brazil, in two subspecies. —

numa. **numa** *Boisd.* (= *jaguaræ Foett.*), from Brazil (São Paulo and Minas Geraes), has small, widely separated spots. — In **panthonus** *Cr.* (3b, 5a), from the three Guianas, the spots on the hindwing are somewhat larger. This form most probably occurs also on the north side of the Lower Amazon.

aglaope. **P. aglaope** *Gray.* ♂: forewing with a blue-green band, which has at least one large white spot, placed before the 2. median; hindwing with four spots, separate from the cell. The ♀ occurs in two forms: *lysimachus*. ♀-f. **lysimachus** *Hour.* has on the forewing a straight row of three spots; ♀-f. **callicles** *Bates* has on the *callicles*. forewing a large spot behind the 1. median, a smaller one before it, and a streak in the cell. — This species is rather rare; it has hitherto only been taken on the Lower Amazon, in South-east Peru and in *euristeus*. eastern Bolivia. — GRAMER has figured as **euristeus** a butterfly from Surinam which perhaps also belongs here, but the figure is too bad to be referred with certainty to any one species. Is it the ♂ of *klagesi* *Ehrm.*?

lysander. **P. lysander** *Cr.* (= *phrynichus Fldr.*). ♂ with white scent-wool in the fold of the hindwing. Outer margin of the forewing in the ♀ rounded; the last two red spots on the hindwing separated, standing *parsodes*. obliquely one under the other; ♀-f. **parsodes** *Gray* (= *sonoria Gray*) has a large white area on the *arbates*. forewing, composed of several spots; in the ♀-f. **arbates** *Stoll* (= *anaximenes Fldr.*) the forewing has only *brissonius*. one white spot; whilst in the ♀-f. **brissonius** *Gray* (5b) the forewing has no white spot at all. A ♂ with *bari*. yellow instead of red spots on the forewing has been described as ab. **bari** *Oberth.* — This species is known from the whole of the Amazon, East Peru and East Ecuador, as well as from the Guianas and Bogotá; it has not hitherto been found in Bolivia nor in Brazil proper.

P. echemon resembles the preceding species; but the forewing is narrower, the outer margin being incurved in the ♂, straight in the ♀, the cell of the forewing is narrower at its extremity, the 3. radial of the hindwing is usually much nearer to the 2. radial than to the 1. median, and the fold of the hindwing in the ♂ has no white wool. On the Lower and Middle Amazon and in the Guianas. Two subspecies. — *echemon*. HÜBNER's figures agree with the form from the Amazon: in the ♂ **echemon** *Hbn.* (= *echelus Hbn.*) the blue-green band of the forewing is narrow and placed, like the white band of the ♀, separate from the cell. *ergeteles*. From Pará to Santarem. — **ergeteles** *Gray* (= *echephron Bates*, *echion Bates*, *polyphron Fldr.*) has in the ♂ a broader blue-green band, and in the ♀ the white spot before the 2. median is contiguous to the cell, or the forewing is without spots. ♀-f. **ergeteles** *Gray* is the form of the ♀ with a white area; in the ♀-f. *pisander*. **pisander** *Fldr.* the white spots are only indicated by a few white scales. From Obidos to the Rio Negro, north side of the Amazon; Guiana. — Whilst *P. lysander* is a swamp species and flies heavily over the wettest places in the shade of the woods, *P. echemon* prefers drier localities in the woods, and is often found on the flowers which hang down from the trees over the narrow paths in the forests.

P. neophilus. In the ♂ the cell of the hindwing on the upper surface is red nearly to the base. In both sexes the 2. median of the hindwing arises at the same height as the subcostal. Colombia to Paraguay and South Brazil, but not from Rio de Janeiro to Pernambuco, where *P. zacynthus* occurs. — *eurybates*. **eurybates** *Gray* (= *euphales Gray*) (5c). ♂ with large white spots on the forewing; the red spots on the hindwing not blackish towards the base, with the exception of the first and last, the middle ones touching the cell on the under surface. ♀ with 2 white spots between the 3. radial and 2. median, rarely with the spots merely indicated, the red band on the hindwing broad. São Paulo and Matto Grosso; Paraguay

(transition to the next form). — **consus** *R. & J.* ♂: the green area between the 2. median longer than *consus*. broad, the white spot before the 2. median rounded, usually smaller than the preceding spot; on the hindwing the cell-spot and the part of the discal spot next to the cell are blackish red; the spots on the underside smaller than in *eurybates*. In the ♀ the white spots are large; the band on the hindwing is usually separate from the cell. East Bolivia. — **olivencius** *Bates* (5c). White spots on the forewing in *olivencius*. both sexes small or indistinct; the red spots on the hindwing in the ♂ long on the upper surface, short on the under. In the ♀-ab. **anaximenes** *Fldr.* the spots of the hindwing are very long. East Peru to the *anaximenes*. Cordillera of Bogotá, and on the Amazon downwards to the Rio Negro. — **ecbolius** *R. & J.* ♂: the green *ecbolius* spot behind the 2. median of the forewing about as long as broad, the white spot before this vein distinct and transverse as the preceding spot; the red spots on the hindwing shorter than in *olivencius*. In the ♀ the forewing has a large white spot before the 2. median and another before the 1. median, the outer margin of these spots almost parallel with the outer margin of the wing. Lower Amazon, upwards to Obidos. — **neophilus** *Hbn.* (= *gargasus* *Hbn.* [partim], *aeneides* *Esp.* [partim]), the first described form, *neophilus*. inhabits the Guianas. ♂: the green area is broader and the red spots on the underside of the hindwing smaller than in the ♂ of *ecbolius*. In the ♀ there are no white spots on the forewing, or they are small, rarely are they large; the third spot on the hindwing longer than the others, the spots on the upper surface further from the margin than in *olivencius*. — **parianus** *R. & J.* from Trinidad, Cumana and the Orinoco. *parianus*. The green area of the ♂ behind the 2. median longer than it is broad, enclosing three white spots; the spots on the under surface of the hindwing paler than in the Bolivian form, to which *parianus* comes near, the spot before the 2. median placed close to the cell. In the ♀ the band of the hindwing is somewhat more curved than in the other subspecies; the narrow middle spots are placed close to the cell on both surfaces.

P. zacyanthus. Band on the forewing in the ♂ greenish blue. The spots on the under surface of the hindwing of the ♀ paler than in *P. neophilus*. Brazil, from Rio de Janeiro northwards, in two geographical forms. Not rare in damp localities overgrown with bushes. The larva is grey-brown, with a yellow lateral stripe. — The form from the province of Rio de Janeiro, **zacyanthus** *F.* (5b), occurs in the *zacyanthus*. neighbourhood of the town of Rio, but is much rarer than *P. nephalion*. The forewing is not transparent at the apex; the ♀ has a spot in the cell of the forewing. — The northern form, from Pernambuco, Bahia and Rio Tapajos, is **polymetus** *Godt.* (5b). The forewing is transparent at the apex and the ♀ has no spot *polymetus*. in the cell, or only a very small one.

eurymedes ^{*new name*} **P. arcas.** In the ♂ the cell of the hindwing above is red from about the middle; in the ♀ the forewing has a large white spot placed obliquely across the cell. Mexico to the Guianas and Colombia, not found further south. — **mylotes** *Bates* (= *docimus* *Gray*, *caleli* *Reak.*, *tonila* *Reak.*, *alcamedes* *Fldr.*, *mylotes*. *aristomenes* *Fldr.*) (5d). ♂: the green spot before the 1. median long and usually enclosing a white spot; the cell mostly also with a white or green spot, no green streak at the hindmargin. The band on the hindwing in the ♀ separate from the cell and bright red on both surfaces. Mexico to Costa Rica; very common in the lowlands. — **mycale** *Godm. & Salv.*, from Panama and the small islands on the Pacific coast *mycale*. of that Republic, forms a transition from the preceding to the following form. In the ♂ the green area before the 2. median is always large; the cell-spot on the hindwing and the adjoining parts of the discal spot are tinged with brown. The band on the hindwing of the ♀ is bright red and usually placed close to the cell. — **arriphus** *Boisd.* The forewing of the ♂ has almost always a green spot also before the *arriphus*. 1. median; hindwing with a cell-spot on the upper surface, the band sometimes pale and narrow: ♂-ab. **agathokles** *Koll.* In the ♀ the band on the hindwing is pale red and includes also the extremity of the *agathokles*. cell. Colombia, from the Rio Magdalena and Rio Meta; common in "Bogotá" collections. — **antheas** *antheas*. *R. & J.* The green band of the ♂ reduced, no spot before the 1. median; the band of the hindwing usually very pale, in the ♀ likewise paler than in *arriphus* and mostly shorter. Cauca Valley. — **arcas** *Cr.* *arcas*. (♂ = *eurymedes* *Cr.*) from Venezuela and Guiana. The red band of the hindwing in both sexes is broader than in the other subspecies; in the ♂ the extremity of the cell of the hindwing is red also beneath, and in the ♀ the cell-spot is much larger than in *arriphus*.

P. timias. Both sexes with two large white spots on the forewing, in the ♂ placed in the green area; red cell-spot on the hindwing in the ♂ large; ♀ with a rather small cell-spot or none at all. West Ecuador, from Guayaquil upwards. Many northern species occur in this district which are wanting in East Ecuador and Peru. — GRAY'S **timias** (5d), whose ♀ was named *bimaculatus* by HEWITSON, occurs about *timias*. Guayaquil and in the neighbouring districts. The cell of the forewing in the ♂ has no distinct green spot; the first spot on the under surface of the hindwing is at least as large as the last. In the ♀ also there is no distinct cell-spot on the forewing and the discal spots are small. — **potone** *R. & J.* has in both sexes *potone*. a distinct cell-spot on the forewing. Paramba and Ambato, taken by ROSENBERG at a height of 3500 ft.

Section B.

The following *Aristolochia*-Papilios are very different from the preceding groups. The body is never spotted with bright red, and the wings never have bright red spots or bands. The antennae have no deep sensory grooves

and their terminal segment is very short. The cell of the hindwing is rounded at the apex and its lower angle is at least as large as the upper. The scent-organ on the hindwing of the ♂ is never woolly and the tibiae are never thickened. — The larva bears on the first thoracic segment strongly elongated fleshy protuberances, and the dorsal humps of the pupa are narrow, laterally compressed and rather long.

Polydamas-Group.

This *polydamas*-group also differs essentially in habits from the red-spotted butterflies. They are inhabitants of the open country, seldom met with in the shade of the forest. The ♂♂, which are quick fliers, are fond of resting on damp sand or mud to imbibe the moisture, whilst the ♀♀ visit several common species of flowers.

P. philenor is a well-known North American butterfly, distinguished by the bright green or blue gloss of the outer part of the hindwing beneath. Its original home was undoubtedly the Southern Atlantic States, whence it has spread to Mexico and again in the west as far as Northern California. In the central part of the United States, from Colorado northwards, the species is absent; in the east, on the contrary, it extends as far as the south of Canada, where it is met with from time to time as an immigrant. Its distribution northwards, in places where the original food-plant (*Aristolochia serpentaria*) is not found, has

orsua. been made possible by the cultivation of *Aristolochia siphon* as an ornamental plant. — **orsua** *Godm. & Salv.*
philenor. is a small tailless form from the Tres Marias Islands with strongly glossy hindwing. — **philenor** *L.* (= astinous *Drury*) (6a) inhabits the United States and Mexico. The species varies geographically but little, yet some of the Mexican specimens are tailless, which seems never to occur in North America. This
acauda. ab. mex. **acauda** *Oberth.* (= nezahualcoyotl *Streck.*, corbis *Godm. & Salv.*) occurs together with ordinary
wasmuthi. specimens. As ab. **wasmuthi** *Weeks* a colour variety is described which recalls the celebrated ab. *calverleyi* of *P. polyxenes* *Fabr.* In this aberration the marginal spots are enlarged into a broad band. Specimens
obsoleta. without submarginal spots on the upper surface are ab. **obsoleta** *Ehrm.* The species has several generations in the Southern States. The specimens of the spring brood are in general more rough-haired than those of the summer. The butterfly is very common, and flies in great numbers about flowering trees, or sips at the flowers of low plants or at wayside pools. In feeding and flying the wings have a quivering motion as in the allied species.

devilliers. **P. devilliers** *Godt.* (6a). Hitherto known with certainty only from Cuba; the older authors assigned it to Florida also, which is perhaps due to an error. Tailed. Forewing with a submarginal row of white spots; hindwing on the upper surface with a submarginal band, and on the under with one or more silver spots.

zetes. **P. zetes** *Westw.* (6a) has on the upper surface of both wings a yellowish band, and on the under surface of the hindwing a silver band. Haiti; only a few specimens in collections.

The following species are all without tails. To some extent the form of the wings recalls the so-called *Ornithoptera* from the Oriental Region.

streckerianus. **P. streckerianus** *Hömr.* (= mathani *Oberth.*) (6a) is a native of the dry open country of North Peru. The spots on the body are greenish yellow. Forewing without band, the band on the hindwing very variable, opalescent in the ♀.

archidamas. **P. archidamas** *Boisd.* (= bias *Kirby*, ex *Roger*) (6b). The spots on the body reddish. Upper surface of both wings with a band composed of spots; under surface of the hindwing for the most part dirty white. Chile; all the year round in the open coast districts. The earlier stages are very similar to those of *P. polydamas*.

P. polydamas. The spots on the body reddish; upper surface of both wings with a band composed of spots; under surface of the hindwing black-brown, with red or yellowish red submarginal spots. Distributed from Virginia to Argentina; varying but little geographically on the continent, on the Greater and Lesser Antilles on the contrary developed into a different form on almost every island. One of the commonest *Papilios* on the continent; an inhabitant of cultivated ground which accompanies the settler everywhere; it is especially common where the ground cleared for cultivation has been again neglected. The larva varies from brown-yellow to dark black-brown; the tubercles are long, in dark specimens red. The pupa is strongly

vincentius. curved, and has three long, compressed humps on the abdomen; the thoracic horn is long. — **vincentius** *R. & J.* Above like the continental form; under surface of the hindwing with white costal streak; sub-

lucianus. marginal spots large. St. Vincent. — **lucianus** *R. & J.* The band on the upper surface broad; under

xenodamas. surface of the hindwing with costal streak at the base; submarginal spots large. St. Lucia. — **xenodamas** *Hbn.* (= cebriones *Dalm.*, eurydamas *Kirby*, ex *Roger*). Band on the upper surface of the hindwing broad, placed close to the cell; under surface of the hindwing at the base with a large bluish grey spot and costal

dominicus. streak. Martinique; formerly erroneously given as inhabiting Brazil. — **dominicus** *R. & J.* The posterior spots on the upper surface of the forewing smaller than in *xenodamas*; band on the hindwing curved. Under

neodamas. surface of the hindwing with costal streak, but without the large spot below it. Dominica. — **neodamas** *Lac.* The upper spots of the band of the forewing wanting or small, the hinder spots further from the

antiquus. margin than in the preceding forms. Band on the hindwing almost straight. Guadeloupe. — **antiquus**

R. & J. Similar to the next form; the four anterior spots of the band of the forewing small; band on the hindwing narrower than in the next subspecies; submarginal spots on the under surface of the hindwing large, yellowish red. Antigua. — **thyamus** *R. & J.* Similar to *polydamas*; submarginal spots on the under surface of the hindwing much more yellowish than in the continental subspecies. St. Thomas. — **lucayus** *R. & J.* Under surface paler than in *P. polydamas*; the white transverse streak at the anal angle of the hindwing extending at least beyond the 2. median; the red submarginal spots as in the continental form, but larger. Bahamas. — **polydamas** *L.* (6b) is the continental form, which occurs from Georgia to Argentina. It is also found on Cuba, but the Cuban specimens are usually distinguished by the deeper black marginal area on the under surface of the hindwing. The band on the upper surface varies much in breadth. The submarginal spots on the under surface of the hindwing are always narrow and red. **polycrates** *Hopff.* (— *hypodamas* *Guen.*) differs from the preceding form on the upper surface principally in the more distal position of the spot before the 2. median on the hindwing, and on the under surface in the large silver spots which stand at some of the red ones. The harpe of the ♂ has only one tooth instead of the two of all the preceding forms. Haiti and probably Porto Rico. — **jamaicensis** *R. & J.* is very similar to *polycrates*, but the submarginal spots on the under surface of the hindwing are larger and the silver spots connected with them smaller. Jamaica.

P. philetas *Hew.* (6b). Abdomen of the ♂ yellowish white above. Under surface of the hindwing greenish yellow, with red submarginal spots. South Ecuador and North Peru.

P. madyes. Similar to the previous species; submarginal spots on the under surface of the hindwing yellow. The scent-scales different in the geographical forms, which is also the case in some of the other species of the *polydamas*-group. Peru and Bolivia. — **plinius** *Weym.* from North Peru. Forewing above with four small spots. Hindwing beneath ochre yellow (discoloured?); submarginal spots small. Only one specimen known; found by STÜBEL between Moyabamba and Chachapoyas. — **chlorodamas** *Guen.* (= *marsyas* *Stgr.*), the commonest form in collections. Bands of spots on the upper surface broad, on the forewing white (♂♂, ♀♀) or yellow (♂♂). In Huánuco and Junin, East Peru. — **crispus** *R. & J.* Spots on the upper surface much smaller than in *chlorodamas*. South-East Peru. — **madyes** *Doubl.* Under surface of the hindwing streaked with black on the veins. Bolivia. — **tucumanus** *R. & J.* (6b), like *madyes*, but the apex of the forewing beneath not washed over with yellow; hindwing beneath smoky brown. Tucuman.

P. polystictus (= *protodamas* *auct.*). Forewing above with three to seven submarginal spots; hindwing with two rows of spots. Abdomen in the ♂ yellowish white above. Brazil, Argentina and Paraguay. Larva similar to that of *P. polydamas*; tubercles shorter, never red. Thoracic horn of the pupa long, inclined somewhat forwards, dorsum of the pupa behind the horn more or less suffused with yellow. Larva gregarious in its earlier stages. This common butterfly flies in open spaces in the forest and on its borders, and is especially fond of feeding on the flowers of Lantana. The food-plant of the larva grows in woods and on the banks of rivers. — In **janira** *R. & J.* the spots on the upper surface are large. Rio de Janeiro; Minas Geraës. — In **polystictus** *Bth.* (6b) the spots are smaller and sometimes partly obsolete. São Paulo to Rio Grande do Sul; Paraguay; Argentina.

P. eracon *Godm. & Salv.* (6c). Forewing with a row of submarginal spots. Hindwing with a uniformly curved band of spots, placed about midway between the cell and the outer margin. Under surface of the hindwing with red submarginal spots, each with a yellowish white dot at the outer side. West Mexico, hitherto only known from Colima and the province of Guerrero.

P. belus. Forewing of the ♂ without white spots on the upper surface; hindwing with one to seven white spots on the disc, the first of which is always large; the forewing of the ♀ is similar to that of the ♂ or it has a large pale yellow area. Hindwing beneath in both sexes with white dots outside the red submarginal spots. The ♂ is called by BATES a swift and bold flier; the ♀ with yellow area on the forewing he found on flowers at the edge of the forest. The ♀♀ of this, as also of the following species, are much more rarely caught than the ♂♂. — **chalceus** *R. & J.*, from the province of Guerrero, West Mexico, has an almost straight band on the hindwing, and on the under surface there is before the subcostal nervure a red submarginal spot, which is wanting in the other subspecies. — **varus** *Koll.* ♂: hindwing with a band of spots diminishing in width posteriorly. The ♀ occurs in two forms. The common form is ♀-f. **latinus** *Fldr.*, it is similar to the ♂, but the forewing has some submarginal spots and the first spot of the band of the hindwing is about as large as the second. The very rare form with large yellowish area on the forewing, occupying the extremity of the cell and the adjacent part of the disc, is ♀-f. **varus** *Koll.* Distributed from Guatemala to North-East Ecuador and North Venezuela: the ♂ common in Bogotá-collections. — **belus** *Cr.* (6c) is the form which inhabits the Guianas, the Amazons, East Peru and Goyaz. In the ♂ the hindwing has usually only one white spot, yet specimens occur which have a row of small spots in the disc. Two forms of the ♀ are known; ♀-f. **belus** *Cr.* (= *caburi* *Kaye*) is similar to the ♂ and has on the hindwing either only one spot or a complete row; in ab. **amulius** *Esp.* the spots on the under

surface of the hindwing are yellow (only known from ESPER's and MARTYN's figures). The second variety *amazonis*. of the ♀ is ♀-f. **amazonis** *R. & J.* (6c); it has a yellow area on the forewing like the ♀-f. *varus* of the sub-
belemus. species *varus* *Koll.* — **belemus** *Bates* from the south side of the Lower Amazon has a straight band on the
codiabamba. hindwing; only the form of the ♀ similar to the ♂ is known. — **cochabamba** *Weeks*. ♂: hindwing usually
 with a broad straight macular band; sometimes the last five spots small, very rarely wanting. Scent-scales
 short as in the Mexican subspecies. The ♀ is not known. South-East Peru; Bolivia.

P. laodamas. Similar to the preceding species. Hindwing above with a broad macular band; the
procas. red submarginal spots on the under surface narrow, not accompanied by white dots. The ♀ resembles the ♂,
 but the middle spots on the hindwing are large, whilst the first is small. Mexico to Colombia. — **procas**
Godm. & Salv. ♂: the band on the hindwing is usually contiguous to the cell or crosses its extremity, it
topas. is rarely separated from the cell (ab. **topas** *Godm. & Salv.*). ♀: band on the hindwing usually occupying
 the extremity of the cell. West Mexico, known from the provinces of Michoacan, Jalisco and Guerrero. —
copanae. **copanae** *Reak.* (= *chrysodamas* *Bates*). Band on the hindwing in ♂♀ separate from the cell; the red sub-
rhypidius. marginal spots on the under surface of the hindwing narrower than in *procas*. Scent-scales longer than in
 the preceding form. East Mexico to Honduras. — **rhypidius** *R. & J.* Hindwing in both sexes with very
laodamas. large greenish white central area, which in the ♂ fills up the cell almost to the base, in the ♀ to the first
 quarter. Costa Rica. — **laodamas** *Fldr.* (6d) is the best-known form, which is very common in Bogotá-
 collections; it is known from the west coast, the Magdalena Valley and the Cordillera of Bogotá. The first
 spot on the band of the hindwing is very large and reaches almost to the base; it touches the cell, as do
 the next two or three spots. The ♀ is not known.

lycidas. **P. lycidas** *Cr.* (= *erymanthus* *Cr.*) (6d) is easy to recognise by the white stripe before the hind-
 margin on the upper surface of the hindwing; this stripe is shorter in the ♀ than in the ♂. — Guatemala
 to Bolivia and Pará. Appears not to vary geographically. There is only one form of the ♀ known. The ♂
 occurs commonly at the edges of water-courses. Like the allied species the butterflies first fly a few times
 round the places where they are going to alight to drink, as if they wished to make sure of the absence
 of enemies; but they are not easily disturbed when once they have begun to drink.

crassus. **P. crassus** *Cr.* (6d). A very long-winged species, distributed from Costa Rica to Rio de Janeiro.
lepidus. Forewing with white patches in and below the cell; hindwing with large white costal area, which in the ♂
 reaches to the base. In the ♂-f. **lepidus** *Fldr.* the white patches on the upper surface of the forewing
 are wanting. — The black-brown larva (probably variable in its ground-colour) has no spots. The thoracic
 hump of the pupa is very long and divided at the tip.

B. Fluted-Papilios.

Here belong the greatest part of the Swallowtail species. Although the forms have followed very
 different lines of development and often in their outward appearance have not preserved the slightest resem-
 blance to one another, yet this apparently heterogeneous mixture of species is distinguished by sharply
 marked characters from the other two divisions of the Swallowtails, namely the Aristolochia-Papilios and the
 Kite-Papilios. The segments of the scaleless antennae are somewhat narrowed at the base; the fine sensory
 hairs are almost equally distributed over the ventral surface or confined to two large, non-impressed lateral
 areas. The tarsi are likewise not scaled; the dorsal spines of the segments are separated from the ventral
 spines by a spineless, impressed lateral space. The abdominal margin of the hindwing in both sexes is
 curved downwards, forming a kind of groove; a scent-organ is wanting on the hindwing. The tibiae of
 the ♂ are never thickened nor covered with fine hairs. — The larva is either smooth, without humps, or
 the tubercles are hard and spiny, not fleshy. The third and fourth thoracic segments are enlarged, so that
 the larva appears thinner in front and behind. Many of the larvae bear on the thorax on both sides a
 sort of eye-spot and on the middle of the body a saddle-patch. Plants of very many families serve as
 food, partly herbs (Umbelliferae, Composites, etc.), but still more often the leaves of trees. — The pupa is
 wrinkled like leather and often resembles a piece of wood. The head is produced into two tubercles or is
 truncate, and the thorax bears a usually rather short horn. The wing-cases are expanded much less in
 mussel-shape than in the Aristolochia-Papilios, and the humps on the abdomen, if present at all, are very short.

The Fluted-Papilios occur in all tropical and temperate regions (New Zealand excepted), and extend
 northwards with one species as far as the arctic zone. They are therefore the most widely distributed
 division of the Swallowtails. In their habits they differ quite as much from one another as is their garb.
 Most species are good fliers, which if frightened hurry away in frantic haste. They almost all visit flowers,
 especially the ♂♂, and are fond of resting on damp sand or mud. Here their difference in character from
 the Aristolochia-Papilios becomes apparent, in that they do not crowd together in thick clusters, but rest
 singly round the outside of the crowd formed by Pierids and Kite-Papilios. Very many of the Fluted-
 Papilios wear the dress of other butterflies. In America Danais, Heliconids, Pierids, and especially

Aristolochia-Papilios serve as models. In some cases only the ♀, or one of the ♀-forms, is mimetic. Among the American Fluted-Papilios are found a number of powerfully built species with the costal margin of the forewing dentate. We find something similar in the ♂♂ of the Indo-Australian Pierid genus *Prioneris*, and in the Nymphalid genera *Charaxes*, *Eulepis*, *Euxanthoe* and *Palla*, which are all Old World insects. The dentition of the costal margin of these butterflies is evidently a phenomenon accompanying the strengthening of the margin, which is closely related to the acquisition of a strong flight.

Sexual dimorphism is very common among the Fluted-Papilios; as a rule one ♀-form resembles the ♂, whilst the other is mimetic. Sharply pronounced seasonal dimorphism is not observed among the American Fluted-Papilios, yet in the few North American forms which belong here, the butterflies which emerge from the hibernated pupae are generally smaller and more hairy than the summer brood, showing also slight differences in the markings. The trimorphism in both sexes of *P. polyxenes* and *P. bairdi* is very note-worthy.

Machaon-Group.

The species of the *machaon*-group have ringed larvae, which live on Umbelliferae, partly also on Artemisia.

P. polyxenes. Abdomen black, dotted with yellow. Palpi yellow. The posterior yellow spots of the discal band of the forewing remote from the cell, the discal band sometimes wanting. Geographically and individually very variable. The earlier stages very similar to those of *P. machaon*. The forms of North and Central America fly like *P. machaon* in cultivated districts, over meadows and fields covered with flowering fodder-plants, especially clover, at little distance from the ground. The South American forms only occur at considerable elevations. We have here the same phenomenon which we observe in Asia of *P. machaon*, which is likewise a high mountain species south of the Himalayas, in North-East India, Sikkim and Burma. — **americus** Koll. (= *sadulus* Luc.) occurs in three varieties. In the form **melasina** R. & J. *americus. melasina.* (8a) the yellow band on the wings is very much narrowed, sometimes reduced to a small spot, whilst in the true *americus* Koll. the band is broad, especially on the hindwing; the pale yellow area on the under-side of the hindwing not seldom reaches to the base. The black form lives especially in the Cauca Valley, Colombia, but also occurs elsewhere together with the ordinary form. Venezuela, Colombia, Ecuador and North Peru, occurring only at considerable heights, found up to about 3000 m. — **stabilis** R. & J., very *stabilis.* similar to the usual *americus* form, always with a broad yellow band, the last spot of the band of the forewing shorter than in *americus*, the band on the hindwing beneath sharply defined at the basal side. Costa Rica to Panama, common at a height of 1000 to 1300 m. — **asterius** Cr. (= *asterias* F.) is in some districts very variable, in others pretty constant. The ♂ is much more variable than the ♀. We distinguish three principal forms of the ♂, which are connected by intermediate stages and occur all three together in many districts. ♂-f. **asterius** Cr. has a macular band which traverses the extremity of the cell of the *asterius.* hindwing. Specimens with almost pure white spots on the upper surface are ab. **semialba** Ehrm. The ♂-f. *semialba.* **asterius** occurs from New England to South Mexico. The second variety is ♂-f. **curvifascia** Skinn. from *curvifascia.* Mexico and Guatemala; in this the band of the hindwing is placed outside the cell and is almost uniformly curved. The most striking form is the ♂-f. **ampliata** Mén. (= *asterioides* Reak.), in which the band is *ampliata.* broken up into small spots, which are often partly absent from the forewing. This black form is common in West Mexico, but also flies singly in East Mexico, and one specimen has been bred in Colorado. The ♀ of *asterius* is much less variable. A few striking aberrations of both sexes have been named: in ab. **calverleyi** Grote the submarginal spots are very strongly enlarged and merged into a broad band; in ab. *calverleyi.* **alunata** Skinn. & Aur. on the contrary the submarginal spots on the hindwing are very small and bluish. — *alunata.* **polyxenes** F. (8a). The ♀ resembles the ♂, the band of the hindwing is on the whole somewhat broader *polyxenes.* than in ♂-f. *asterius*. Cuba. — **brevicauda** Saund. (= *mediocauda* Eimer). Sexes similar to one another, *brevicauda.* wings broad and short, outer margin of the forewing somewhat rounded. Inhabits Newfoundland, Anticosti and the districts adjoining the lower course and the estuary of the St. Lawrence River; June to August: the larva on parsley and other Umbelliferae near the coast and the river.

P. bairdi Edw. Either similar to *P. machaon*, but the anal ocellus with black pupil, or similar to *P. polyxenes*, or standing between the two in its markings. These three forms, which occur together in Colorado, are: f. **oregonia** Edw. (= *brucei* Edw.) (8a), *machaon*-like, known from Colorado, Oregon, *oregonia.* Washington Territory, West Canada and British Columbia. The second form, which is known from Utah, Colorado and Arizona, is f. **hollandi** Edw.; the abdomen is *machaon*-like, whilst the wings resemble those *hollandi.* of the following form. In f. **bairdi** Edw. (= *utahensis* Streck.) (8a), which is found in Arizona, Colorado *bairdi.* and Utah, the black abdomen is spotted. The identity of the three forms has been established by breeding. Such non-seasonal trimorphism in both sexes is rare. The butterfly flies in Colorado together with *P. polyxenes asterius*, and in Oregon and further north with *P. zelicaon*, but the insects are independent of one another. Whilst the larvae of the allied species feed on Umbelliferae, those of *P. bairdi* live on a Composite (*Artemisia*); the larvae of all these butterflies are very similar to one another.

nitra. **P. nitra** *Edw.* (8b). Wings shorter than in *P. bairdi*; very similar to *f. bairdi*; perhaps only a northern subspecies. — Known from Montana and West Canada; in the mountains in June and July.

zelicaon. **P. zelicaon** *Luc.* (= *zolicaon* *Boisd.*) (8b). The yellow discal area behind the 2. median of the forewing extending close to the cell; underside of the abdomen black, with or without an indication of yellow lines. — On the west coast a common insect, descending into the lowlands. From Arizona northwards to Alaska and eastwards to Colorado. Found up to a height of 3000 m. The larvae on Umbelliferae.

coloro The ab. **coloro** *Wright* is founded on an old, dark yellow coloured specimen.

P. indra. Thorax above anteriorly with yellowish lateral stripes. Spots on the wings whitish yellow, much paler than in the allied species; the size of the spots rather variable. — A western mountain species, which is difficult to catch; it occurs up to a height of 3500 m, and by preference inhabits rocky land, where the butterfly suns itself on the rocks. It does not frequent flowers and is a shy, swift flier. No satisfactory observations of the earlier stages have been made. The larva according to *EDWARDS* lives on *Artemisia*. There are two subspecies. — The northern form with short tail is the true **indra** *Reak.* (8b); it occurs in Colorado, Nevada, Utah and northern California. — The form which flies in the mountains near the coast of South California at 600–1000 m height is **pergamus** *Edw.*; it is distinguished by its long tail.

aliaska. **P. machaon**. This Palaearctic species is represented in America by the subspecies **aliaska** *Scudd.* (= *joannisi* *Verity*) (8b). The black band on the hindwing is broader than in the geographically nearest subspecies *kamtschadalus*. *Aliaska* is rather common in July and August in Alaska, at the mouth of the River Yukon and on other rivers, as well as in the neighbourhood of lakes, probably everywhere in the lowlands where Umbelliferae grow. The insect is however still rare in European collections. Eastward *aliaska* occurs as far as Hudson's Bay.

Thoas-Group.

The following species of the *thoas*-group have all a spatulate tail. The larvae bear a saddle-spot before the middle and a large diffuse sidepatch on the last segments.

P. thoas. The spatulate tail has a yellow spot in the middle. The species occurs from Texas and the West Indian Islands southwards to Buenos Aires, but is wanting on the Lesser Antilles. It is everywhere common and flies in the open country, in gardens and plantations. *Thoas* is a very bold flier, which often mounts high in the air. The larva lives on Piperaceae and Citrus. — **melonius** *R. & J.* is the subspecies from Jamaica; it has no cell-spot on the upper surface of the forewing. The reddish yellow spots on the under surface of the hindwing are very large. — **oviedo** *Gundl.* (= *epithoas* *Oberth.*) occurs on Cuba. The upper surface of the forewing, and especially the under surface, are more extended yellow and have also a deeper tint than in the other subspecies. — **autocles** *R. & J.*, occurring from Texas to Nicaragua, has no cell-spot; the yellow areas are pale. — **nealces** *R. & J.* is distributed from Nicaragua to North-West Ecuador and eastward to Trinidad and the Lower Orinoco. The forewing has always a cell-spot: the yellow tint is somewhat deeper than in *autocles*, but less deep than in the next subspecies; very common in Bogotá-collections. — **thoas** *L.* comes from the Guianas and the Lower Amazon. Deep yellow; forewing with cell-spot, the first spot near the apex of the wing usually small. — **cinyras** *Mén.* is a large form, which inhabits the Middle and Lower Amazon and the eastern slopes of Ecuador, Peru and Bolivia; the submarginal spots of the forewing are almost always absent. — **brasiliensis** *R. & J.* (7a), from Brazil, Paraguay and North Argentina, is often still larger than *cinyras*; the cell-spot of the forewing is absent or small, the first spot near the apex of the wing is mostly large and produced into a point. — **thoantiades** *Burm.* occurs in Argentina, especially in the province of Buenos Aires. It is a small form, usually with narrow, pale yellow band.

homothoas. **P. homothoas** *R. & J.* (7c). Tail shorter and more rounded at the tip than in the *thoas*-forms from South America; no cell-spot on the forewing. Genitalia quite different from the organs of *P. thoas*; instead of the long anal clasper of *thoas* there is a short fork, the teeth of which are curved right and left; harpe broad, rounded. Orinoco, Colombia, Marguerita Island off the coast of Venezuela.

cresphontes. **P. cresphontes** *Cr.* (7a). Usually considered a slightly different variety of *P. thoas*. No cell-spot on the forewing; the fifth discal spot projecting further than the sixth. Claspers of the ♂ separate above, the anal hook quite short, the lower part of the anal segment likewise quite different from that of *P. thoas*; harpe broad, rounded. A common species in eastern North America, occurring as far as Costa Rica in the south and southern Canada in the north; but the insect is a wanderer, which is found only now and then in the northern districts. In the United States it does not extend westward beyond the Mississippi plain, except in the Southern States. Its true home is the region adjoining the Gulf of Mexico. It occurs also on Cuba.

P. paeon. Sexes similar, as in the preceding species. Tail without yellow spot at the tip, the marginal spot behind the tail large. The larva on *Pastinaca sativa* and probably other Umbelliferae, resembling bird-droppings; thorax strongly swollen: in paler specimens the markings, which resemble those of the *thoas* and *cresphontes* larvae, scarcely visible. The pupa, in which stage the species remains about three weeks, is of the same shape as in the previous species. — In **thrason** *Fldr.*, from Colombia and North Venezuela, the marginal spot behind the tail is very long, extending to about the third quarter of the tail. — **paeon** *Boisd.* (7c) is the southern form, in which the marginal spot only extends to the middle of the tail: the black marginal lines on the under surface of the hindwing broad, strongly curved between the veins. Ecuador, Peru and Bolivia; formerly (perhaps erroneously) recorded from Chile.

P. caiguanabus *Poey* (= *numicus* *Hopff.*) (8c). A species which has a peculiar appearance owing to the absence of the yellow discal bands and the enlargement of the submarginal spots. — Only on Cuba, rather rare, commoner in the eastern part of the island than in the western.

P. aristor *Godt.* (8d). From Haiti; the only known specimen (Godart's name-type, which was in the Paris Museum, seems to have been destroyed) is in the large collection of Mons. Charles Oberthür: it was found near Port au Prince. Forewing with two rows of yellow spots; the discal row curved, not extending to the hindmargin, the outer row complete; hindwing with a row of yellow spots. Underside of the forewing with a yellow spot in the cell.

P. aristodemus. Wings marked similarly to those of *P. thoas*; cell of the forewing beneath quite yellow; tail black above, beneath with a yellow patch in the middle. Cuba, Haiti and Porto Rico: two subspecies. — **temenes** *Godt.* (7c) is the form from Cuba; the yellow discal band is broad and the forewing has 5—7 submarginal spots. — In **aristodemus** *Esp.* (= *daphnis* *Gray*; *cresphontinus* *Kirby*), from Haiti and Porto Rico, the discal band on the forewing is narrow and the row of 4 submarginal spots is strongly curved.

P. andraemon. An almost straight yellow band from the apex of the forewing to the middle of the hindmargin of the hindwing, a transverse area in the cell of the forewing and a short costal band outside the cell. Hindwing strongly dentate; tail with spot in the middle. The larva lives upon Citrus and Ruta; the second and third segments have a pale transverse band and the olive-brown segments 5—7 are laterally spotted with white, the 10. and 11. segments also bear white spots. — **andraemon** *Hbn.* (8b), which occurs on Cuba, has no distinct submarginal spots on the upper surface of the forewing. — **bonhotei** *Sharpe* is the form from the Bahamas, with pale markings and distinct submarginal spots on the upper surface of the forewing. — **tailori** *R. & J.*, from Great Cayman, has no distinct cell-spot on the forewing.

P. machaonides *Esp.* (= *lycoraeus* *Godt.*) (9a) takes the place in Haiti of the preceding species, which is wanting there. The discal band of the forewing is interrupted, the posterior part contiguous with the cell-spot, forming an oblique band. Nothing is known as to the habits of this beautiful insect. The negro republics of St. Domingo and Haiti are as good as closed against the white collector.

P. thersites *F.* (9a) is similar to the well known *P. lycophron* *Hbn.* In the ♂ the yellow band on the forewing is very broad and the cell-spot very large. In the ♀ the forewing has a curved yellow band. — Jamaica. The larva like that of *P. lycophron*.

P. ornythion *Boisd.* (7b). Forewing without cell-spot; discal band narrow; forewing beneath with a row of narrow spots between the discal band and the submarginal spots. — Yucatan, West Mexico and Guatemala.

P. lycophron. Submarginal spots on the hindwing above and beneath large, hindwing beneath with a row of strongly curved reddish yellow crescents. The ♀ occurs in two forms in many districts; it is always unlike the ♂. The larva, which lives on Citrus, is mottled with brown; the yellow lateral spots are large. Mexico to Argentina and South Brazil; several subspecies; is said to occur also on St. Lucia. — In **pallas** *Gray* the ♂ has a discal band broken up into spots; the submarginal spots on the forewing are distinct. In the ♀ the first or the first two submarginal spots are wanting; tail short; hindwing with three rows of spots. Mexico to Costa Rica. — **hippomedon** *Fldr.* (= *theophron* *Fldr.*). A small form with rounded hindwing; submarginal spots on the hindwing small; tail short. ♀ not known. Colombia and North Venezuela. — **phanias** *R. & J.* Similar to the following subspecies; in the ♂ the band on the forewing interrupted by broad black veins; submarginal spots of the hindwing above and of the forewing beneath smaller. ♀ with strongly dentate hindwing; tail narrow, not spatulate; submarginal spots on the hindwing nearer to the margin than in the following form. East Ecuador to Bolivia and Goyaz. — **lycophron** *Hbn.* (= *astyalus* *Godt.*, *mentor* *Dalm.*) (8d) is the form from Brazil, Paraguay and Argentina, the commonest of all. In the ♂ the veins intersecting the bands of the forewing are narrowly black and the submarginal spots on the under surface usually very large. The ♀ in two forms: ♀-f. **oebalus** *Boisd.* is grey-yellow posteriorly on the forewing and from the base to the disc on the hindwing; ♀-f. **pirithous** *Boisd.* (8d) has a black-brown upper surface with a row of yellow submarginal spots.

P. androgeus. As in the preceding species the sexes are different and the ♀ occurs in many districts in two forms. Tail narrow, pointed. Hindwing above with narrow bluish submarginal crescents, beneath with a regular row of reddish yellow crescents between cell and outer margin. Larva on Citrus; similar to that of *P. lycophron*; as in that species the pupa has on the upperside of the abdomen two rows of small tubercles. The butterfly is common in the open country, in gardens and at the edges of woods.

epidaurus. West Indies and Mexico southwards to Paraguay and South Brazil. — **epidaurus** *Godm. & Salr.* occurs on Cuba, Haiti and St. Lucia and also inhabits Central America from Mexico to Panama. ♂: the yellow area very broad; ♀: forewing with indications of a yellow band outside the cell; the grey-blue scaling on the hindwing dense. — **androgeus** *Cr.* (♂ = *policaon Cr.*) (10a). ♂: the yellow area less pale than in the following subspecies. ♀ in two forms: ♀-f. **androgeus** *Cr.* (10a) has on the forewing two large yellow patches, sometimes also a small spot; in the ♀-f. **piranthus** *Cr.* these spots are wanting or are merely indicated, the metallic scaling of the hindwing is not dense and extends into the cell. From Colombia to

piranthus.

laodocus. Bolivia, Matto Grosso and Pará. — **laodocus** *F.* (10a) inhabits Brazil proper, southwards to Paraná. The yellow area of the ♂ is pale, the small spots placed before the extremity of the cell are smaller and often entirely wanting. Only one ♀-f. known; this is similar to the ♀-f. *androgeus* of the preceding subspecies, but the upper yellow spot is smaller than the second.

Glaucus-Group.

The following species of the *glaucus*-group, with the exception of *P. pilumnus*, have in the hindwing a broad, strongly asymmetrical cell. The abdomen is striped longitudinally, not spotted. On the forewing the marginal band is connected with the 5. transverse band by a costal hook-shaped spot, whilst on the tailed hindwing a band running along the hindmargin forms a large V with the median band. The larva has an eye-spot on each side of the 3. thoracic segment and on the 4. segment a black transverse dorsal line, which, however, is wanting in *pilumnus*. The eggs are laid singly on leaves. The larva spins on the upper side of a leaf a silk cushion on which it rests. The edges of the leaf are more or less bent together by the threads. — The species occur in North America and Mexico, and inhabit the open country.

P. glaucus. The subapical hook-mark of the forewing is yellow in the middle, black at the edges; hindwing beneath more or less orange proximally to the black postdiscal line. The ♀ occurs in two forms, with the exception of the northern districts. Larva polyphagous, especially frequent on Rosaceae, lime, birch, ash, etc., in the North one generation, in the Middle States two and in the South three generations. The butterfly is very common; it visits flowers, and is also fond of feeding on putrid or strongly smelling substances. The motion up and down is rather swift, and when the insect is frightened and takes to flight, it hurries away with violent flapping of the wings in an irregular zigzag course. Two geographical forms. —

canadensis. **canadensis** *R. & J.* is a small form with broad black hindmarginal band on the hindwing; the yellow submarginal spots on the under surface of the forewing form a continuous line. From Newfoundland to Alaska and southwards to New England. — **glaucus** *L.* (♂ = *turnus L.*, *antiochus L.*, *australis Mayn.*). The black abdominal margin of the hindwing narrower than the interspace between it and the cell; the 3. black band on the forewing on the whole shorter than in the northern form. The ♀ is dimorphic. Intermediate specimens

turnus. are rare. The ♀ resembling the ♂ is ♀-f. **turnus** *L.* (9b); in the second form the ground-colour is brown-black

glaucus. and the bands consequently stand out only very faintly: ♀-f. **glaucus** (9a). From southern New England

fletcheri. to Florida and the Mississippi Plain. ♂♂ with enlarged irregular black markings are the ab. **fletcheri** *Kemp.*

rutulus. **P. rutulus** *Luc.* (9b). Forewing more pointed than in *glaucus*, the hook-mark much less scaled with yellow; hindwing without orange spot proximally to the black postdiscal line. Harpe of the ♂ with

ammoni. simple dorsal hook and the apex of the harpe dorsally to the apical spine not rounded. ab. **ammoni**

arizonensis. *Behrens* is founded upon dark yellow specimens (turned yellow?) from Nevada, and ab. **arizonensis** *Ede.* refers to specimens with broad black bands. — The larva lives upon willow, it is very similar to that of *glaucus*, but the thoracic spot is more oblong. The insect is an inhabitant of the west side of the continent, where it occurs from British Columbia to Arizona and Colorado. It is there fully as common as *glaucus* in the east and is chiefly found at the lower levels, although it also occurs in the mountains.

daunus. **P. daunus** *Boisd.* (= *multicaudata Kirby*) (9c). An extremely variable species both in the extent of the black bands and in individual size. Hindwing more strongly dentate than in the preceding species. The tooth behind the tail nearly always prolonged to a short pointed tail. The hook-mark on the forewing is always scaled with yellow along the centre, the bands are narrower than in *rutulus*, the 4. black band of the forewing is narrower than the apical yellow cell-space. Southern specimens are on the whole larger than northern ones. — Larva on Rosaceae, very similar to that of *glaucus*. The insect occurs from British Columbia and Alberta southwards to Guatemala; it is a species of the mountainous and prairie-like districts, which speeds along in swift, untiring flight, without stopping at flowers.

eurymedon. **P. eurymedon** *Luc.* (= *lewisi Kirby*, *arizonensis Wright*) (9c). Ground-colour paler than in the allied forms, the black bands broad; the hook-mark on the forewing not filled up with yellowish white

either above or beneath. Dorsal hook of the harpe of the ♂ shorter than in the allied species. Specimens occur sometimes in high mountains in which the marginal band of the forewing in the middle is about as broad as the yellowish white discal area, they are f. mont. **albanus** *Fldr.* — Larva on *Rhamnus californica*: *albanus*. the 3. and 4. segment above with small ring-spot, the black and yellow transverse dorsal line posteriorly on the 4. segment rather broad. A common mountain species, distributed from British Columbia to Colorado. The butterfly visits flowers, especially thistles and mint, and frequently drinks at puddles in large numbers. Its flight is swift and agile.

P. alexiaries. A broad-banded Mexican butterfly. The distal margin of the forewing is straight or very feebly concave; the hook-mark on the underside centred with yellow and this yellowish scaling continuous with the grey or yellowish line situated on the black postdiscal band. On the disc of the hindwing beneath more or less large orange-coloured patches. Early stages not known. Eastern Mexico: two subspecies. — **garcia** *R. & J.* (9b). Yellowish apical cell-area about as broad as the black band placed at its distal side. The black marginal band not broader in the middle than the yellow discal band; the yellow submarginal spots on the under surface of the hindwing narrow, more or less distinctly separated from one another. Monterey, province of Nuevo Leon. — **alexiaries** *Hopfl.* The yellow parts more or less dusted over with black, the black bands broader than in *garcia*, the posterior yellow submarginal spots are wanting on the upper surface of the forewing, whilst the submarginal spots on the under surface form a rather broad continuous band. Cuesta de Misantla, in Vera Cruz. *garcia*. *alexiaries*.

P. pilumnus *Boisd.* (9c). A less specialised form than the preceding ones. Cell of the hindwing almost symmetrical, tibiae and tarsi pale greenish. Hindwing above with 2 sharply defined orange spots: the proximal arm of the large V of the hindwing on the under surface divided longitudinally by a grey line. — The larva recalls that of *troilus*. The insect occurs in the open, high-lying Savannas of Arizona and Mexico southwards to Guatemala. *pilumnus*.

The two following species, *troilus* and *palamedes*, like the preceding forms, are Nearctic and form the transition to the mimetic *anchisiades*-group, which they approach rather closely in the early stages and in structure.

P. troilus. Black; thorax and abdomen with small yellowish spots; both wings with a row of submarginal spots, those on the forewing smaller in the ♀ than in the ♂; hindwing with bluish grey-green discal area. On the under surface the hindwing has a discal and a submarginal row of orange-coloured spots and distally to the discal row large metallic blue spots. The larva has a large eye-spot on each side of the 3. thoracic segment and large blind spots on the 4. It lives on the upper side of a leaf in a tube which is formed by the edge of the leaf being so strongly bent over to the middle rib that it comes to lie close against the upper surface. It is mostly found on sassafras and benzoin, Lauraceae, but also lives on other plants, as Magnolia, Prunus, Pirus, etc. Hibernates as pupa. Two broods. The butterfly usually hovers only a few feet above the ground, flying nimbly in quest of the flowers on which it feeds. Canada to Florida and Texas. — In **troilus** *L.* (= *ilioneus* *Abb. & Smith*) (8c) the submarginal spots on the under-side of the hindwing are bluish grey-green. Canada to Georgia and Texas, westward as far as the foot of the Rocky Mountains. In ab. **radiatus** *Streck.* the submarginal spots of the hindwing on the upperside are enlarged to longitudinal stripes. Specimens also occur in which the submarginal spots of both wings extend to the outer margin. — **texanus** *Ehrm.* has on both wings larger submarginal spots than the preceding species; many specimens have a pale subbasal band on the under surface. Florida; Texas (?). *troilus*. *radiatus*. *texanus*.

P. palamedes. Antenna brown; tibiae and tarsi green; abdomen striped with yellow. Markings on the underside of the wings pale yellow; 2 rows of spots on the forewing besides the marginal spots, the discal row doubled towards the costa: on the hindwing a discal band and a row of submarginal spots, and in addition, especially in the ♀, blue spots are present outside the discal band. On the under surface the hindwing has a narrow subbasal band and the discal band is dentate and more or less orange like the submarginal spots. The larva is very similar to that of *troilus* and has the same habits. On Magnolia. The butterfly is common in Florida in the spring. Distributed from Virginia southwards as far as North-East Mexico. The ♀ is more brownish black than the ♂. — **palamedes** *Drury* (= *chaleas* *F.*, *chaleus* *F.*, *flavo-maculatus* *Goeze*). The discal spots of the forewing are large, the cell has nearly always a spot. Virginia to South Florida and Texas, yet also found even in Nebraska. — **leontis** *R. & J.* (8c). A small form with reduced discal spots; forewing without cell-spot on the upperside or with only a very narrow streak. Monterey, province of Nuevo Leon, Mexico. (On pl. 8 the name is erroneously printed *leontia*.) *palamedes*. *leontis*.

Anchisiades-Group.

In the species of the *anchisiades*-group the pronotum and thorax are at least partly spotted with red or yellow-red. The abdomen is black and has no light markings except a basal lateral spot and streak. The cell of the forewing beneath is not streaked with yellow and the hindwing has no blue spots. The larvae, so far as is

known, are marmorated; the light colour forms before the middle, especially laterally, a large irregular spot; on each side a subdorsal row of tubercles. The larvae are shiny and superficially resemble those of Tenthredinidae; they rest in larger numbers on leaves or the trunk and are mostly found on Citrus. Pupa resembling a short broken-off twig; the thoracic horn not long.

P. hyppason *Cr.* (= *hyppason Esp.*) (10b, c). Tailless. Pronotum spotted with red. Hindwing beneath with red basal spot behind the cell. Subcostal of the hindwing much more proximal than the *hyppason*. 2. median. Sexes different from one another, each variable in itself. ♂-f. **hyppason** *Cr.* (= *hyppasonides ptilion. Girard-Smith*) has a broad band on the forewing, mostly abbreviated. In ♂-f. **ptilion** *H. & J.* the band of the forewing is narrow and placed farther from the cell. The ♀ occurs likewise in 2 principal forms: ♀-f. *amosis*. **amosis** *Cr.* has a black forewing, on which scarcely a trace of white discal spots is visible. In ♀-f. *paraensis*. **paraensis** *Bates*, on the contrary, the forewing has one or several white or yellowish white spots. These forms occur together, though not everywhere. — The Guianas to Pará, the Amazon upwards to Peru and southwards to South-East Bolivia; not known from Brazil proper, Ecuador, Venezuela and Colombia. The butterfly is found at the edges of swampy woods and has a swift flight.

P. pelaus. With spatulate tail. Sexes similar, but the markings in the ♀ somewhat enlarged and on the hindwing more numerous than in the ♂. Black, forewing with oblique white band from the costa to the anal angle; hindwing with complete (♀) or incomplete (♂) row of pale red submarginal spots; beneath there are usually also small discal spots present, which sometimes in the ♀ also occur above. West *pelaus*. **pelaus** *F.* (= *ornofagus Weidem.*, *peleus Gmel.*) (7b) has a proportionately broad white band on the forewing, which above, at least in the ♀, also enters the extremity of the cell. Jamaica and Cuba; *imerius*. perhaps the specimens from Porto Rico also belong here. — In **imerius** *Godt.* (= *augias Mén.*) the band of the forewing is narrower anteriorly, on the other hand its last spot is on the whole broader than in the preceding form, and the spots on the hindwing are smaller. Haiti.

oxynius. **P. oxynius** *Hbn.* (= *augustus Boisd.*) (10b). Similar to *pelaus*, but the band of the forewing only indicated; the marginal spots of both wings large. — Only known from Cuba. Larva on *Xanthoxylum*, gregarious by day, resting on the trunk and branches.

epenetus. **P. epenetus** *Hew.* (10b). Tailless; the ♀ paler than the ♂; forewing without spots except at the margin; hindwing with large yellowish white marginal spots and in the ♀ usually also some small discal spots. — From Western Ecuador, not known from the east side of the Andes. HAENSCH found the larvae in June in large numbers on Citrus.

chiansiades. **P. chiansiades** *Westw.* (= *chinsiades Kirby*) (10d). On the upper surface of the forewing before the hindmargin a large yellowish white spot; on the hindwing posteriorly some red discal and submarginal spots, the spots of the two rows separated from one another; the tooth of the 3. radial prolonged into a short pointed tail. The ♀ and the earlier stages not known. — Eastern slopes of the Andes of Ecuador and Peru, likewise on the Upper Amazon.

pharnaces. **P. pharnaces** *Doubl.* (= *phanostratus Godm. & Salv.*, *polycharmus id.*) (10c). More or less distinctly tailed, hindwing with two separated rows of red spots, the proximal spots in the ♂ often very small. — Mexico, distributed from the Atlantic to the Pacific.

erostratus. **P. erostratus** *Westw.* (= *herostratus Fldr.*, ♀ = *rhetus Gray*) (10c). Like the preceding species, but in the ♂ the spots on the upper surface of the hindwing yellowish white. In the ♀ the spots red also above, larger than in the ♂ of *pharnaces*, the marginal spots of both wings also somewhat larger than in the foregoing species. Tail long and narrow. — Guerrero in West Mexico (where *pharnaces* also occurs), Guatemala and British Honduras. Commonest in hilly country at a height of about 5000 ft.

rogeri. **P. rogeri** *Boisd.* Forewing lighter in colour from the apex of the cell outwards, the dark basal area rounded distally; hindwing with suggestion of a small tail; some red spots on the disc, in two separate rows, in the ♂ the proximal spots very small, usually only indicated; in the ♀ all the spots larger than in the ♂. — Larva not known. Yucatan and British Honduras.

P. anchisiades. A widely distributed variable species. Hindwing posteriorly somewhat prolonged, therefore more or less triangular; the tail is wanting or is only somewhat longer than the other marginal teeth, yet in the ♀ sometimes as long and pointed as in the following species. The red spots of both the rows of the hindwing on the underside partly contiguous, or at least two pairs placed quite close together. Larva on Citrus, often resting together in hundreds on the stems. A very common insect, which is fond of drinking at moist places on the banks of rivers; not a forest species. — **idaeus** *F.* (= *pandion Fldr.*, *pandonius Stgr.*). Forewing usually with a distinct white spot at the end of the cell above and beneath or only beneath. Central America, from Mexico to Panama. — **anchisiades** *Esp.* (= *anchises L. partim*, *theramenes Fldr.*, *pompeius Kirby*) (10d). Very variable. Forewing with two white spots posteriorly of

the 1. median vein, either on both sides or only beneath, on the underside also a spot before the 1. median, rarely present above, and sometimes one before the 3. radial. In other specimens the white spots are wanting above: the forewing is dark from the base to the apex of the cell and then paler, and has a row of white spots beneath. From Colombia to Pará and Bolivia. — **capys** *Hbn.* (= *evander* *Godt.*) (10c), *capys*. Forewing without white spots on the upperside; the disc paler, the dark proximal area rounded; on the underside a row of white spots, one of which is placed in the cell. East Bolivia, North Argentina, Paraguay and Brazil.

P. isidorus. Forewing on the under surface either without white cell-spot, or the spot small, not extending transversely across the cell. Hindwing posteriorly shorter than in *anchisiades*, the tail short, narrow; the last submarginal spot more distal than the large spot placed before it. The harpe of the ♂ not dentate. Larva not known. Panama to Bolivia; a species of the Andes. — **chironis** *R. & J.* Fore- *chironis*. wing above with 2 white spots between the 2. radial and 2. median and a small cell-spot; the spots beneath much larger, the spot between the 3. radial and 1. median the largest. Chiriqui. — **brises** *R. & J.* Fore- *brises*. wing above without spots, beneath with 2 or 3 spots, but without cell-spot. In Bogotá-collections, probably from the Magdalena and Cauca Valleys. — **flavescens** *Oberth.* The white spots on the underside of the *flavescens*. forewing reduced. The spot placed between the 2. and 3. radial of the hindwing usually white above or beneath or on both sides. East side of the Andes of Colombia, Ecuador and North Peru. — **isidorus** *Doubl.* *isidorus*. (10d). The white patch on the under surface of the forewing usually enters the cell and is often also indicated above; the red spots of the hindwing on the whole larger than in red-spotted specimens of *flavescens*, the two spots placed between the 2. radial and 2. median separated also on the upper surface. Eastern slopes of the Andes of Bolivia and Peru, northwards to Huánuco.

P. rhodostictus. Differs from *isidorus* chiefly in that the white cell-spot of the forewing at least beneath extends across the cell, the spots on the upper surface of the hindwing are merged in pairs into 3 or more rarely 2 large patches, and the harpe of the ♂ is almost symmetrical. Costa Rica to Ecuador. Larva not known. — **rhodostictus** *Bthr. & Druce* (10d), from Costa Rica and Chiriqui, has a *rhodostictus*. narrow cell-spot and the discal spot placed before the 3. radial is the largest or the most clearly developed. — **pacificus** *R. & J.* The discal spot between the 3. radial and 1. median is larger than the preceding one; *pacificus*. cell-spot large. West Colombia and West Ecuador. — **nymphius** *R. & J.* Forewing on the upper surface *nymphius*. without cell-spot, the spot between the 3. radial and 1. median on the under surface larger than the preceding spot. Central and East Colombia, not rare in Bogotá-collections. The spots on the hindwing are sometimes whitish.

Torquatus-Group.

In the species of the *torquatus*-group the palpus is yellow; the thorax is likewise yellow or at least spotted with yellow and the abdomen has at least a yellow lateral line. Both sexes are tailed, but the tail in the ♀ is sometimes short and pointed. In colour the ♂♂ and ♀♀ are always different; on the whole the ♀♀ are more black, the ♂♂ more yellow. The larvae are similar in colour to bird-droppings and bear 4 rows of rather long tubercles. The thoracic hump of the pupa is large.

P. himeros. Both wings with yellow band, which is broader in the ♂ than in the ♀; tail with yellow apical spot; submarginal spots of the hindwing in the ♂ yellow, in the ♀ red except the 2 anterior ones. Brazil; a rather rare species. — **baia** *R. & J.* The yellow markings reduced or narrowed. Bahia. — *baia*. **himeros** *Hopff.* (= *mentor* *Boisd.*, *herodotus* *Oberth.*). The yellow band on the forewing is contiguous to *himeros*. the cell and is broader than the black marginal area. Minas Geraës; Rio de Janeiro.

P. lamarchei *Stgr.* (11a). Only the ♂ known. The yellow band narrower than in *himeros*, forewing *lamarchei*. without yellow spot distally of the anterior angle of the cell; hindwing very strongly dentate, tail without yellow spot at the tip. Harpe short and rounded, whilst in *himeros* it is long and pointed. — In Northern Argentina and Bolivia, not rare.

P. hectorides *Esp.* (= *torquatinus* *Esp.*, *pandrosus* *Godt.*, *chirodamas* *Hbn.*) (11a). In the ♂ the band is still narrower than in *lamarchei*. Hindwing with red spots on the disc. In the ♀ the band is absent or is white; on the forewing it is curved anteriorly towards the costa and on the hindwing does not extend to the abdominal margin; the submarginal spots of the hindwing are red and narrow. The ♀ occurs in three principal forms: ♀-f. **hectorides** *Esp.* (= *mecentius* *Doubl.*, *argentus* *Gray*) (11a) has a white band on *hectorides*. both wings; in ♀-f. **catamelas** *R. & J.* the band is developed on the hindwing, but on the forewing merely *catamelas*. indicated; in ♀-f. **melania** *Oberth.* it is slightly indicated on both wings or entirely absent. These forms *melania*. occur together. — Larva on Citrus and Piperaceae, resting gregariously on the upperside of leaves. The butterfly is common. It is a swift flier, which is found especially at the edges of woods and in the neighbourhood of thickets. Brazil and Paraguay.

P. garleppi. ♂ similar to *torquatus*, but the yellow band broader and the marginal tooth of the 1. median of the hindwing longer; 2 or 3 small spots composed of yellowish and bluish scales placed before the red anal spot of the hindwing; on the underside the posterior discal spot placed at the 2. median is very small and bluish. The anal tergite is long and slender; harpe produced into a long point and furnished with a long pointed process at the ventral margin. The ♀ is not known. East Bolivia, East Peru and the Upper Amazon are the home of the insect. Two subspecies. — **garleppi** *Stgr.* Band of the forewing not interrupted. Bolivia. — **interruptus** *Stgr.* Band of the forewing interrupted. Upper Amazon and East Peru.

P. torquatus. ♂: the band of the forewing is interrupted between the 2. and 3. radial, rarely there is a yellow spot almost filling up the gap; on the under surface of the hindwing a row of red discal spots, of which the last is placed proximally to the last submarginal spot. The ♀ very different from the ♂, resembling certain *Aristolochia-Papilios* which occur together with it; wings brown-black, with or without white patches on the forewing; hindwing above with two rows of red spots, the proximal row incomplete, some of the spots merged together in pairs into 2 or 3 large patches. The anal tergite of the ♂ spatulate; the harpe broad, denticulate. Larva shiny, as if polished (which is also the case in all the allied species), mottled with light colour, with irregular pale patch before the middle; the colour of bird-droppings. The butterfly is found in forests and in their neighbourhood; the ♀ is a true woodland species, like the *Aristolochia-Papilios* whose dress it wears, whilst the ♂♂ disport themselves more in open, sunny localities.

tolus. Mexico to Brazil, not known from the temperate part of South America (South Brazil, Argentina). — **tolus** *Godm. & Salv.* ♂: band of the forewing narrow, the anterior spot long, the 2. short. ♀: forewing without white discal spots; hindwing with 2 separated rows of red spots. Tail in both sexes long and spatulate.

tolmides. Mexico, apparently rare. — **tolmides** *Godm. & Salv.* ♂: band broader than in *tolus*, tail narrower, no spots, or only very small ones, before the upper angle of the cell of the forewing. ♀ not known. Chiriqui and

orchamus. Sevilla Island; likewise rare in collections. — **orchamus** *Boisd.* ♂: the spots before the upper angle of the cell of the forewing small, the first long spot of the yellow band as long as the 2., or somewhat longer, the submarginal spots of the hindwing usually very distinct. ♀ with a white spot placed across the cell of the forewing and another spot before the 1. median, as well as usually also a spot before the 3. radial and an indistinct spot behind the 1. median; 4—6 large red spots on the hindwing, cell with spot, tail short,

leptalea. non-spatulate. Colombia; North Venezuela. — **leptalea** *R. & J.* ♂: yellow band of the forewing narrower than the black marginal area, narrower than in all the other forms of this species; the spots before the apex of the cell small; the submarginal spots of the hindwing distinct, the apex of the cell on the under surface black as far as the base of the 1. median; tail spatulate. ♀ similar to that of *orchamus*, the white

torquatus. spot between the 2. and 3. spot of the forewing and the cell-spot smaller. West Ecuador. — **torquatus** *Cr.* (= *pelaus* *F.*) (11b). ♂: the spots before the apex of the cell of the forewing mostly larger than in the other forms, the two subapical spots of the band broad, the 1. shorter than the 2., the band at least half as broad again as the black submarginal area; the submarginal spots of the hindwing usually strongly darkened by black scaling. The ♀ very variable; the tail always slender, commonly short; 5 principal

theras. forms: ♀-f. **theras** *R. & J.*, forewing with cell-spot, which however does not extend across the cell, and one or more spots on the disc; ♀-f. **caudius** *Hbn.* has no cell-spot, but several discal spots, of which the one

patros. placed between the 1. and 2. median is the largest; ♀-f. **patros** *Gray* (11b) has no white spots on the forewing, the patches on the hindwing are red; ♀-f. **flavida** *Oberth.* (= *flava* *Haase*) resembles *patros*, but

cleolas. the patches on the hindwing are yellow-white; ♀-f. **cleolas** *R. & J.* has no spots on the forewing, but on its under surface a yellowish white submarginal band. These different forms of the ♀ occur only partly together, the first 4 are known from the Upper Amazon, but the 5. form, which we have from Bolivia, may also be found there. East and South Venezuela, the Guianas, the Amazons and the eastern slopes of

polybius. the Andes of Ecuador, Peru and Bolivia. — **polybius** *Swains.* (♀ = *tros* *Hbn.*, *trojanus* *Boisd.*) (11b) inhabits Brazil, Matto Grosso and Paraguay. In the ♂ the spots before the apex of the cell of the forewing are small and the submarginal spots on the underside rather large; on the hindwing beneath the cell is entirely or almost entirely yellow; the tail broad. The ♀ occurs only in one form: forewing with spot in the cell and a large patch between the 1. and 2. median; tail spatulate, with rounded tip.

P. tasso *Stgr.* (11a). ♂: band of the forewing abbreviated, the subapical part wanting. ♀ with broad white band, which begins on the forewing at the 3. radial and extends to the hindmargin of the hindwing; the cell of the forewing beneath with a few yellow streaks; the tail non-spatulate. — Only a few old specimens known, which probably came from Brazil.

P. peleides *Esp.* Perhaps an artefact; only known from JABLONSKY's figure; is it perhaps a West Indian representative of *torquatus* not rediscovered? ♂: forewing with a yellow macular band of almost uniform breadth, curved forward to the costa; hindwing with yellow submarginal spots, the last of the row red, as well as one placed proximally to it at the hindmargin; tail spatulate.

Zagreus-Group.

The remaining Fluted-Papilios are powerfully built insects with strong venation in the forewing. The frons is either quite black or bears a yellow mesial line, never a yellow lateral streak along the eye. In the mimetic *zagreus*-group the antennae are long, yellow, with thin club; the frons has a yellow mesial stripe, the breast is diagonally streaked with yellow, the abdomen is for the most part yellow, the costal margin of the forewing is not dentate, the cell of the forewing is broad and the hindwing is rounded, without a tail. The species resemble *Tithorea* species, but are much more powerfully built. The earlier stages are unknown. The ♀♀ are very rare in collections; they are similar to the ♂♂.

P. zagreus *Doubl.* (11c). The spots of the forewing orange, the marginal ones yellow; hindwing *zagreus*. orange, a marginal band enclosing a yellow submarginal spot, a basal subcostal area, a patch in the extremity of the cell, as well as several spots on the disc, black. — Venezuela and Colombia, southwards to Bolivia, descending on the Amazon as far as Ega; varying individually, but not distinctly geographically.

P. ascolius. Hindwing without black spots in the cell and on the disc. Chiriqui to West Ecuador, occurring in Colombia together with the preceding species. Geographically and individually variable. — **zalates** *Godm. & Salv.* is the most northern form. The cell area of the forewing is dusted with black, the *zalates*. subapical cell-spot is narrow, the discal spots are short, the marginal area of the hindwing narrower than in the other forms and the hindwing beneath deeper orange. Republic of Panama, found in various localities. — **daguanus** *R. & J.* The cell-spot of the forewing as in *zalates*, the discal spots on the contrary as *daguanus*. in *ascolius*, the discal spot between the 1. and 2. radial much shorter than the one placed behind it; hindwing pale, much less orange than in *ascolius*, the black basal streak broad, entering the cell, behind this streak a large black spot on the disc. West Colombia, at the Rio Dagua. — **ascolius** *Fldr.* (11c). The *ascolius*. basal area of the cell of the forewing always pure pale yellow, between the 3. radial and 1. median two spots touching the cell; cell of the hindwing and the adjoining parts of the disc orange. Magdalena Valley and Cordillera of Bogotá. — **rosenbergi** *Druce*. The subapical cell-spot of the forewing large, the discal *rosenbergi*. spot between the 1. and 2. radial usually small, sometimes absent, rarely large, the following discal spots on the whole larger than in the preceding forms, whilst the posterior submarginal spots are smaller; the hindwing mostly very pale, yet sometimes more orange than the palest specimens of *ascolius*. West Ecuador, found by ROSENBERG at a height of 1000 to 3500 ft.

P. bachus. The orange area of the hindwing of the preceding species is here only represented by a narrow variable band; however, the veins are often more or less yellowish on the underside. The ♀ is not known. Colombia to Bolivia. Two subspecies. — **bachus** *Fldr.* (11c). The yellow spots of the fore- *bachus*. wing above and beneath quite pale, only the proximal cell-spot and the posterior discal spots somewhat orange. Colombia; found by Dr. BÜRGER at the beginning of the rainy season in the Cordillera of Bogotá; rare in collections. — **chrysomelus** *R. & J.* The forewing orange above and beneath from the base to the *chrysomelus*. disc, at the costal margin more or less pale yellow. Peru and Bolivia, not rare. From Ecuador no specimen of *bachus* has become known to us.

Scamander-Group.

P. hellanichus, *scamander*, *birchalli* and *xanthopleura* belong to the *scamander*-group. The frons is black and the otherwise black palpus has a white dot. The costal margin of the forewing is feebly dentate, especially near the base, but the dentition only becomes distinct if the margin is denuded. Only the larva of *scamander* is known; when full-grown it is black-brown beneath, green elsewhere, and bears a transverse band before and behind on the 3. thoracic segment, as well as two diagonal bands on the abdomen, which are usually united on the back, forming an X-shaped mark. The young larva on the contrary is brown and has on the middle segment and on each of the posterior ones a large grey patch. The pupa is green or brown-grey; it is fastened low down on the stem, usually close to the ground. On Magnolia, Canella and Citrus.

P. hellanichus *Hew.* (11d). The yellow spots on the upper surface of the wings are large. The *hellanichus*. insect reminds one superficially of *machaon*, with which, however, it is not closely allied. The markings of the under surface as well as the structure prove that *hellanichus* is the southern representative of *scamander*. The cell has also on the upper surface a yellow spot, which on the forewing is sometimes very small, on the hindwing always large. The spots of the discal band have almost all reddish tips. ♀ quite similar to the ♂. — Uruguay and the adjoining parts of Argentina and Brazil, especially in the neighbourhood of the river and on the islands in the estuary of the La Plata.

P. scamander. Cell of the forewing without spot, that of the hindwing sometimes with a small spot; a pale yellow curved discal band, broken up into spots, on both wings. ♂ and ♀ very similar. Larvae and pupae described above. Brazil, common in hilly country, though not everywhere. Three geographical forms, which completely intergrade. — **grayi** *Boisd.* The submarginal macular band of the forewing evenly *grayi*. curved, the discal band broadest posteriorly; the red discal spots on the under surface of the hindwing separated from the discal band. Bahia to Paraná. — **eurymander** *Hopff.* The first 2 or 3 submarginal *eurymander*.

spots of the forewing more proximal than the other spots of this row, the submarginal spots of the hindwing partly pale yellow; the basal area of the hindwing beneath pale, often partly yellowish, the red discal spots small or absent. Santa Catarina and the adjoining districts of Rio Grande do Sul. — **scamander** Boisd. (11d). Discal band of the upper surface more yellow; under surface of the hindwing pale yellow, with black veins and without red discal spots. Abdomen laterally pale yellow. Rio Grande do Sul.

P. birchalli. ♂: body black, claspers usually with pale yellow spot. Forewing above with 2 rows of spots before the margin; the anterior spots of the proximal row more or less indistinct; hindwing with broad discal band and a row of submarginal spots; the markings for the most part greenish; tooth of the 3. radial only a little more projecting than the other marginal teeth. Beneath the forewing has a cell-spot, an oblique row of discal spots and a row of submarginal spots abbreviated anteriorly; on the hindwing is a discal and a submarginal row of red spots, the middle discal spots small, the last one large and yellowish white. In the ♀ the markings of the upperside are more bluish and the discal band of the hindwing is very broad. Panama and Colombia; according to Druce it occurs also in North Argentina, which appears to us doubtful. — **godmani** R. & J. The last spots of the discal band of the hindwing above indistinct and the band broader in the middle than the black marginal area. Panama: Chiriqui and Bugaba. — **birchalli** Hew. (11d). The discal band of the hindwing above narrower than in *godmani* and its two last spots distinct. Colombia: Magdalena and Cauca Valleys.

P. xanthopleura Godm. & Salv. (12c). Sides of the abdomen yellow; under surface of the hindwing without discal band, the red submarginal spots large. The ♀ in two forms: ♀-f. **xanthopleura** is similar to the ♂, whilst ♀-f. **diaphora** Stgr. has a large pale yellow area on the upperside of the forewing. — Upper Amazon.

Homerus-Group.

All the following Fluted-Papilios are distinguished by a strongly dentate costal margin of the forewing in the ♂, which is weaker in the ♀. The black abdomen is never spotted, but the underside of it in some forms is yellowish olive-brown. The antennae are short and the frons is broad. Like the preceding species they are forest insects, which occur in the mountains, especially at medium heights.

P. victorinus. A Central American species, occurring from Mexico to Costa Rica. ♂: two rows of pale yellow spots on the upper surface between two rows of bluish grey spots, which are distinct especially on the hindwing. Hindwing beneath with a row of red, black-edged discal spots and a row of crescent-shaped submarginal spots; tooth of the 3. radial only very little prolonged. Larva green above, grey beneath, anteriorly with two transverse grey, spotted, dorsal bands; abdomen laterally grey, dorsally with two angle-shaped spots. Two broods. — **morelius** R. & J. Discal spots of the forewing small or absent, no cell-spot on the underside. West Mexico. — **victorinus** Doubl. (11d). ♂: discal row of the forewing consisting of at least 3 spots; usually a row of bluish grey postdiscal spots present; discal spots of the under surface of the hindwing larger than the submarginal spots. The ♀ in two forms: ♀-f. **victorinus** Doubl. (= *helleri* Fldr.) is similar to the ♂, but the spots of the upper surface, especially of the hindwing, are mostly larger; in ♀-f. **amphissus** Hopff. the hindwing has a bluish or greenish discal band, much broadened posteriorly. East Mexico to Nicaragua. — **vulneratus** Bthr. The discal spots of the upper surface of both wings larger than in the two preceding subspecies; hindwing without bluish spots distally to the discal row. Costa Rica, only one ♂ known (in coll. F. DUCANE GODMAN).

P. cephalus Godm. & Salv. ♂: tailed, two rows of spots on the upperside of the forewing, the submarginal row uniformly curved. Underside of the hindwing with bluish crescents distally to the discal spots. — Chiriqui, one ♂ in coll. STAUDINGER; perhaps only a tailed specimen of *P. cleotas archytas* (the genitalia should be compared!).

P. cleotas. Forewing above with a submarginal row of spots, curving in front towards the costa, and an oblique discal row of larger patches posterior to the lower angle of the cell; hindwing with discal band and submarginal spots. Under surface of the hindwing with a row of red discal spots, which are proximally more or less yellow, the last spot always pale yellow. The ♀ in two forms, one similar to the ♂, the other with broad bluish or greenish band, diffuse proximally. Distributed from Costa Rica to South Brazil, but not known from Bolivia to Ecuador, nor from the Guianas, the Orinoco or the Amazon, being replaced in these districts by *P. aristeus*. — **archytas** Hopff. (♂ = *laetitia* Bthr.). ♂: the cell-spot and the middle discal spots of the forewing smaller than in the next form. In the dimorphic ♀, ♀-f. **archytas** Hopff. is similar to the ♂, whilst ♀-f. **panthias** R. & J. has bluish or greenish markings on the upperside. Costa Rica: Panama: Brava Island on the west coast of Panama. — **phaeton** Lucas (= *phaëton* Doubl.) (13a) inhabits Colombia. ♂: the markings on the upper surface very variable. The cell-spot of the forewing usually more oblique than in *archytas*, sometimes absent (ab. **clearchus** Fldr.), and the anterior submarginal spots larger than the posterior ones; tail distinct; harpe dentate at the dorsal margin, with a strong apical hook curved inwards, the dorsal prong of the fork short.

The ♀-f. **phaeton** *Luc.* is similar to the ♂. The second form, ♀-f. **syndemis** *nor.*, has a broad bluish band *syndemis*. on the hindwing; the discal spots of the upper surface of the forewing are bluish, the middle ones only indicated, those of the under surface are only represented by a few indistinct little spots; hindwing above with distally convex bluish crescents outside of the discal band; discal band of the underside reduced, consisting of small, black-edged red spots; tail long; one specimen, from Bogotá, in the Tling Museum.

coroebus *Fldr.* ♂: the cell-spot of the upper surface of the forewing is absent, or it is more or less distinct *coroebus*. but diffuse (ab. **philocleon** *Fldr.*); the discal spot between the 3. radial and 1. median usually more proximal *philocleon*. than in *phaeton*, the submarginal spots smaller; on the hindwing the discal band broken up into spots; the 3. and 4. spots reduced; the dentition of the harpe more regular and the dorsal process longer than in *phaeton*. The form of the ♀ similar to the ♂ is ♀-f. **dione** *R. & J.*; in the second form, the ♀-f. **coroebus** *Fldr.*, *dione*. the markings of the upperside are bluish and the discal band on the upperside of the hindwing is strongly widened posteriorly, also the discal spots of the hindwing beneath are reduced. East side of the Cordillera of Bogotá; Northern Venezuela. — **cleotas** *Gray* (= *lycortas* *Fldr.*). ♂: discal band of the upper surface *cleotas*. of the forewing more oblique than in the other subspecies; a row of nebulous bluish grey spots between the cell and the submarginal spots; harpe terminating in a two-pronged fork, whose prongs are straight and approximately of equal length. In the ♀ the middle vaginal lobe is short, the side one narrow and pointed. The two colour varieties are: ♀-f. **cleotas** *Gray*, similar to the ♂, and ♀-f. **adaea** *R. & J.*, in which both wings *adaea*. above have a discal and a postdiscal row of bluish patches. Brazil, from the province of Rio de Janeiro (Petropolis) to Rio Grande do Sul; according to Boisdual also in Uruguay, but the statement appears to us doubtful.

P. aristeus. Cell-spot of the forewing very large, the discal spot between the 3. radial and 2. median very long, forming with the cell-spot a large pale yellow area. The ♀ resembles the ♂, or the markings of the upperside are bluish and the discal band of the hindwing is broad; both forms on the underside with large, more or less distinct pale yellow cell-patch. South America and Panama. — **aristeus** *Cr.* (♂ = *aristeus*. *bari Oberth.*). ♂: the cell-spot of the forewing rhombiform, the discal spot placed before the 1. radial long, the next extending almost to the submarginal row, the third small and indistinct; discal band of the hindwing above only distinct posteriorly. Only one form of the ♀ known (CHAMBER's figure); forewing with long, indistinct grey-blue longitudinal streaks and hindwing with very broad bluish band. French and Dutch Guiana: one ♂ in coll. CHARLES OBERTHÜR. — **ctesiades** *R. & J.* Cell-patch of the forewing longish, nearly *ctesiades*. reaching to the base, two large, long discal spots, as well as a long triangular spot behind the 2. median and the cell; discal spots of the upper surface of the hindwing small, red. Upper Amazon. — **desmias** *R. & J.* *desmias*. Cell-spot shorter and narrower than in *ctesiades*, a small spot in the apex of the cell, a second distally to it, two large discal spots and behind the base of the 2. median a spot which is smaller than in *ctesiades*; hindwing as in *bitias*. Province of São Paulo, Brazil; one ♂ in coll. F. DUCANE GODMAN. — **bitias** *Godt.* *bitias*. (= *eurotas* *Fldr.*; *ctesias* *Fldr.*; *lacordairei* *Borre*) (13a). ♂: cell-spot of the forewing more transverse than in the preceding subspecies; discal band of the hindwing never complete, only indicated, or interrupted in the middle. ♀ dichromatic: ♀-f. **bitias** *Godt.* resembles the ♂; ♀-f. **therapes** *R. & J.* is similar to the ♀-f. *therapes*. *aristeus*, but the bluish streaks of the forewing are shorter and the band of the hindwing is narrower, also the cell-spot of the under surface of the forewing is partly pale yellow. Common on the east side of the Andes of Ecuador and Peru; upper course of the Rio Negro: Bogotá and Chiriqui; the last two localities appear to us doubtful. — **vilcanotus** *R. & J.* Cell-spot of the hindwing and costal spot of the hindwing *vilcanotus*. brownish yellow. Vilcanota, South Peru. **coelebs** *R. & J.* Cell-spot of the forewing narrow, transverse, *coelebs*. the discal spot between the 1. and 2. median narrow, triangular, not reaching to the cell, the submarginal spots large, indistinct grey-blue spots between them and the cell; hindwing with broad pale yellow discal band, submarginal spots large, pale yellow. On the underside the cell-spot of the forewing smaller than in *bitias* and *lenaus*. North-west Peru and Northern Central Peru (Tambillo, Chachapoyas), as well as South-west Ecuador. — **lenaus** *Doubl.* Cell-spot of the forewing transverse, not so oblique as in *bitias*, a discal *lenaus*. spot before the 3. radial, the discal spot behind the 1. median proximally narrowed and abbreviated; discal band of the hindwing complete, or narrowly interrupted. Rather common in South-East Peru and East Bolivia, the ♀ not known or at least not described.

P. judicæi *Oberth.* (13b). ♂: cell-spot of the forewing narrow, transverse and like the 4 discal *judicæi*. spots brown-yellow; hindwing strongly dentate, tailed. Cell-spot of the under surface of the forewing large, brown-yellow, the submarginal spots small; discal band of the hindwing dirty white, orange-red distally. — Only one ♂ in coll. OBERTHÜR, from Huambas, Amazonas, North Peru.

P. garamas. ♂: both wings on the upperside with a pale yellow discal band and a row of submarginal spots; margin of the hindwing strongly dentate, with spatulate tail; discal band of the underside of the hindwing brownish orange distally. The ♀ similar to the ♂, or the yellow discal band is absent and the hindwing has very strongly curved, more or less reddish, discal crescents. Central America. — **ab-** *abderus*. **derus** *Hopff.* (12b). ♂: forewing with 4 submarginal spots, often with indication of a fifth, the discal band of the hindwing enters the cell, the submarginal spots are absent; the orange-red teeth of the discal band of the hindwing beneath of equal breadth on both sides of the veins, shorter than in the following sub-

species. One form of the ♀ similar to the ♂, but the submarginal spots of the upper surface of the hindwing often indicated and the teeth of the discal band reddish-yellow also above: ♀-f. **abderus** Hopff.; in the second form, ♀-f. **amerias** R. & J. (12b), the forewing has besides the submarginal spots a row of brown-grey nebulous discal spots, the red crescents of the hindwing very large. Vera Cruz in East Mexico. — **garamas** Hbn. (♂ = *asclepius* Hbn.; *cinnatus* Boisd.; *concinatus* Gray). ♂: submarginal spots of the upper surface of the hindwing distinct; the yellow-red teeth of the discal band of the hindwing beneath less long than in *abderus*, the part of each tooth placed before the vein shorter than that placed behind it. Forewing beneath without nebulous brown-grey discal spots. The ♀-f. **amisa** R. & J. is similar to the ♂, being distinguished in colour from ♀-f. *abderus* chiefly by the distinct submarginal spots of the upperside of the hindwing; ♀-f. **garamas** Hbn. is similar to the ♀-f. *amerias*, but the nebulous discal spots of the upper surface of the forewing are crescent-shaped, the discal crescents of the hindwing are shorter, the blue spots larger and the submarginal spots thinner than in ♀-f. *amerias*. Both sexes larger than the East Mexican subspecies. West Mexico: Guadalajara, Cuernavaca, Oaxaca. — **baroni** R. & J. Forewing with 5 submarginal spots, the 5. spot much nearer to the margin than the 4.; submarginal spots of the hindwing indicated, the discal band entering the cell; on the under surface of the forewing the submarginal line interrupted at the 2. radial, the posterior part of the line being much nearer the margin than the broader anterior part. The dorsal prong of the fork of the harpe much shorter than the ventral prong. Guerrero, 1 ♂ in the Tring Museum. — **electryon** Bates. ♂: the cell-spot of the discal band of the forewing narrowed towards the costa; no submarginal spots on the upperside of the hindwing. Beneath the band of the forewing is strongly dentate on the disc and there are no nebulous spots present distally to this band; upper prong of the harpe curved downwards. The ♀ not known. Guatemala and (?) Honduras. — **syedra** Godm. & Salv. Cell-spot of the forewing of equal width anteriorly and posteriorly; 5–7 submarginal spots on the forewing, the 3. the largest; discal band of the hindwing more strongly dentate than in *electryon*, large blue spots distally to it; no submarginal spots. Beneath the apical area of the forewing and the basal area of the hindwing pale brown (as in *baroni*), the yellow-red margin of the discal band of the hindwing more deeply coloured than in *electryon* and broader between the veins. The ♀ similar to the ♂; the discal band of the upperside of the hindwing partly yellow-red distally. The upper prong of the harpe of the ♂ reduced to a tooth, the ventral prong long. Costa Rica and Chiriqui. A large form.

P. homerus F. (12a). Similar to the preceding species; the discal band of the forewing continued round the apex of the cell to the costal margin, the cell-spot sometimes isolated; discal band of the hindwing beneath non-dentate, brown, its proximal margin yellowish white, large black spots proximally to the red submarginal spots. — Larva on *Thespesea*, green above, brown beneath, marked similarly to that of *scamander*. Thoracic horn of the pupa short. The insect is apparently not rare at certain places in the interior of Jamaica, but is difficult to catch, as it flies at a considerable height above the ground. According to AARON occurs also in St. Domingo.

P. warscewiczii. Abdomen woolly beneath, brownish yellow like the breast. Forewing without cell-spot, 2 almost parallel rows of spots between cell and margin; hindwing with discal band and submarginal spots, tailed. Beneath the apical area of the forewing and the hindwing are pale brown (all that is visible when the butterfly holds the wings closed together); cell of the forewing with white or yellow spot; hindwing with dentate discal band. The ♀ not known to us. Ecuador to Bolivia; a mountain species. —

jelskii Oberth. Discal spots of the forewing and discal band of the hindwing not sharply defined. Discal spots of the underside of the forewing large and brown, the marginal area much widened before the middle; the brown postdiscal spot between the 3. radial and 1. median larger than in the other forms, the submarginal spot between the 1. and 2. median orange in the middle. The two prongs of the harpe (♂) straight, the upper one much longer than the lower. South Ecuador, North and North-West Peru. — **mercedes** R. & J. Discal spots of the forewing on the whole larger than in *jelskii*, the blue spots of the hindwing broader, the brown marginal area of the underside of the hindwing narrower before the middle, submarginal spot between the 1. and 2. median of the hindwing not orange beneath. The two prongs of the harpe (♂) straight, generally of equal length or the lower one somewhat shorter than the upper. East Peru: Huánuco and Junin. — **warscewiczii** Hopff. (= *sorataensis* Godm. & Salv.) (12b). Discal spots of the forewing much smaller than the submarginal spots; discal band of the hindwing broken up into spots, often only indicated, on the under surface often entering the cell and like the submarginal spots brown. The upper prong of the harpe (♂) strongly curved. South-East Peru and Bolivia.

P. cacicus. Forewing with interrupted discal band, a variable cell-spot, rarely absent, a row of bluish grey postdiscal spots and a row of yellowish white submarginal ones, the last or the last few of the submarginal spots more or less orange; on the hindwing a yellowish white median band, a postdiscal row of blue spots and a submarginal row of yellowish white ones. The ♀ occurs in 3 forms. Venezuela, Colombia, Ecuador and East Peru. — **cacicus** Luc. (12c). ♂: the cell-spot of the forewing, if present, more or less transverse. The 3 forms of the ♀ are: ♀-f. **cacicus** Luc., similar to the ♂; ♀-f. **zaddachi** Dewitz, discal band of the forewing not interrupted and like the large cell-spot brownish orange, hindwing without discal

band on the upper surface: ♀-f. **nais** *R. & J.* like ♀-f. *zaddachi*, but the markings of the forewing white, *nais*. Mérida in Venezuela, Colombia and Ecuador. — **inca** *R. & J.* The cell-spot of the forewing much more *inca*, oblique than in the preceding subspecies, forming with the median vein an acute angle; discal band of the hindwing convex distally, posteriorly strongly narrowed; the tail narrow, non-spatulate. Chanchamayo.

P. euterpinus *Godm. & Salv.* (12c). Tailless; markings of the upper surface yellowish red. The ♀ *euterpinus*, similar to the ♂, somewhat paler and larger. — From West Colombia to North Peru. The butterfly is an enlarged copy of the Pierid genus *Pereute*. The insect is usually considered as nearly allied to *zagreus*, but according to the structure and markings it belongs to the *homerus*-group near to *cacicus*. The butterfly is still very rare in collections.

C. Kite-Swallowtails.

Antenna with more distinct club than in the Aristolochia- and Fluted-Papilios, scaled on the upperside, but the scales, like those of the tibiae and tarsi, easily fall off, the fine sensory hairs are distributed as in the Fluted-Papilios. The dorsal spines of the tarsi are separated from the ventral spines by a spineless, impressed interspace. The wings in most species are thinly scaled, the scales often modified to fine hairs: the blue or green bands of many species of the Eastern Hemisphere are only covered with fine hairs on the underside, the pigment lying in the membrane of the wing, in the American Kite-Papilios also the membrane of the wing is green at least at the base, with the exception of the dark mimetic species. In a great number of these Papilios the 1. or 1. and 2. subcostals of the forewing are distally fused with the costa: the cell of the hindwing is mostly narrow and its anterior margin incurved between the subcostal and the 1. radial. The abdominal margin of the hindwing in the ♂ is widened and usually bent over; in this fold lies a scent-organ, which is rarely absent; the scent-scales are sometimes very different in nearly allied species; but the organ also varies geographically. The apical margin of the 8. abdominal dorsal segment of the ♂, which becomes visible after the removal of the genitalia, is smoothly scaled, the small scales standing erect; except in the Kite-Swallowtails this character is found in no American Papilio; the 10. dorsal segment of the ♂♂ of the American Kite-Papilios is likewise characteristic; this anal process is divided into three parts by two narrow incisions, only in *P. celadon* the process is simple in consequence of the absence of the two side parts. — Unfortunately the larva of only very few species is known. The 3. thoracic segment is swollen, as in the larvae of the Fluted-Papilios; the thoracic segments and the anal segment often bear dorsally short thorns, also traces of tubercles are usually found on the other segments; the pattern consists of small spots, transverse lines or short longitudinal streaks, eye-spots and oblique bands are wanting. — The pupa is shorter than in the other Papilios, the head and thorax are not at all or only weakly curved upwards, the thoracic horn is long and four-sided, the lateral carina forming the prolongation of the raised edge of the case of the hindwing; the abdomen has two dorsal carinae, which converge in front and behind: the anal segment is longer than broad. — The butterflies are in great part longwinged insects with triangular hindwing. The long-tailed forms with the wings spread out remind one of a paper kite. The Kite-Papilios are nimble fliers. Although the mimetic forms usually imitate the sluggish flight of their models (Aristolochia-Papilios, Pierids, Danaids etc.), yet they show great adroitness and speed when they take to flight in alarm. The ♂♂ often congregate in great crowds in moist places, at the edge of rivers, lakes, puddles etc., where they drink with a quivering motion of the half opened wings; they also visit flowers. The Kite-Papilios are insects of the open, sunny part of the wooded districts, of the clearings in the forests and their edges. Naturally this refers more to the ♂♂ than to the ♀♀; the latter, of many species at least, are only rarely taken by the collector, because they have different habits, remaining in the thickets and woods and not joining the crowds of ♂♂ drinking at the water; the ♀♀ of many very common forms are not yet known at all. The Kite-Papilios do not extend so far north as the Fluted-Papilios.

Lysithous-Group.

The species of the *lythisous*-group are characterised by red basal spots on the under surface of the wings. HAASE rightly recognised these forms, so similar in appearance to the Aristolochia-Papilios, as belonging to the Kite-Papilios; all other authors have erroneously classified them with the Aristolochia- and Fluted-Papilios. The bright-coloured larvae are striped longitudinally and bear a V-shaped saddle-spot before the middle; the thorax is spotted. The pupa is short; the abdomen enlarged in the middle. The species are found from Mexico to Argentina.

P. pausanis. A copy of *Heliconius clytia* L. According to BATES the butterfly certainly has the sailing and circling flight of the Heliconians, yet is not, like the Heliconians, a species of the forest shades, but is found on the muddy banks of rivers and lakes or flies round the tops of high trees. Wings above green-blue, with large pale yellow area on the forewing, hindwing short, often truncate. The scent-organ is wanting in the ♂. The ♀ resembles the ♂. From Costa Rica to Northern Brazil (Goyaz). — **prasinus** *prasinus*. *R. & J.* Wings above strongly metallic; discal spots of the forewing longer than in the following form, the white submarginal spots of the hindwing very small, the anterior ones only indicated, the red basal spots of the underside smaller than in the remaining subspecies. Costa Rica. — **cleombrotus** *Streck.* from *cleombrotus*.

West Colombia and probably Panama; as in *prasinus* the forewing without pale apical area; costal area of the upperside of the forewing almost black, in *prasinus* almost as metallic green as the disc; underside of the hindwing without pale (yellow-green or reddish) streaks between the veins. — **pausanias** *Hew.* (= *hermolaus* *Guen.*) (12a). Apex of the forewing with large grey area; under surface of the hindwing between the veins with pale streaks, extending to the submarginal spots. Central Colombia to Bolivia, Orinoco, the Amazons and Goyaz.

microdamas. **P. microdamas** *Burm.* (12a). A yellowish band from the costal margin of the forewing to the anal angle of the hindwing; under surface without red basal spots on the forewing, with 4 spots on the hindwing. ♀ similar to the ♂. — Paraguay, Northern Argentina, Caracá in Brazil; a lowland species.

protodamas. **P. protodamas** *Godt.* (= *hyperion* *Hbn.*). Forewing with yellowish area consisting of 3 large patches, or with 1 or 2 rows of spots; hindwing with yellowish grey-blue band; forewing beneath without basal spots, hindwing with 3. The scent-organ of the ♂ wanting. Larva black, with grey and white, partly yellow stripes, the thorax dotted with white and yellow. Thoracic horn of the pupa rather thin. Two individual forms of the butterfly are known: in f. **protodamas** *Godt.* the forewing has two rows of spots, the upper ones of which are more or less merged together; in f. **choridamas** *Boisd.* (13b) the forewing has a very large cell-spot and two discal patches, also large. — The butterfly is entirely Brazilian; it is found from Minas Geraes to Rio Grande do Sul: but the f. *choridamas* does not appear to extend so far south, being only known to us from the provinces of Rio de Janeiro and Minas Geraes.

phaon. **P. phaon** *Boisd.* Similar to the preceding species; the spots on thorax and abdomen red, the posterior abdominal segments with red lateral spots. Very variable. Spots on the upper surface of the forewing bluish yellow-grey or purer white-yellow; discal band of the hindwing grey-blue, rarely red. Under surface without distinct cell-streaks, forewing without basal spots, hindwing with 3. Scent-scales present in the ♂. Mexico to West Ecuador and Venezuela. The following forms have been described as species: ab. loc. **xenarchus** *Hew.*, hindwing with broad red band; ab. loc. **eridamas** *Reak.*, the red band of the hindwing narrow, the spots composing it separated: these two forms only known from East and South Mexico; ab. **phaon** *Boisd.* (13b), forewing with submarginal spots, but without discal spots, the band of the hindwing just entering the apex of the cell; ab. **ulopos** *Gray* (= *inmarginatus* *Oberth.*), forewing without spots or with only indications of them, band of the hindwing broad, entering more or less far into the cell; ab. **therodamas** *Fldr.*, with discal and submarginal spots on the forewing and narrow, slanting band on the hindwing, separated from the cell; ab. **metaphaon** *Butl.* has on the hindwing a very large blue-green discal area, occupying a good part of the cell; in ab. **pharax** *Godm. & Salv.* the hindwing has a red anal spot and the discal band is remote from the cell. All these forms are connected with one another by transitions.

euryleon. **P. euryleon.** The spots of the breast and abdomen red, the posterior abdominal segments with red lateral spots. Forewing above with yellowish grey area before the hindmargin, hindwing with red discal area or band. Beneath the forewing without red basal spot, the hindwing with three, but the spot placed in the cell commonly only indicated or quite absent, the discal band smaller than above, pale red. ♀ similar to the ♂ or different from it; in the latter case forewing with cell-spot and two discal bands, all white, recalling *pausanias* and *protodamas* f. *choridamas*. Scent-organ of the ♂ usually present. Costa Rica to Ecuador. — **clusoculis** *Bull.* (13c). Discal area of the forewing white-grey; the red band of the hindwing broad, always entering the cell. ♀ similar to the ♂, the red band of the hindwing somewhat broader. Costa Rica; Chiriqui. — **pithonius** *R. & J.* ♂: forewing with small or large grey spot; hindwing with 3–5 red discal spots, the red submarginal spots of the under surface of the hindwing very small or only indicated. ♀ with large cell-spot on the forewing and 2 large discal spots. West Colombia and Cauca Valley. — **euryleon** *Hew.* (13c). ♂: hindwing above mostly with 4 spots placed close to the cell and two small, less distinct spots before the abdominal margin; the discal spots on the underside pale red. ♀: the cell-spot of the forewing narrowed anteriorly, the band of the hindwing entering the cell. Magdalena Valley, Cordillera of Bogotá. — **haenschi** *R. & J.* ♂: area of the forewing lighter grey than in *euryleon*, composed of two spots, the anterior spot projecting distally; hindwing with small cell-spot, which is rarely absent, and 3–5 spots placed close to the cell; beneath the forewing has a large white spot between the 1. and 2. median, a grey spot behind it; hindwing with 3 pale red spots, the 1. and 2. touching the cell, a 4. spot often indicated. ♀: the cell-patch of the forewing does not extend across the cell, band of the hindwing running from the 1. radial to the abdominal margin, entering the cell, behind the cell proximally whitish, as in the ♀ of the *Aristolochia*-Papilio *P. iphidamas calogyne*. ♂ with scent-organ. In Western Ecuador. — **anatmus** *R. & J.* ♂: the grey area of the forewing extending from the hindmargin costad as far as the 2. median or beyond, often a grey streak in the cell; hindwing with 3 red spots, separated from the cell, often only the 3. spot distinct; beneath the forewing without white spot and the discal spots of the hindwing usually grey. ♀ not known. Scent-organ absent in the ♂. East Ecuador.

hipparchus. **P. hipparchus** *Stgr.* (13d). ♂: forewing with a row of grey submarginal spots; hindwing with pale reddish discal band, extending from the 1. radial to the abdominal margin. ♀ not known. Cauca Valley, Colombia.

P. harmodius. ♂ and ♀ different. The spots on head, thorax and coxae yellowish white. ♂: forewing somewhat transparent apically, before the hindmargin a white area of variable extent, but never reaching to the 3. radial; hindwing with a band of red discal spots. Beneath the cell of both wings streaked with black, forewing with red costal basal spot, hindwing with 3 basal spots. In the ♀ the hindwing similar to the ♂, or the macular band white or yellow; the forewing either without spots, or with white cell-patch and two large discal patches. Colombia to Bolivia; a species of the Andes, very common in the eastern valleys of Ecuador, Peru and Bolivia. Larva not known. — **isus** Oberth. (= aristogiton Stgr.). ♂: the white area of the forewing large, extending from the hindmargin to the 2. median or beyond; discal band composed of 6 or 7 white-centred spots. ♀ not known. — Cauca Valley, Colombia. — **halex** R. & J. Forewing as *halex*. in the preceding subspecies; hindwing with 5 red discal spots. ♀ on the forewing with white area from the 3. radial to the 2. median and a small cell-spot; hindwing with 5 pale red discal spots. Colombia; in Bogotá-collections. — **xeniades** Hew. ♂: the white spot of the forewing very variable, always extending to the hindmargin of the wing, usually excised at the costal side, always small on the underside; hindwing with 3—5 discal spots, which are red above, rarely whitish in the middle, and beneath always reddish white with red distal margin. ♀: dichromatic: ♀-f. **androna** R. & J. (13d) with quite small grey scaling in and behind the cell of the forewing and 5 red discal spots on the hindwing; the second form, ♀-f. **virginia** Kirby, is very similar to the ♀ of *P. erlaces lucydes*, forewing with large white cell-spot and two large discal patches, band of the hindwing white with faint red margins. *Xeniades* occurs in Ecuador and West Colombia. — **imaus** R. & J. (14a). Not constantly different from the ♂ of the following subspecies, forewing above mostly with white streak at the hindmargin, beneath the white spot is usually smaller than in *harmodius* Doubl. ♀ as the ♀-f. *virginia*, but the cell-spot narrowed anteriorly, the anterior discal spot reduced and the band of the hindwing yellow above, almost white beneath. Eastern slopes of the Andes of North and Central Peru. — **harmodius** Doubl. (13c). ♂: forewing above and beneath always with large white spot, not quite reaching to the hindmargin. ♀: the white cell-spot does not extend across the cell; three discal spots, the 1. small, the 2. as long as the 3.; hindwing with red discal spots, larger than in the ♂. South-east Peru (from Chanchamayo southwards) and Bolivia. The ♂♂ common, of the ♀ only 1 specimen known (in coll. CHARLES OBERTHÜR).

P. trapeza R. & J. (13c). Forewing narrower in the middle than in *harmodius*, the hindmargin shorter, a white spot at the hindmargin, not extending to the 2. median; hindwing triangular, sharply dentate, with 2 to 4 red spots from the hindmargin forwards, the posterior spot the largest. Beneath the white hindmarginal spot of the forewing is longer than in all the forms of *harmodius*. ♀ unknown. — East Ecuador and North-East Peru.

P. xynias Hew. (13c). Forewing with large pale green area at the hindmargin; hindwing acutely dentate, with short, narrow tail and a few red discal spots posteriorly. Beneath the forewing has a white, very faintly green hindmarginal spot, which is smaller than the spot on the upper surface. No scent-scales. ♀ not known. — Eastern slopes of the Andes of Bolivia and Peru.

P. ariarathes. Another widely distributed and very variable species, which has more spiny tibiae and a narrower cell in the hindwing than the allied species. Spots on head and breast yellowish grey. Forewing beneath with 2 red basal spots, the hindwing with 3. In the ♂ the forewing usually with grey-white or yellowish band or area from the hindmargin forwards; hindwing with red discal spots, of which often only the one placed at the abdominal margin is distinct. ♀ almost always with white discal spots on the forewing. Scent-scales of the ♂ present. Larva unknown. Colombia to Bolivia, distributed eastwards to Pará and Goyaz. The butterfly is individually and geographically variable; the ♀♀ resemble the ♀♀ of *Aristolochia-Papilio* and adopt in the different districts their likewise variable dress. The forms all intergrade. We differentiate 6 geographical forms, whether correctly must be ascertained by further investigations based on a larger material than we have seen. The butterfly according to Bates flies with great rapidity in sunny places near plantations; it is no rarity, but is not taken in great numbers. — **ariarathes** Esp. (= *acestes* Bois.) (14a). ♂: forewing with large white spot from the hindmargin to the 2. median, almost as large beneath as above; on the hindwing 4 to 6 separated discal spots, placed separate from one another and from the cell. ♀ with 5 or 6 red discal spots on the hindwing, three long, extending nearly or quite to the cell; in ♀-f. **ariarathes** Esp. the forewing has 1 to 3 white discal spots and often a narrow cell-spot; in ♀-f. **eumelea** R. & J. these white spots are only indicated. French and Dutch Guiana. — **menes** R. & J. ♂: forewing with white band, extending from the hindmargin to the 1. or 2. median, the posterior spot often small or absent, the spot before the 2. median 4—6 mm. long, also always present beneath; hindwing with 3 or 4 red spots midway between cell and margin. ♀ with large discal spot from the 3. radial to the 1. median and a smaller one behind it, sometimes also with indication of spots before the 3. radial and in the cell; 5 or 6 discal spots on the hindwing, remote from the cell. British Guiana. — **evagoras** Gray (13d). ♂: forewing with narrow band, placed at the 3. radial about midway between cell and outer margin or nearer to the cell; beneath the band is replaced by 2 or 3 distinct spots; discal spot of the hindwing partly near to the cell, the band more curved than in the other forms. ♀ with 3 white or yellowish

discal spots and a rather large cell-spot on the forewing; the apical half or two-thirds of the cell of the hindwing red, as are also 6 large discal spots, abdominal margin at least partly red. Venezuela. -

metagenes. **metagenes** *R. & J.* ♂: forewing usually with a band reaching from the hindmargin to beyond the 3 radial, merely indicated on the underside; hindwing with 4 or 5 spots placed separate from the cell. ♀: forewing with the long white discal band which is also peculiar to the *Aristolochia*-Papilios *P. anchises theios* and *P. aglaope*, this band consists of two large spots with a smaller one placed before and behind them; hindwing with 6 red spots, 3 of which are contiguous to the cell. Pará. — **gayi** *Lucas*. ♂ and ♀ very variable: 3 principal forms: f. **anargus** *R. & J.* (13d), forewing without band or spots; f. **cyamon** *Gray* (= *charoba Kirby*) (13d), ♂ with narrow band on the forewing, on the whole somewhat more distally placed than in the ♂ of *eragoras*, ♀ with narrow, indistinct band on the forewing, with cell-spot on the hindwing, the spots on the hindwing sometimes yellowish white; in f. **gayi** *Luc.* (= *aristagoras Fldr.*; *arianus Staud.*) the ♂ has on the forewing a more or less square hindmarginal spot, whilst the ♀ has 1 or 2 large discal spots, usually also a small third spot and often a cell-spot in addition. These different forms are not separated geographically. Distributed from Colombia to Bolivia and the Amazon downwards to Manáos. — **leuctra** *R. & J.* ♂: forewing with a pure white area, of almost even width, reaching from the hindmargin to the 1. median, above about 6 mm. broad and on the underside only a trifle narrower; hindwing with 6 long red discal spots, the 3 middle ones contiguous to the cell. Goyaz, Brazil.

ilus. **P. ilus** *F.* (= *hostilius Fldr.*; *guaco Stgr.* (14a). ♂♀: under surface without red basal spots on the forewing, with 4 red basal spots on the hindwing. Forewing with or without a patch in the extremity of the cell, with 2 or 3 white spots on the disc, the posterior one, placed behind the 3. median, the largest. North Venezuela, Northern Colombia, Panama; rare in collections.

P. branchus *Doubl.* Head and breast with red dots, a spot on the forecoxa white. Wings opaque; forewing with or without white spots; hindwing with broad red discal band. Under surface without red basal spots on the forewing, with 4 such spots on the hindwing. Sexes similar. In the f. **branchus** *Doubl.* (14b) the forewing has a variable white central area, which is absent from f. **belephantes** *Godm. & Salv.* — Mexico to Costa Rica.

belesis. **P. belesis** *Bates* (14b). Similar to the preceding species, hindwing with a band of 6 to 7 red spots, parallel to the margin, placed nearer to the margin than to the cell. Forewing in f. **belesis** *Bates* without white spot, in f. **hephaestion** *Fldr.* with a spot between the 2. and 3. radial and sometimes the indication of a second spot behind the 3. radial. — Mexico to Nicaragua.

P. thymbraeus. The small spots on head and breast grey-yellow, often slightly reddish. Upperside of the wings slightly but yet distinctly metallic blue or green; forewing without markings, but with white fringes; hindwing with a slender tail and 1 or 2 rows of spots between cell and margin. Under surface with red costal basal spot on the forewing and 4 basal spots on the hindwing. Larva on Chirimoya: the thorax dotted with blue and yellow; striped with white and black from the 4. segment backwards, the white stripes with small blue and yellow spots, the sides blue, from the 5. segment dotted with yellow. Pupa green, as in the allied species, appearing constricted at the base of the abdomen. The butterfly flies in the open country the whole year through, and is rather common at a height of 500 to 1560 m. — *thymbraeus*. **thymbraeus** *Boisd.* (14b) is distributed from East Mexico to Honduras. The hindwing in ♂ and ♀ has 2 rows of red spots. — In **aconophos** *Gray* the hindwing has only one row of red spots, the discal row is absent. Central and West Mexico.

P. lysithous. A polychromatic species. The different individual forms with one exception were originally described as species and have been regarded as such until recently. The forms are connected with one another by intergradations; moreover, the specific identity of 3 of the varieties (*pomponius*, *rurik*, *lysithous*) has been proved by breeding. Underside of the forewing with 2 red basal spots, hindwing with 3; all the forms with a tail. Larva on Anona, resting by day on the upperside of a leaf at the middle vein, on the lower branches and root-shoots, near Petropolis all the year round, except in June and July (middle of the dry season); black with yellow longitudinal stripes and white-yellow saddle-spot. The pupa as in the allied species green with yellow lateral streak. Brazil and Eastern Paraguay. The principal forms, which do not everywhere occur together, are the following: f. **platydesma** *R. & J.* (= *harrisianus auct.*) (14b), the white band of the forewing very broad, continued over the cell to the costal margin; *harrisianus*. f. **harrisianus** *Swains.* (= *claudius Boisd.*; *athous Fldr.*), the white band of the forewing broad posteriorly, strongly narrowed anteriorly, not entering the cell, the part from the lower angle of the cell to the costal margin narrow or absent, as in the preceding form the posterior submarginal spots of the hindwing large; *oedipus*. f. **oedipus** *Fldr.* (= *sebastianus Oberth.*) (14a), forewing with double spot from the 1. median backwards, hindwing without white band, the 4 posterior submarginal spots large; f. **lysithous** *Hbn.* (14a), band of the forewing narrow, often abbreviated (ab. **brevifasciatus** *Weym.*), hindwing with small submarginal spots, the discal band usually only extending to the 1. median, sometimes longer and more distal (ab. **extendatus** *Weym.*); f. **rurik** *Eschsch.* (= *rurikia id.* in tab., *laus Boisd.*), band of the forewing abbreviated, hindwing without white band, the 4 posterior submarginal spots rather large; f. **pomponius** *Hopff.*, band of the fore-

wing indicated, or like that of the hindwing entirely absent: f. **eupatorion** *Luc.*, both wings without discal *eupatorion*. band, forewing with yellowish marginal band and the marginal spots of the hindwing enlarged (probably an aberration, only the type known, in col. CHARLES OBERTHÜR).

P. asius *F.* (= *astyages Drury*; *manlius Porty*) (14d). A rather common Brazilian butterfly, distributed from Bahia to Rio Grande do Sul and westward into Eastern Paraguay. A broad band, narrowed towards the costa on the forewing, beginning at the costal margin of the forewing distally to the cell and ending before the abdominal margin of the hindwing: hindwing triangular, with long tail. On the underside the hindwing has 4 red basal spots, two of these placed at the costal margin, in addition a red streak before the abdominal margin and 3 red spots near the anal angle. The ♀ similar to the ♂, very rare in collections. The larva not known to us.

Marcellus-Group.

In the *marcellus*-group there is on the underside of the hindwing a red line running from the costal margin to the anal angle, which at least at the costal margin is edged with black at both sides. The species have bands on the wings, and the triangular hindwing is tailed. The 1. subcostal of the forewing is free: in one species (*bellerophon*) it is entirely absent.

P. marcellus *Cr.* (= *ajax auct.*) (14c). The common Asimina Swallowtail of North America. Antenna brown-yellow; tibiae and tarsi green: forewing with 8 greenish white bands, the green colour in the membrane; the red line of the hindwing beneath margined with white proximally. Scent-scales of the ♂ long. The larva with 6 fine black transverse lines on each segment, the lines usually partly contiguous. The frontal prominences of the pupa divergent, the thoracic horn vertical, the lateral carina continued to the cremaster, not interrupted. Foodplants: Asimina, especially *A. triloba*, also Ericaceae and Lauraceae. This species is one of the classical examples of seasonally variable butterflies. In the specimens which hibernate as pupa once or twice the hairs of the frons are long, whilst they are short in the butterflies emerging from non-hibernated pupae. The principal forms are: forma hib. **marcellus** *Cr.* (= *walshi Educ.*), the spring *marcellus*. form with broad white bands, sometimes red discal spots appearing on the upper surface of the hindwing (ab. **abboti Educ.**); forma hib. loc. **floridensis** *Holl.* is the spring form from Florida, which has broader *abboti*. black bands than *marcellus*; forma hib. **telamonides** *Fldr.* (14c) is the later spring form, which forms the *floridensis*. *telamonides*. transition to the summer form, forewing somewhat longer than in f. hib. *marcellus*, the black bands broader, the fringes of the tail more extended white; forma aest. **lecontei** *R. & J.* (= *marcellus auct. non Cramer*), *lecontei*. large, the black bands broad. — *P. marcellus* occurs from Southern Canada to Florida and Texas and westward into the prairie districts of the Mississippi Plain. Very common where pawpaw trees are found. The flight of the summer brood is more elegant than that of the spring specimens. The butterfly often travels northwards in considerable numbers, flying swiftly near the ground. Indeed in the northern districts where it occurs it is only an immigrant, not a permanent inhabitant.

P. marcellinus *Doubl.* (= *sinon F. non Poda*) (14c). Forewing with pale green bands and a row *marcellinus*. of submarginal spots; hindwing with black submedian band extending to the black distal margin; the red line on the under surface of the hindwing broad, reaching to the brown margin. Scent-scales of the ♂ long. — Jamaica.

P. celadon *Lucas* (= *sinon Godt. non Poda*) (14c). Similar to the preceding species, but on the *celadon*. forewing the pale green discal band is continuous with the 3. and 4. pale green cell-bands, not with the 4. and 5.; the red line on the underside of the hindwing thin, shorter than in *marcellinus*. The anal tergite of the ♂ is not divided, as the lateral prongs are absent. — Cuba; perhaps also in Florida.

P. zonaria *Btlr.* (= *sinon F. non Poda*) (14c). The pale bands narrow; the 4. and 5. pale green *zonaria*. cell-bands of the forewing continuous with the discal band, narrow, separated from one another. — Haiti.

P. philolaus *Boisd.* (14d). Antenna black; the 7. pale green band of the forewing only represented *philolaus*. by a spot; hindwing with 2 red spots posteriorly; on the under surface the red line of the hindwing edged with black at both sides, undulate anteriorly. Scent-scales of the ♂ short, broad, irregular, produced in a number of filaments. The ♀ in 2 forms: ♀-f. **philolaus** *Boisd.* similar to the ♂, the underside paler; ♀-f. **niger** *Eimer* (= *nigrescens Eimer*; *felcis Fruhst.*) (14d), the pale green bands of the membrane of the wings *niger*. scaled with black, the wings therefore black with slight traces of the bands. — Larva not known. The butterfly common from Mexico to Nicaragua, in low situations, often resting in crowds on the sand at the edge of rivers.

P. xanticles *Bates* (= *plaesiolus Stgr.*) (16b). The pale bands yellow, the 7. band of the forewing *xanticles*. continuous with the broad discal band, not as in *philolaus* replaced by a single spot. Two forms of the ♀; the one similar to the ♂, which doubtless exists, has not yet to our knowledge been discovered: the second form, ♀-f. **philenora** *Haase* (= *sheba R. & J.*), is black, with the exception of the yellow submarginal and *philenora*. the red anal spots. Scent-scales of the ♂ as in *philolaus*. — Panama and at the foot of the Santa Marta in North Colombia.

P. oberthueri *R. & J.* (14d). Similar to *philolaus*, the pale bands broader, the white discal area at *oberthueri*. the 2. median about 1½ times as broad as the black marginal area; hindwing narrower than in *philolaus*,

the black median band only extending to the cell; the latter less pointed than in *philolaus*. The scent-scales of the ♂ longer. The ♀ not known. — San Pedro Sula, Honduras (in coll. CHARLES OBERTHÜR). Our figure is too small.

arcesilaus. **P. arcesilaus** Lucas (= *anaxilaus* Fldr.) (14d). Antenna black. Forewing with 6 greenish bands and a row of submarginal spots, the 6. band short, separated from the discal area. Scent-scales of the ♂ long. — North Venezuela and Colombia.

epidaus. **P. epidaus**. Antenna black: wings white, semitransparent, distally almost glassy. The 2. black band of the forewing extends to the hindmargin beyond the middle and the discocellular band is continued to the 2. median or to the posterior angle of the wing. Larva not known. Mexico to Honduras. — **epidaus** Doubl. (15c). The 2. black band of the forewing not more than half as broad as the light interspace between the 2. and 3. bands, generally narrower, the 5. band not extending far beyond the 2. median, not reaching to the marginal band; the posterior part of the median band, on the underside, thin or merely indicated. From East Mexico to Nicaragua, from whence specimens of this form have recently come. —

tepicus. **tepicus** R. & J. 1. and 2. bands of the forewing broader than in the preceding form, 5. band posteriorly joined to the marginal band: hindwing longer and the costal margin shorter than in the other forms. West Mexico: province of Jalisco. — **fenochionis** Godm. & Salr. 5. band of the forewing prolonged to the hinder angle, hindwing much more extended black than in the previous subspecies. South-Western Mexico: Oaxaca, Guerrero.

bellerophon. **P. bellerophon** Dalm. (= *coresilaus* Godt., *swainsonius* Swains.) (15a). The only *Papilio* in which the 1. subcostal of the forewing is absent. Forewing semitransparent, with 4 black bands. ♀ similar to the ♂, with somewhat broader hindwing. Scent-organ of the ♂ woolly. — Brazil: Minas Geraës, Parana, Santa Catarina, rather rare.

Protesilaus-Group.

The species of the following *protesilaus*-group with the exception of *agesilaus* are hard to differentiate without the assistance of their genitalia. The red line on the under surface of the hindwing is only edged with black at one side. These white, black-banded butterflies include some of the commonest *Papilios* of South America; but this applies only to the ♂♂, the ♀♀ on the contrary being very rare in collections. The ♂♂ often rest in dense clusters on damp sand or mud. The larva of only one of the species (*P. stenodesmus*) is known with certainty: it is green, dorsally spotted with black and with transverse bands, sometimes the black markings are absent until a transverse line on the prothorax. The dorsal horn of the pupa is very long. The butterflies are tropical.

fortis. **P. agesilaus**. Easy to recognise by the red line of the hindwing being edged with black distally. Distributed from Mexico to Bolivia and Goyaz in Brazil, not yet known from Nicaragua and Costa Rica, where, however, the insect certainly occurs. — **fortis** R. & J. from South-West Mexico: Guerrero, Atoyac, Oaxaca. The black bands broad, 1. and 2. bands of the forewing about $\frac{2}{3}$ as broad as the interspace, both continued to the hindmargin, or the 2. band at least extending beyond the 2. submedian; the white submarginal band not broader than the black postdiscal band, the latter not divided longitudinally by a pale line; abdominal margin of the hindwing black, the two red anal spots surrounded with black. —

neosilaus. **neosilaus** Hopff. The black bands narrower than in *fortis*, the 1. and 2. bands of the forewing at most half as broad as the white interspace, the transparent submarginal band broader than the black postdiscal band; abdominal margin of the hindwing partly white, the red anal spots anteriorly broadly edged with white, much less broadly surrounded with black than in *fortis*. East Mexico, Guatemala, British Honduras, Honduras.

eimeri. **eimeri** R. & J. The transparent submarginal band of the forewing between the 4. and 5. subcostal at most as broad as the black postdiscal band which is placed at its proximal side. West Colombia.

agesilaus. upper Cauca Valley and Panama. — **agesilaus** Guér. (= *conon* Hew., *septemlineatus* Eimer) (15c). Postdiscal band of the upperside of the forewing without light median line, narrower than the costal half of the transparent submarginal band; subbasal band of the upper surface of the hindwing only represented by a thin streak placed on the 2. median. Very variable in size. Central and East Colombia, North *autosilaus*. Venezuela. — **autosilaus** Bates. Postdiscal band of the forewing divided longitudinally by a pale streak, subbasal band of the hindwing present on the upperside. Orinoco, Guiana, the Amazon, Goyaz, the eastern slopes of the Andes from Ecuador to Bolivia, as well as Paraguay, not yet known from South-East Brazil: like the preceding subspecies very common.

P. glaucolaus. In order to differentiate this and the following species with certainty, it is necessary to compare specimens from the same districts, and at times to take the sexual organs into consideration. In *glaucolaus* the black postdiscal band of the forewing is widely separated from the lower angle of the cell, or the teeth of the hindwing are very obtuse and the posterior submarginal spots suffused with brown. Scent-scales of the ♂ as long as in *protesilaus*; the harpe has at the dorsal edge a very long tooth and the central and ventral processes are short, the latter not reaching to the ventral edge of the clasper. From Panama to Guiana, Upper Amazon, southwards to Matto Grosso, not yet known to us from South-East Peru, Bolivia, Paraguay, Brazil proper and the Lower Amazon. Only ♂♂ in collections. A common species. *glaucolaus*. Larva not known. — **glaucolaus** Bates (15a). Greenish, bands 1 and 2 of the forewing not extended beyond

the 2. submedian vein, the 6. band 2 to 3 mm distant from the lower angle of the cell, not narrowed before the 2. radial, the transparent submarginal band at least twice as broad at the 5. subcostal as the black marginal band. Panama; Colombia, with the exception of the province of Cauca, perhaps also in North Venezuela. — **melaenus** *R. & J.* The black bands broader than in the preceding form, the transparent submarginal interspace of the forewing usually only little or not at all broader at the 5. subcostal than the marginal band, in some specimens, however, much broader, in which case the interspace between bands 5 and 6 is narrowed correspondingly. West Colombia and upper Cauca Valley. — **leucas** *R. & J.* Wings only distinctly green towards the base; postdiscal band of the forewing narrowed near the lower angle of the cell and usually before the 2. radial. Hindwing more obtusely dentate than in *protesilaus*, the submarginal spots tinged with brown, 2. band of the forewing from the cell backwards narrower above than beneath, the side of the frons white. The harpe of *leucas* more obtuse than in *glaucolaus*, the dorsal tooth narrower and the central process longer. Orinoco, Guiana, the Amazons, East Ecuador, East Peru and Matto Grosso; common.

P. molops. The 1. and 2. black band of the forewing broad and both or at least one of them extending to the hindmargin, the 4. band usually reaching quite across the cell. The denticulate, deflexed dorsal margin of the harpe rounded-dilated. ♀ unknown. Tropical South America, widely distributed, but only singly among the white butterflies of this group. — **molops** *R. & J.* Antenna brownish yellow; the black lateral stripe of the abdomen as broad as the yellow-white stripe placed at its dorsal side; 1. and 2. band of the forewing broad, the 1. not extending to the hindmargin, the other bands likewise broad, the 6. especially is broader than in all the other forms of the *protesilaus*-group, being at least as broad as the interspace between bands 5 and 6; this 6. band close to the lower angle of the cell. Dorsal margin of the harpe abruptly dilated. North-West Ecuador and West Colombia. — **hetaerius** *R. & J.* (15b). Easy to differentiate from the preceding form by the thinner black bands: it is so similar to the *protesilaus* forms occurring together with *hetaerius* as to be easily mistaken for them, but is much smaller than the Colombian *protesilaus* and has a much less sharply dentate hindwing. Sides of the frons always white; 1. and 2. band of the forewing extending to the hindmargin, or the 2. band very little abbreviated; the white submarginal lunule between the 1. and 2. radial of the hindwing narrower than the corresponding marginal lunule; the interspace between the subbasal and median band on the under surface of the hindwing longer than in *protesilaus*. Harpe somewhat different from the harpe of *molops*, dorsal and ventral edges more denticulate, the ventral process longer and curved towards the ventral edge of the clasper. Guiana, Amazons, Colombia, Ecuador (except the western side), Peru and Bolivia. — **megalurus** *R. & J.* Antenna black as in the Brazilian *protesilaus*; frons laterally white; the white subdorsal line of the abdomen thin; 1. and 2. band of the forewing extend to the hindmargin, 6. band separated from the angle of the cell; the black markings of the hindwing somewhat more developed than in *hetaerius*, the red anal spot longer; tail long and broad. Dorsal edge of the harpe less dilated than in the other forms of *molops*. Brazil: Leopoldina, but probably more widely distributed.

P. protesilaus. Submarginal spots of the hindwing white, rarely slightly yellowish, hindwing more strongly dentate than in *glaucolaus*, the 1. and 2. band of the forewing on the whole shorter than in *molops*. Frons sometimes entirely brown-black. The scent-scales very long and thin. The dorsal edge of the harpe deflexed, lying flat on the harpe, strongly dentate. Larva not known. Mexico to South Brazil. — **penthesilaus** *Fldr.* Large; dorsal streak of the abdomen very narrow; 1. band of the forewing extending to the 2. submedian vein, 2. band a little beyond it; 4. band short, triangular, rarely reaching to the 2. cell-fold; 6. band separate from the angle of the cell, somewhat narrowed before the 2. radial, posteriorly almost always separated from the marginal band; red anal spot of the hindwing large, marginal teeth partly strongly projecting, fringes white except at the extremities of the veins. Apex of the harpe pointed, dorsal edge rounded. Mexico, the only form of this group which occurs so far north; it is found in Vera Cruz, Yucatan, Atoyac, Oaxaca etc., in wooded districts, and in the South intergrades completely with the next form. — **macrotilaus** *Gray* from Guatemala, British Honduras, Honduras and Nicaragua. 1. and 2. bands of the forewing narrow, the 4. is absent or is only represented by a costal spot, the 6. somewhat angled at the 2. radial and narrowed costad, posteriorly connected with the marginal band; the latter less sharply defined and somewhat paler than in *penthesilaus*, transparent, submarginal band with hairy scales; red anal spot of the hindwing narrower than in *penthesilaus*. Apex of the harpe truncate, central process shorter than in the Mexican form, spatulate, strongly dentate at the apex, ventral process not extending to the clasper, curved backwards. — **leucones** *R. & J.* Black dorsal line of the abdomen absent or thin; 1. band of the forewing thin, 2. extending to the hindmargin or nearly to it, the interspaces between 1. and 3. of equal breadth at the median vein; the white marginal and submarginal spots of the hindwing large, the margin only black at the extreme tips of the veins, but the fringes from the costa to the 2. radial partly black; red anal spot large. Harpe similar to that of *macrotilaus*, some of the teeth of the ventral edge enlarged, ventral process non-dentate, not extending to the lower edge of the clasper, the teeth of the spatulate central process more or less curved dorsal. Manauré, at the foot of the Santa Marta in North Colombia; probably this form inhabits the north coast of Colombia. — **dariensis** *R. & J.* Dorsal line of the abdomen

broad, the margin of the hindwing between costa and 1. radial entirely or almost entirely black. The dilated part of the dorsal edge of the harpe distally with triangular tooth, ventral process denticulate from the base to the tip. Very similar to *archesilaus*, forewing at the base broader green, the black bands somewhat thinner, band 1 not extending beyond the 2. submedian, band 4 rarely reaching to the 2. cell-fold; hindwing less strongly dentate than in *archesilaus*, the subbasal band of the forewing beneath narrower. Wings of the ♀ slightly yellowish, especially the anal region of the hindwing. Costa Rica, Panama and the islands off the West coast of Panama. — ***archesilaus* Fldr.** (= *rubrocinctus* *Eimer* partim) (15a). On the whole considerably larger than *protesilaus*, hindwing more strongly dentate, the apex of the cell of the hindwing beneath more or less edged with red. Colombia, West Ecuador and North Venezuela. — ***protesilaus* L.** (15c). Bands 1 and 2 of the hindwing usually extend beyond the 2. submedian, band 4 mostly goes beyond the middle of the cell and sometimes reaches to its hinder margin, the transparent submarginal band has at least in the costal third brownish scales; hindwing more strongly dentate than in *glaucolaus leucas*. Frons in specimens from the Andes often entirely brownish black. Dorsal edge of the harpe dilated into a tooth, which is sometimes absent in specimens from the Andes. Orinoco, Guiana, the Amazon from Pará upwards, and Eastern slopes of the Andes of Ecuador, Peru and Bolivia. — ***nigricornis* Stgr.** (= *leilus* *Swains.* partim). Antenna usually black; frons brownish black, not white at the sides. Dorsal edge of the harpe with large tooth. East Paraguay and Brazil.

***helios*.** ***P. helios* R. & J.** (15b). Antenna and frons brownish black as in *nigricornis*. Wings brownish; forewing transparent; hindwing more sharply dentate than in *nigricornis*, the black postdiscal band straight, not interrupted posteriorly as in the *protesilaus* forms, the marginal and submarginal bands yellowish. Under surface more yellow than upper; the red line of the hindwing distally edged with white. Dorsal edge of the harpe not dilated into a large tooth, the apex of the harpe pointed, ventral process not denticulate. — Brazil, only known to us from Parana.

***orthosilaus*.** ***P. orthosilaus* Weym.** (16c). Antenna yellow-brown, not black. Frons yellowish white at the sides. Forewing transparent; hindwing strongly dentate, above also with a median band, the postdiscal band and the black margin merged together into a broad marginal band, the yellowish marginal and submarginal lunules smaller. — Paraguay and Goyaz in Brazil; rare, to our knowledge only 3 ♂♂ at present known.

***earis*.** ***P. earis* R. & J.** (16a). Antenna dark yellowish brown. Frons yellowish at the sides. Wings slightly yellowish, beneath slightly reddish; bands narrow, 4. band of the forewing reduced to a small spot, 6. band close to the lower angle of the cell; the yellowish marginal and submarginal spots of the hindwing narrow, above and beneath smaller than in the name-typical *protesilaus*; hindwing beneath with long arrow-shaped patch before the abdominal margin, this patch reduced in *protesilaus*. Dorsal margin of the harpe slightly widened, ventral process non-dentate, not extending to the lower edge of the clasper, central process short, broad, spatulate, strongly dentate. ♀ not known. — Eastern Ecuador, probably more widely distributed.

***stenodesmus*.** ***P. stenodesmus* R. & J.** (15b). Antenna black. Frons laterally white. Forewing distally transparent, the bands thin, interspace between band 1 and 2 half as wide again as that between bands 2 and 3; hindwing longer than in *protesilaus* and *telesilaus*, usually slightly yellowish, strongly dentate, median band of the under surface somewhat curved, placed nearer to the extremity of the cell than in *protesilaus* and *telesilaus*. Dorsal edge of the harpe not dilated. For larva and pupa see p. 40. — Paraguay; Brazil, from Petropolis to Blumenau; a common species, usually mistaken for *protesilaus* and *telesilaus*.

***telesilaus*.** Body and wings yellowish; antenna brownish yellow, frons white at the sides; submarginal and marginal spots of the hindwing yellow. Dorsal edge of the harpe slightly or not at all dilated; central process either simple or ventrally denticulate at the base. Scent-scales shorter and broader than in the other species of this group, with the exception of *agesilaus*. Larva not known with certainty. Panama to South Brazil; the ♂♂ very common, often resting together with *protesilaus*, *agesilaus*, *glaucolaus*, etc., on damp sand or mud. — ***dolius* R. & J.** Band 1 of the forewing not prolonged to the hindmargin; margin of the hindwing more extended white than in the next subspecies; subbasal band of the underside of the hindwing not entering the basal cell. Dorsal edge of the harpe only very feebly dentate, scarcely at all dilated, central process not denticulate ventrally at the base. Panama and West coast of Colombia. —

***telesilaus*.** ***telesilaus* Fldr.** (16a). Band 1 of the forewing continued along the 3. submedian; subbasal band of the hindwing beneath entering the basal cell. Dorsal edge of the harpe dilated, denticulate, central process with dentate ridge ventrally at the base. Central Colombia to Guiana and Pará, distributed southwards to Bolivia, Paraguay and Rio Grande do Sul.

Thyastes-Group.

In the species of the densely scaled *thyastes*-group the hindwing has on the under surface a red or brown-yellow band, which runs about parallel with the outer margin and begins at the costal margin beyond the middle. In all the species the 1. subcostal anastomoses with the costa, which does not occur in the preceding groups.

***P. marchandi*.** Hindwing beneath with brown-yellow discal band. Markings of the upper surface yellow, both wings with yellow discal area and submarginal spots, the area of the forewing continued towards

the costa by several spots. Larva not known. Mexico to West Ecuador. — **marchandi** *Boisd.* (16b). The *marchandi*. brownish yellow discal band of the hindwing beneath usually curved anteriorly. Discal area of the upper surface of both wings deep dark yellow. Mexico to Honduras, in hilly country, in Guatemala common up to 2500 ft. — **panamensis** *Oberth.* The yellow colour on the whole paler than in the northern form, some- *panamensis*. times pale yellow, the submarginal spots between the 2. radial and the 2. median of the hindwing larger, the discal area of the forewing more deeply indented at the veins. Costa Rica to West Ecuador.

P. thyastes. Forewing with complete or interrupted yellow discal band and hindwing with large yellow discal area; underside of the hindwing with red discal line. Ecuador to Bolivia; Brazil. — **thyastinus** *thyastinus.* *Oberth.* The submarginal spots between the 2. and 3. radial of the forewing separated by a corresponding discal spot, discal band usually interrupted at the 3. radial, the 1. submarginal spot is absent or small. Eastern slopes of the Andes from North Ecuador to Central Peru, Upper Amazon. — **zoros** *R. & J.* Like the preceding; *zoros*. the 1. submarginal spot of the forewing sharply defined; the discal spot between 2. radial and 1. median usually truncate distally, the upper angle not rounded. South-East Peru and Bolivia. — **thyastes** *Drury thyastes.* (= *diaphorus* *Hbn.*) (16b). Paler yellow than the Andes forms; discal band of the forewing not interrupted, or only very slightly, the submarginal spot between the 2. and 3. radials quite close to the discal spot or partly merged together with it; the black discal area of the hindwing not entering the cell. Southern Brazil, only known from São Paulo to Rio Grande do Sul.

P. dioxippus *Hew.* (16c). Wings on the upper surface with common green-yellow triangular area; *dioxippus*. forewing with vestiges of costal bands; hindwing with 2 red spots at the anal angle. — Very common in Bogotá-collections; Valleys of the Cauca, Magdalena and Meta Rivers, at moderate elevations. ♀ not known.

P. lacandones. The discal area of the forewing extends costad to the lower angle of the cell or beyond it. Guatemala to Bolivia. ♀ not known. — **lacandones** *Bates* from Guatemala and Panama. Fore- *lacandones*. wing with 4 thin submarginal spots, discal area extending anteriorly beyond the 2. radial. — **diores** *R. & J.* *diores.* (16b). Forewing broader, with 5 submarginal spots which are larger than in the preceding subspecies, discal band not extending beyond the 2. radial, the subapical spot of the cell much smaller than in *lacandones*. Eastern slopes of the Andes of Ecuador, Peru and Bolivia.

P. calliste. Bands and spots of the wings pale yellow or greenish yellow, similarly arranged as in *dioxippus*; submarginal row of the forewing curved; hindwing with 2, rarely 3 red spots, and with 2 very large greenish yellow marginal spots from the 2. radial to the 1. median; underside of the hindwing with pale marginal band. ♀ not known to us. Mexico to Costa Rica. — **calliste** *Bates* (= *lorzae* *Boisd.*) (16b). *calliste*. The two outer cell-bands of the forewing clearly developed and the last but two more or less indicated, the discal area emarginate at the cell before the 2. median. Western Mexico, Guatemala and British Honduras. — **olbius** *R. & J.* Larger than the preceding form; also the outer cell-bands of the forewing suffused with *olbius*. black in the middle; discal band broader, the black marginal area on both wings consequently narrower than in *calliste*; submarginal line of the forewing only vestigial from the 1. median backwards. Costa Rica.

P. leucaspis. Frons entirely brownish black; abdomen yellowish beneath; the wings with common triangular green-yellow area; the brown marginal area with blackish lines parallel to the margin. ♀ not known. Colombia to Bolivia; a very common species in the Andes. — **lamis** *R. & J.* The posterior cell-spots of the *lamis*. forewing large, very distinct also beneath. Colombia. — **leucaspis** *Godt.* (16c). The cell-spots of the fore- *leucaspis*. wing smaller, usually only indicated beneath, the two outer posterior cell-spots more widely separated from one another. Eastern slopes of the Andes, from Ecuador to Bolivia.

Doliceon-Group.

The 7 following Papilios form the *doliceon*-group. In these species no red or yellow band is present on the under surface of the hindwing. In some species only the 1. subcostal of the forewing is confluent distally with the costa, whilst in others the 2. subcostal also anastomoses with it.

P. serville. Forewing with broad black cell-band, which runs obliquely from the costal margin to the marginal area, being united with the latter. In the forewing the 1. and 2. subcostal distally confluent with the costa, the 2. subcostal rarely free. ♀ not known. North Venezuela, Colombia to Bolivia. Common. — **acritus** *R. & J.* The spots on head and breast small, also the yellowish lateral stripe of the abdomen *acritus*. reduced, these markings sometimes absent; cell of the hindwing usually without blackish streaks. North Venezuela, East and Central Colombia. — **serville** *Godt.* (= *servillei* *Boisd.*, *boliviana* *Weeks*) (16c). The *serville*. spots on breast and head always present, abdomen with 2 yellowish stripes on each side, of which the upper one is broad; cell-streaks of the forewing distinct, the subapical area of the cell always shaded with brown; the pale patches before the margin of the hindwing, on the under surface, more distinct than in *acritus*. West Colombia and Ecuador to Bolivia.

P. columbus *Koll.* (= *hippodamus* *Fldr.*, *burtoni* *Reak.*) (16c). Very nearly allied to *serville*; the *columbus*. narrow green costal band of the forewing more oblique than in *serville*, marginal area of the forewing beneath more purplish white, the blackish lines in it and the yellowish streak on the underside of the

abdominal fold of the hindwing less distinct than in *serville*; the black distal area of the hindwing sometimes touches the cell, but does not enter it. Specimens with yellowish instead of deep red anal spot are abundant. *fulva* Oberth. ♀ similar to the ♂. Cordillera of Bogotá to the West coast of Colombia, North-West Ecuador; common; a ♀ in coll. H. J. ADAMS.

P. orabilis. Club of the antenna black; the black median band of the forewing does not extend to the marginal area, hindwing with long red anal spot, which reaches to the 2. median. ♀ not known. *orabilis*. Guatemala to West Colombia. — *orabilis* Bth. The oblique discal band of the hindwing not marked above. *isocharis*. Costa Rica, Panama and (doubtfully) Guatemala. — *isocharis* R. & J. (17a). Median band of the forewing always extending to the 2. median; the black marginal area of the hindwing broader than in *orabilis*, with an oblique spur pointing forwards, which corresponds to the posterior part of the discal band of the under surface. West Colombia.

P. salvini. *P. salvini* Bates (17b). The black bands very much reduced, a narrow band in the middle of the cell, not extending beyond the median vein; under surface glossy white; hindwing with black-brown discal band which runs almost straight from the costal margin to the red anal spot. 1. and 2. subcostals of the forewing distally confluent with the costa. ♀ and larva not known. — Guatemala, British Honduras and (doubtfully) Yucatan; most of the specimens in collections come from the woods in Northern Vera Paz, Guatemala.

P. callias. *P. callias* R. & J. (= *columbus* Hew. non Kollar) (17a). The short cell-band of the forewing much broader than in *salvini*, the discocellular band also short and broad, confluent with the marginal area at the lower angle of the cell; hindwing shorter than in the preceding species: the marginal tooth placed before the thin tail prolonged, thin. Hindwing beneath with black discal band, divided into two branches at the extremity of the cell; this band in the ♀ more distal, placed quite near to the marginal area, with which it is almost confluent. — East Ecuador, Peru and the Amazons.

P. dolicaon. Head and breast black, dotted with white. Black cell-band of the forewing oblique as in *callias*, but still broader than in that species, a macular band between the cell and apex of the wing. Hindwing rounded, with thin tail, beneath with forked discal band, the proximal branch of the fork running to the abdominal margin. The 1. subcostal anastomoses with the costa, 2. subcostal free as in *callias*. Larva not known. Colombia to Paraguay and South Brazil. — *hebrus* R. & J. The white subapical area of the cell of the forewing narrowed costad; hindwing more strongly rounded than in the other subspecies. Under surface of both wings purplish; the discal area of the forewing divided into spots by broad black vein-streaks; hindwing yellowish. Colombia: Magdalena Valley and Cordillera of Bogotá. — *deileon* Fldr. (17a). Marginal band of the hindwing beneath narrow below the 1. radial, at the 2. radial only 1—2 mm broad, the proximal branch of the discal band traversing the cell at the base of the 2. median, the greenish white apical spot of the cell much larger than the spot placed at its costal side. East Ecuador to Bolivia and Matto Grosso, and the Amazon downwards to Pará; according to FELDER also from "Bogotá", but his specimens may be from the East side of the Cordillera of Bogotá or from North-East Ecuador. — *tromes* R. & J. Green-white subapical area of the cell of the forewing above very faintly shaded with black; marginal band of the hindwing broad, the green-white spots placed at the apex of the cell between the 1. and 3. radials small; marginal band of the underside of the forewing below the 1. radial only about 1 mm broad; the proximal branch of the discal band of the hindwing placed somewhat distally to the base of the 2. median, green-white apical spot of the cell at most as long as the spot placed before it between the 2. subcostal and the 1. radial. North Venezuela. — *dolicaon* Cr. Marginal band of the forewing beneath at the 2. radial 3—5 mm broad in the ♂, somewhat narrower in the ♀; proximal edge of the marginal area of the hindwing above remote from the cell; proximal branch of the discal band of the hindwing beneath as in *tromes* distal to the base of the 2. median vein; the brownish yellow postdiscal spot between the 2. subcostal and 1. radial placed transversely to the veins. Orinoco; Guiana. — *deicoon* Fldr. The white subapical spots of the forewing large; the black marginal area of the hindwing narrower than in the other forms. Paraguay; Brazil, from Rio Grande do Sul to Goyaz.

P. iphitas. *P. iphitas* Hbn. (= *dolicaon* Godt. non Cramer) (17a). Similar to *dolicaon*; yellow, the black marginal area of the forewing narrower posteriorly; the oblique discal band of the hindwing on the upperside present from the black marginal area at least to the 2. subcostal. ♀ not known to us. — Brazil, in hilly country: Espirito Santo, Organ Mountains in the province of Rio de Janeiro, and Pernambuco.

2. Genus: **Euryades** Burm.

Frons with short hairs. Tibiae naked, not woolly, furnished with a few bristles; tarsi short. Antenna with ~~one~~ club and a row of sensory grooves at each side. Stalk of the subcostal fork of the forewing as long as the posterior branch (= 5. subcostal vein), 1. radial before the middle of the cell; basal cell of the hindwing from 2. subcostal vein very distal, branching from the cell at about the same height as the 2. median, apex of the cell rounded, the lower angle obtuse. The bipartite claspers of the ♂ not quite

closed together; the ♀ after copulation with so-called pouch. Larva on *Aristolochia*, and like the pupa, formed and coloured quite as in the *Aristolochia-Papilio*s of the *Papilio perrhebus* group. In these *Aristolochia-Papilio*s we find already a rudimentary pouch; in *Euryades* it is large, bilobate. — This genus is confined to the Rio Paraná (with its tributaries), Argentina and Paraguay; 2 species, which are both sexually dimorphic.

E. duponcheli Luc. (17b). Tailed. ♂ velvety black, with a yellow band of large patches in the middle and on the hindwing also 2 rows of red spots, of which the submarginal row is only more or less indicated above. ♀ yellow-brown, black distally and in the cell of the forewing, the macular band above only indicated by 2 subcostal patches, which are situated on the forewing; the red spots of the hindwing above vivid red; under surface for the most part grey-yellow. — From Buenos Aires northward, commonest in North-West Argentina.

E. corethrus Boisd. (17b, c). Tailless. ♂ much paler than in *duponcheli*, semitransparent; hindwing also above with a band of yellow spots outside the red discal spots. ♀ likewise paler than in the preceding species, the margin more narrowly black, the very pale red submarginal spots of the hindwing large, the discal row on the contrary replaced by black spots, only the last always dotted with reddish grey, but often also the first and sometimes the next two as well. — Not quite so common as the preceding species and not so widely distributed; more in the neighbourhood of the Rio Paraná and Rio Paraguay.

3. Genus: **Baronia** Salv.

Antenna short, with broad club. Legs likewise very short, femora with long hairs, before the extremity with some stiff bristles, tibiae rough with bristles; 1. segment of the tarsus about $\frac{1}{3}$ as long as the tibia; the spur of the foretibia reaching to $\frac{3}{4}$. Forewing rather narrow, 1. and 2. subcostals close together, the 1. confluent with the costa and partly also with the 2. subcostal, the 3. absent, the 4. and 5. rather long stalked; 1. radial arising from the cell; hindmargin of the cell almost straight, no median spur; hindwing rounded, with large basal cell, the 1. subcostal, which closes it distally, very weak; precostal forked, 2. subcostal branching off much more distally from the cell than the 2. median. Scales of the wings rounded. — The only known species belongs in the neighbourhood of *Parnassius*. — Guerrero, West Mexico.

B. brevicornis Salv. (17c). Mr. O. T. BARON discovered this peculiar insect in the neighbourhood of the town of Chilpancingo, recently destroyed by an earthquake, where the butterflies were flying in June and July at a height of 4500 ft. He only took 5 specimens, which are in the collections of GODMAN, ROTHSCHILD and the California Academy. Blackish brown, with pale yellow markings; all the spots of the hindwing beneath are silvery white as well as the apical and submarginal spots of the forewing. ♀ somewhat larger than the ♂, the light markings more extended.

4. Genus: **Parnassius** Latr.

For the general characters the reader is referred to the descriptions in Part I, Vol. I, p. 19. A special distinguishing feature of the genus is the absence of the hindmarginal vein in the hindwing and of the transverse vein present in the genus *Papilio* s. str. between median and submedian near the base of the forewing. A striking characteristic moreover is the pouch (Abdominaltasche, poche cornée) of the impregnated female, mentioned in *Euryades*, which besides is only found in a few of the allied genera, namely in *Eurygus* Boid., *Luchdorfia* Crüg., also occurring in a single species of the genus *Papilio* (*P. proneus* Hbn.) (JORDAN) and in the whole family of Acraeidae. Exhaustive observations and investigations have been devoted to the nature of this appendage. It is not an organ of the body, but a product of the insect itself, and is produced during the copulation of the sexes in this way, that the ♂ ejects from a gland at the anal extremity a secretion which hardens very quickly, and in the moment of ejection with the assistance of a special membranous organ (peraplast) assumes a definite form and is attached to the abdomen of the ♀ (SIEBOLD, THOMSON, SCUDDER). This product is therefore an independent creation of the organs of copulation, but its form appears to depend on the peculiar structure of these, and is therefore to be regarded as a valuable means of help in the differentiation of the species and in arranging them into natural groups. Concerning the purpose of this peculiar appendage nothing is known with certainty. One would suppose that it plays some part in oviposition, but this is contradicted by THOMSON's observations in breeding *Parnassius apollo* L. in the Insectarium of the Zoological Gardens in London; he is of the opinion that the pouch is without any utility after copulation. The fact that ♀♀ of *Parnassius* species have been taken, in the pouch of which a loose egg was found, permits the supposition that the insect carries this with it until it has found a suitable place for laying.

The *Parnassius* forms are inhabitants of the mountains in the Northern temperate zone, entirely wanting in the tropics, subtropics and the Southern temperate zone of America, even in those heights of the Cordillera which would suit their conditions of life. Their area of distribution is confined to a Western strip of North America. As Southern limit about 35° N. Lat. may be taken, in the East the principal chain

of the Rocky Mountains forming the boundary line, whilst northwards they extend in Alaska as far as the polar circle; in the mountains they ascend to about 4000 m (14 000 English ft.).

America possesses representatives of only two of the groups into which *Parnassius* can be naturally divided according to the abdominal pouch, of which *P. thor*, *clodius* and the allied forms are to be classified with the Palaearctic *clarius*-group with whitish, elongated, vesicular pouch, whilst the *smintheus* forms belong to the *apollo*-group, in which the pouch is small, dark brown, carinate beneath, and pointed like a leaf.

P. eversmanni Mén. (vol. I, 10g) is represented in Alaska by a form with narrowed bands, to which *thor* is to be applied the name of **thor** H. Edw., proposed for the ♀. Ground-colour of the ♂ yellow as in the Asiatic form, markings of the wings agreeing rather closely with those of the ♀ of *P. clodius*, but the bands and spots narrower, and the discal band outside the cell somewhat further removed from it, less irregular and more sharply defined; the hindwing without submarginal crescents, only 2 indistinct patches near the disc, the basal and hindmarginal area blackish, at the usual places 2 ocelli filled in with red, the posterior one connected with a black anal spot by a narrow band-like shading. ♀ whitish with broadened bands, the anal spot on the hindwing with two red dots, its connection with the posterior ocellus broader, near the outer margin a row of sharp black lunules. Only 3 specimens (1 ♂, 2 ♀♀) known: at the upper course of the Yucon River, June.

clodius. **P. clodius** Mén. (17d) is very nearly allied to *eversmanni*. Ground-colour white, only in the ♀ the short costal band placed outside the cell connected with the hindmarginal spot by an irregular dusty band, the glossy submarginal band of the forewing sharp but narrow, the ♂ with small, the ♀ with larger, crescent-shaped submarginal spots on the hindwing; on the latter the anal spot mostly centred with red. Coast district of Oregon and California, southwards to about San Francisco. The biology is still unknown. It is suspected that Viola is the food-plant, perhaps also Sedum and possibly Vaccinium or Rubus (dewberry) (WRIGHT). Is commonly (even in recent works) confused with the specifically different *P. clarius* Eversm. from Asia, or this name is applied to the mountain form of the species (see further below). — Ab. **altaurus** Dyar is an aberration from the name-typical form with yellowish instead of red anal spots. — In the Northern adjoining districts occurs a race, larger on the average, with much broadened marginal pattern on the forewing. Marginal and submarginal bands are merged into a broad stripe, through the middle of which runs only one row of small white crescents. This form has been introduced as **claudianus** Stich. (17c). In the ♀ the black band-pattern is less intensive but broader, the connection of the costal spot and hindmarginal spot only shadowed as a narrow streak, on the hindwing very large marginal lunules, the anal spot without red dot. Washington Ter., Vancouver Island, types No. 27918 to 27921 in the Kgl. Zool. Museum Berlin. There are transitions to the typical form. — **baldur** H. W. Edw. (17e) occurs in the mountains to the East of the district of the principal form. This is distinguished by reduced and less sharp markings. In the ♂ the hindmarginal spot is mostly absent on the forewing and the anal spot on the hindwing; the posterior ocellus is reduced as a rule; the ♀ has no submarginal crescents on the hindwing, the anal spot is rarely centred with red; in both sexes the white dusting very thin, somewhat transparent. Sierra Nevada, about from the Emigrant to the Truckee Pass; also reported from the Wahsatch Mountains (Utah). Varies rather considerably, and forms on the one hand transitions to the coast form, on the other hand there occurs a further reduction of the pattern. Specimens with point-like, reduced posterior ocellus are not rare: ab. **lusca** Stich. (17e); or those in which the two ocelli only remain as vestiges: ab. **menetriesii** H. Edw. (17e). On the other hand ab. **lorquini** Oberth., in which the ocelli are entirely absent, occurs only sparingly. In the type of this form in addition all the black markings also are effaced except two narrow oblong spots in the middle and at the end of the cell of the forewing and some blackish dusting at the hindmargin of the hindwing. — A further race from Montana, **gallatinus** Stich., is distinguished by the band-pattern of the ♂ being in general weakly marked, while on the contrary there is a complete discal band outside the cell, as in the ♀ of the typical form; hindwing without anal spot and with small ocelli; the ♀ is more strongly marked, partly dusted over with black, the forewing with broader submarginal band, on the hindwing the submarginal lunulus and the anal spot strongly developed. Gallatin County (ELROD).

smintheus. **P. smintheus** Doubl. is an American representative of the Asiatic *P. phoebus* F. Ground-colour chalk-white, forewing with the peculiar black spots of the *apollo*-group, in the typical form an incomplete submarginal band on the forewing, the costal spot faintly centred with red, the transparent border narrow at the outer margin, commonly only extending to the middle of the wing, interrupted by white marginal spots, the white fringes spotted with black at the extremities of the veins; hindwing with 2 small ocelli, filled in with red, hindmarginal spot as a rule weakly indicated. ♀ as a rule somewhat larger, forewing with larger costal spots, filled in with red, strong hindmarginal spot and broader margin, hindwing with larger ocelli, 1—2 anal spots filled in with red and a row of submarginal crescent spots. Extraordinarily variable in size and markings, in the ♂ the submarginal band of the forewing sometimes more strongly developed, the glassy border very variously developed, the white patches of the same sometimes more

weakly, sometimes more strongly expressed, occasionally a stronger black spot in the hindmarginal area, the costal spots also quite black, more copiously dotted with red or white; on the hindwing the anal spot in individual instances more distinct and near the margin sometimes some blackish spots. In the ♀, particularly those from high lying localities, more copious black marking and partial darkening of the white ground-colour are of no uncommon occurrence, also in both sexes individuals often occur with yellowish instead of red ocelli, which are usually referred to *behrii* (see further below). But this name must be reserved for the Western race of the species. Specimens without red on the upper surface, in which even the ocelli of the hindwing are reduced to black spots, are usually called ab. *sedakovii* Mén. This is, however, an Asiatic form of *P. phoebus* F. and the name has been replaced by ab. **mendica** Stich. *mendica.*

The egg is semispherical, somewhat depressed at the top, the upper surface thickly granulated, the colour ivory white with a faint greenish tint. Development variable, some eggs yield the larvae in the same year, others hibernate. The young larva is nearly cylindrical, of black colour, the body covered with small hairy tubercles. When fullgrown it attains a length of 23—25 mm (0.9—1.1 inch), the ground-colour is then black-brown, brown on the underside and the legs, the body covered with short stiff hairs and marked with 4 rows of yellow, sometimes white spots; it has a fork-shaped, eversible yellowish gland in the neck; the head is broad, with impressed suture, of black colour. Pupa cylindrical, stout, about 15 mm (0.6 inch) long, the upper surface finely granulated, of yellow-brown colour with greenish reflection. When the larva is about to pupate it draws a leaf or several leaves together into a sort of cocoon by some silken threads, but pupae have also been found on the ground under pieces of wood without a trace of a cocoon. Duration of the pupal stage unknown. The time of flight of the butterflies lasts from May to September, but appears to depend on the temperature and other climatic conditions and the principal time of emergence is the month of July (COURTIS). The oviposition seems to be irregular and regardless of place, and it is left for the newly-emerged larva to find its food-plant: it was observed that the eggs were laid on the stalks of grass or other plants (Composites, Artemisia, etc.), or even on stems or on the ground itself, but always near to this. Various opinions have been advanced as to the food-plant; thus, among others, BRUCE suspected it was *Castelleia integra*, and also suggested *Saxifraga*, later he assigned *Sedum stenopetalum* as the true food-plant; W. H. EDWARDS reared the larvae on *Sedum ternatum*, but they also accepted other species of *Sedum*. By night they live concealed in secure hiding-places on the ground, not coming out until the sun shines; they are commonly attacked by parasites (Tachinids). The imagoes are common where they occur, but are difficult to catch, not only on account of the natural obstacles of the ground, but also on account of their rapid and high flight. Newly emerged males emit, particularly at the time of copulation, a peculiar, pungent and disagreeable odour, which reminds one of mice (W. H. EDWARDS, WRIGHT, REAKIRT, FRUHSTORFER, etc.). Habitat of the typical race: the Rocky Mountains in Wyoming and Colorado.

The species is very variable, but according to our experience with the European and Asiatic species the formation of races in certain restricted localities is to be assumed as in the highest degree probable. These races nevertheless intergrade with one another and in the region of flight of the one form are found individuals with characteristics of the others and vice versa, so that the characters assigned to the following forms are only to be taken in a very general sense. In doubtful cases the locality of the insect must settle the question. — As **hermodur** H. Edw. only a strongly darkened form of the ♂ is usually *hermodur.* described. The original is recorded from the Southern part of the distribution-area. ♂♂ (17e) from that district for the most part differ in that the glossy border of the forewing is not interrupted by white spots at the margin, the submarginal band is only very weakly developed, and the costal spots are occasionally much reduced; ♀♀ occur in a more or less darkened form. The name may be applied collectively to the Southern race. South Colorado, Northern New Mexico. — In **sayii** W. H. Edw. (17d) the ♂♂ are usually *sayii* larger, with larger deep red ocelli, and otherwise approach the Asiatic *intermedius* Mén.; in the ♀♀ as a rule a more copious sprinkling with black scales is noticeable, so that they agree in this with the ♀♀ of the previous form; the costal spots of the forewing are large and quite filled in with red, the glossy border broad, only separated from the submarginal band by a row of luniform spots, the submarginal crescents of the hindwing especially strongly marked and merged together into a broad band. Montana, Judith Mountains. — From the Northern parts of the Rocky Mountains there is a smaller form described as **nanus** *nanus.* Neumoeg. The type-specimen of this resembles the ab. *mendica*; in the ♂ the red colour is entirely absent on the upper surface of both wings, the greater part of the outer margin is glassy grey, on the hindwing only the hindmarginal area is blackish and in the disc there is a black spot instead of the ocellus. The ♀ is similar to that of *hermodur*, darkly dusted, with 2 costal spots filled in with red, hindwing with glassy grey border, the red ocelli with white pupils, all the black markings vivid. British Columbia and Montana. — In the West the species is represented by **behrii** W. H. Edw. (17d): a rather large form, in which the ♂ *behrii.* usually has somewhat longer wings, the submarginal band is marked anteriorly by sharp black luniform spots, which become obsolete posteriorly, the anterior ones of the costal spots usually centred with red, the glossy border is confined to the anterior half, narrowed and so restricted by the white marginal spots that it only remains as a row of blackish wedge-shaped spots; ocelli of the hindwing small. The red-

yellow colouring of the ocelli and the development of small submarginal spots on the hindwing are given as special characteristics, but these features are not constant. The ♀♀ as a rule have the costal spots on the forewing strongly filled in with red, a strongly marked submarginal band, the disc more or less dusted with black, on the hindwing the submarginal lunules are confluent as a sort of band and there are grey spots at the margin itself. In aspect on the whole like *sayii*-♀ or a lighter *hermodur*-♀. California (Sierra Nevada), Utah. Ab. **niger** Wright is an individual form of this local variety corresponding to the ab. *mendica*; this has on the forewing only two black cell-spots, an insignificant costal spot, traces of a submarginal band, the outer margin has no glossy border, both ocelli of the hindwing are reduced to black points. Summit, South California, 2600 m. Another large form of the species is **magnus** Wright, which is only slightly different from *behrii* in that the submarginal band of the forewing is almost complete but less sharply marked, and the glassy border is broader, extending to the hinder angle and less restricted by white marginal spots; hindwing in the type-specimen without anal and submarginal spots, the anterior ocellus very small, the posterior one also only moderately large, the latter with white pupil, the former entirely red; ♀ with costal spots copiously filled in with red and red-dotted hindmarginal spot on the forewing, blackish shading in the disc, border broadly glassy grey; ocelli of the hindwing large, the posterior one with white pupil, submarginal band not extra strongly marked, but the margin itself glassy. Enderby, British Columbia. -- The most northerly representative of the species is **apricatus** Stch. (17d); distinguished by the roundish shape of the wings and very strong black spotting; on the forewing the costal spots changed to a short band, in which there is an almost square red spot anteriorly; submarginal band sharply marked, a large black spot in the hindmarginal area; on the hindwing the hindmarginal area broadly black, a small anal spot, the ocelli large and filled in with deep red, in the posterior one some white dusting. ♀ similarly marked to the ♂, somewhat dusted over with blackish, submarginal band of the forewing and the glossy border broader and complete, hindwing with broader submarginal band and blackish glossy border. In general very similar to the Asiatic *phoebus* forms. Kadiak Island (Alaska).

By older authors (MORRIS, BOISDUVAL) *P. nomion* Fisch. d. W. is recorded from the Rocky Mountains and California, according to more recent accounts (DYAR, WRIGHT) the species occurs in Alaska. However, a more certain confirmation of these records is wanting, and there appears to be a confusion with a form of *smintheus*, especially as regards the records of earlier date.

Alphabetical List

with references to the original descriptions of the forms of the American Papilionidae.

* signifies that the form is also figured in the place cited.

2. Family: **Pieridae**, Whites.

In comparison with the other faunistic regions, America shows a great abundance of genera. Of the 40 odd genera of Pierids represented in this region 28 have no representatives in other regions, whilst of the 23 Palaearctic genera only 12, of the 14 Indo-Australian only 4 and of the 13 African genera also only 4 are not represented in other faunistic regions. The American Pierid-fauna has consequently quite a character of its own, so much the more as several of the endemic genera are very rich in species and the species for the most part show a great abundance of individuals. Of the 28 American genera only one (*Neophasia*) is confined to North America (accepting the Tropic of Cancer as its southern boundary), and even this wears the garb of allied Palaearctic and Nearctic members of this family, whilst the remaining 27 genera are indigenous to South America. Of these again 3 genera inhabit exclusively the high mountain ranges, 1 genus (*Tatochila*) is principally met with in the southernmost part of the continent and 2 genera (*Sphaenogona* and *Enantia*) are island-dwellers. North America is relatively poor in species of Pierids, since it only possesses about 50, the Palaearctic Region on the contrary showing about three times as many. The whole of the genera which are represented in North America, but yet are not peculiar to this region, occur also in the Palaearctic Region, with one exception (*Nathalis*).

Although the great majority of the American species only belong to the medium-sized butterflies, yet the genera *Catopsilia*, *Amyntia* and *Gonepteryx* show also species which are not inferior in size to the largest forms of this family from other regions. Though there is no large number of species in America which equal in the beauty of the colour of the wings especially Oriental Pierids, the American Region is not wanting in strikingly beautiful forms.

Whilst the other faunistic regions can only show a very small number of Pierid-species which pass as so-called mimics (species of *Pareronia*), tropical and subtropical America possesses a great abundance of them, as for example numerous species of the genera *Dismorphia*, *Pereute* and *Archonias*, which show so-called mimicry in both sexes, whilst in the genus *Perrhybris* only the ♀♀ of some species exhibit this convergent development, the ♂♂ of only a few species having on the underside indications of a resemblance to protected species of other families. Not only these, however, but also species of the genera *Pieris*, *Tatochila*, *Dismorphia*, *Pereute*, *Hesperocharis*, *Appias*, *Terias*, *Catopsilia*, *Euchloë*, *Anthocharis* etc., show striking sexual dimorphism. Seasonal forms occur in North America much as in the Palaearctic Region, in the tropical part of South America on the contrary they are practically non-existent on account of the want of seasonal changes. Sharply defined local forms could only be developed to a very small extent owing to the geographical conditions of the region; on the other hand the high mountain-ranges of South America show a fauna of their own, whilst the large steppe-district in the most southerly part has some forms in common with the south of North America as well as a few endemic ones.

Most of the American Pierids are not rare, many are even very common, although in comparison with the richness in species and individuals of some other families of Lepidoptera they are not so conspicuous as in the Palaearctic Region. Frequently large swarms of different species have been observed, even of such as are by no means of common occurrence. Thus among others at the beginning of October 1874 on the Bermuda Islands an immense swarm of *Terias lisa* was observed, thousands of which fell victims to the birds; these small butterflies flew further westward and had to travel about 600 miles to the next resting-place (Cape Hatteras). The larvae of some species of Pierids on account of their abundant occurrence do serious damage to field and garden plants both in North and in tropical America; the north of the United States has a dangerous enemy to the pine-forests in *Neophasia menapia*, and *Pieris rapae*, which was introduced into North America about 1860, has increased to such an extent that it does even greater damage there than in its original habitat, the Palaearctic Region.

In general the Pierids are of medium size, but some species are large butterflies. The main character of the pattern consists in white colouring with dark, blackish stripes and spots; yet there are also, particularly among the Exotics, a large number of species which in the size of the wings and the gorgeousness of the colours equal the most beautiful forms of other families of Lepidoptera. In these brightly coloured species the contrast between upper and under surface is very striking. Whilst a large part of the species have on the whole the characteristic marking of the family (white-black), there are among the tropical species also many with yellow, blue, red or black ground-colour on the upperside, and on the other hand some with white upper, but variegated under surface. Thus the South American *Pereute*-species, with their black ground-colour and red bands on the forewing both above and beneath, completely belie their Pierid nature, and *Archonias critias* and allied species resemble the species of the *aeneas*-group of the South American Papilios.

Sexual dimorphism is well developed in many species from all the faunistic regions, seasonal dimorphism naturally only in those species which inhabit districts with sharply marked seasonal changes.

Antennae of varying lengths, e. g. in *Leptidia* rather short, in the South American genus *Leptophobia* on the contrary very long, the club clearly defined or gradually thickened. Forelegs normally developed, therefore capable of use, with bifid claws. Proboscis well developed. The butterflies feed at flowers and moist places on the ground. Palpi well developed, but variable. Male secondary sexual characters (seent-organs) occur in the species of several genera, e. g. in *Colias* as a specially scaled spot on the hindwing, in *Catopsilia* as broad patches of thick scaling, in *Appias* (*Tachyris*) as a pencil on the underside of the abdomen, in *Dismorphia* as large chalky spots of scales on the under surface of the forewing, from which the scent is given off by rubbing against the strongly widened anterior part of the hindwing. Other species (e. g. *Pieris brassicae* and its allies) possess feather-brush scales (Aurivillius), which are extended over the greater part of the wing and apparently are the cause of the suppression of the dark markings in the $\sigma\sigma$, and other species again (e. g. *Pieris buniæ* from South America) broad stripes of thick chalky scales along the veins.

The Pierids — like most *Rhopalocera* — are sun-loving insects, but, in common with a few other butterflies (mostly Satyrids), nevertheless extend into the Arctic, Antarctic and Alpine regions, without losing anything in brilliancy of colouring in comparison with allied genera from warmer districts. The high mountains of South America and the south-eastern boundary of the Palaearctic Region each even possess two genera quite peculiar to themselves, namely the former *Phulia* with about six species and *Andina* with one *Colias*-like species, and the latter *Mesapia* and *Baltia*, of which the last-named is very nearly allied to *Phulia*.

The Pierids are as a rule moderate fliers, but some also fly unusually swiftly (*Appias*) and others so slowly that they can be caught with the hand when on the wing (*Leucidia*). They occur in one or more generations.

The intellect is obviously very different in the various Pierids, for whilst for instance *Pieris brassicae* and the *Colias*-species are capable of very quickly recognising danger when pursued by the collector, this is much less to be observed in others (*Pieris napi* and *rapae*).

The swarming and migration of the butterflies, already referred to, have been regarded as nuptial flights; *Catopsilias* and *Pieris brassicae* especially have been observed to form such swarms.

The eggs are oblong, are laid in an upright position singly or in clusters, sometimes in large numbers, on the underside of the leaves of the food-plant, and are of different colours.

The larvae are cylindrical, mostly of green or greenish ground-colour with light longitudinal stripes and short hairs; none have yet been observed with spiny or such like processes. They do not possess the fork on the neck characteristic of the Papilionid larvae, which is said to afford the insects protection from their enemies by the emission of an unpleasant odour, neither has it been proved that — like many Papilionid larvae — they acquire poisonous or at least nauseous properties from their food; nevertheless they are not only unpalatable to birds, but it has also been observed that fowls which had been fed on these larvae died, evidently in consequence of a poison contained in their bodies. They live on various shrubs and herbaceous plants, such as Papilionaceae, Mimosas, Crucifers and Caparideae.

The pupa is attached to plants etc., by its abdomen, in an upright or hanging position, and is held in this position by a girth. Some are of very singular form, such as the tube-shaped pupae of the species of *Anthocharis*; but in general the Pierid pupae show few differences. The Palaearctic *Zegris eupheme* — and probably not only the other Palaearctic species (*Z. fausti*), but also the North American *Z. olympia* — pupates in a rather thick cocoon, but still possesses a remnant of the girth. This characteristic (recalling the »Bombycids») is much more pronounced in the Mexican *Eucheira socialis*. The larvae of this species are gregarious and go out at night in a procession to feed. The common web hangs down from a bough, in the form of a pouch; the pupae are fastened in it head downwards (J. ALEMAN).

Some of the Pierids hibernate as pupae, some as larvae, and some — e. g. the Palaearctic *Gonepteryx*-species — as butterflies.

In the Palaearctic and Nearctic Regions the Pierids preponderate by their great number of individuals, in the tropics they are more restricted. Some Pierids have a very extensive range, thus *Pieris rapae* and *napi* occur in the whole Palaearctic and the Nearctic Regions, *Belenois mesentina* in the southern Palaearctic, Indian and African Regions.

Although — as already mentioned — the larvae do not appear to absorb poison from their food-plants, the butterflies are very little pursued by the birds, and are therefore apparently unpalatable to them or at least not much appreciated.

Several fossil Pierids have been found, which do not differ in size from the present-day species.

1. Genus: **Neophasia** Behr.

This genus is nearly allied to the Palaearctic *Aporia Hbn.* It differs principally in the direction of the precostal, which is not straight, but curved slightly inwards, the longer and slenderer palpi and the more distinctly clubbed antennae. The costal of the forewing only extends a little beyond the middle of the costal margin, the subcostal is four-branched with two branches before the closing nervure of the median cell, the third and fourth branches form a short fork and the third runs to the apex. The upper radial is coincident with the subcostal almost to one-half, hence the upper discocellular is wanting. The middle and lower discocellulars are about equal in length, the former is curved inwards, the latter is straight and closes the middle cell, joining the third median*) in an acute angle at its bend. The middle cell of the fore- as well as of the hindwing is rather narrow. The upper and middle discocellulars of the hindwing are about equal in length, and form together an almost straight line, the lower discocellular is longer, weaker, and meets the third median vein at the bend. Two purely North American species belong to this genus.

N. menapia Fldr. (= tau Scudder, ninonia B.) (18a) is white above and beneath, thinly scaled, *menapia* therefore somewhat transparent, the forewing has black markings at the apex and the anterior part of the distal margin, with white subapical spots, the costal margin is broadly black to the apex of the cell, also the discocellulars, the rest of the costal margin narrowly black. Hindwing almost without markings. On the similarly marked under surface of the forewing the black markings are paler, the veins of the dirty-white hindwing are black, there is also a submarginal band of the same colour. The ♀ has on the upperside paler black markings, some submarginal markings, and sometimes on the underside small red spots at the distal margin of the hindwing. — Egg flask-shaped, fluted at the sides. Full-grown larva about 25 mm. (1 inch) long, head cylindrical, abdomen terminating in two short tails, dark green with a broad white band at each side and a narrow white band on the back, abdominal legs black, thoracic legs greenish yellow. Pupa dark green, striped with white, similar to the *Colias*-pupae, but somewhat more slender. Larva on various conifers, sometimes so abundant as to cause considerable damage. In the north-west of the United States.

N. terlooii Behr (= epyaxa Poling, Archonias lyceas Skinner) (18a) is very similar in pattern to *terlooii*. *menapia*, but the black markings are more extended; the ♂ has white, the ♀ red-brown ground-colour. The larva lives in a common web on *Arbutus*. California. — **princetonia** Poling, from Illinois, is probably *princetonia*. only a form of *terlooii*. In the ♂ both sides of the hindwing are sprinkled with pale red at the margin, the ♀ is deeper red beneath than above, and the veins are more broadly edged with black than in the ♀ of *menapia*. — From lack of material I have not been able to decide with certainty whether this species belongs to this genus, but the agreement of the markings with *menapia* suggests a *Neophasia*.

2. Genus: **Eucheira** Westw.

Although this genus differs essentially from the preceding in the neurulation, yet it is closely allied to it in the life-history of the larva. The larvae live gregariously in a web, go out at night in a procession to feed, and pupate in the web with the head downwards. The subcostal of the forewing is entirely free, hence the cell is closed by three discocellulars. The cell is very narrow and long. Only one species.

E. socialis Westw. (18a), from Mexico, is a smoky grey butterfly with a white central macular band; *socialis*. the ♂ has in addition more distinct white submarginal spots on the upper and under surface of both wings.

3. Genus: **Tatochila** Bth.

This genus is almost confined to the southern part of South America and is closely allied to the following genus, *Pieris*; it differs from this in the shorter middle discocellular and the almost straight lower discocellular of the forewing, but principally in the uniform character of the markings. The species of this genus appear to occur only in one generation. The butterflies fly from November to April.

T. volxemi Capr. (= ahamantis Berg) (18a). Upper and under surface of the ♂ white with a *volxemi*. large black spot on the discocellulars of the forewing and slight blackish markings at the apex of the forewing above and beneath. ♂ similar to the ♀ of *theodice* Bl., but the marginal markings somewhat narrower, the submarginal markings on the contrary somewhat broader, also a black stripe in the cell of the hindwing. — Argentina.

*) What the author calls the „third median“ is really the third radial, there being three radial and two median branches in the butterfly-wing. — Transl.

autodice. **T. autodice** Hbn. (= demodice Stgr.) (18b), from the most southerly part of Brazil (Rio Grande do Sul, Argentina, Uruguay, Chile and Bolivia (3—4000 m), is differentiated from the following species chiefly by the yellowish red border of the eyes; markings and colouring are stronger on the underside. — The pupa, found by Dr. SERTZ in Buenos Aires, is somewhat smaller than the pupa of *Pieris brassicae*, yellowish, with a number of minute dark spots, the spiracles appear as larger dark spots and there are similar dots also on the dorsum, the wing-cases are white, with a large dark spot at the discocellulars of the forewing, larger dark spots at the distal margin and numerous minute dark spots on the rest of the wings, the cases of the legs, palpi and eyes, at well as the thorax, are likewise dark (black-brown). The butterfly emerged on 22. February. The larva is apparently not yet known.

mercedis. **T. mercedis** Eschsch. (= polydice Bl., autodice Kirby, autodice Eluc.) (18b), from Chile, differs from *autodice*, in addition to the previously mentioned characteristics, in the purer white upper surface, the weakly marked under surface and the entire absence of the elliptical marking at the costal margin of the hindwing beneath. The ♀ have a more or less developed streak-shaped black spot at the inner margin of the forewing above.

theodice. **T. theodice** Bdv. (= blanchardii Btlr.) (18c), from Patagonia, Peru and Chile, is cream-white above in the ♂, light yellow in the ♀, particularly on the hindwing; it is the most distinct species in the genus. —

gymnodice. **gymnodice** Stgr., from Punta Arenas (Tierra del Fuego), is probably a local form. Ground-colour of the ♂ pure white, the black markings somewhat narrower, underside of the hindwing without saffron-yellow stripes, only the basal part of the costal margin sulphur-yellow and a similarly coloured stripe at the apex. The ♀ has likewise narrower, but sharper black markings, the arrow-like spots on both wings are sharper and are connected. — Larva: head grey and covered with very fine, short hairs, body grey, with broad yellow subdorsal lines and a lateral row of small orange-red spots, and with raised black dots, sparsely scattered over the whole body, each with a very short, fine hair, ventral legs and underside of the body dark greenish yellow with small black spots, thoracic legs black. Food-plant: *Tropeolum*. Larva full-fed end of November (A. G. BUTLER). Flies from December to April.

argyrodice. **T. argyrodice** Stgr. (18a) is only known in the female. This species is well characterised by the grey ground-colouring and the sharply defined tear-shaped yellow spots of the under surface. South coast of Tierra del Fuego (Uschuaia).

microdice. **T. microdice** Bl. (= xanthodice Mab.), from Chile and Patagonia, is smaller and with less markings, also beneath a paler colour than **macrodice** Stgr. (18c, d), from Bolivia. — **sterodice** Stgr., from the east coast of Tierra del Fuego, is differentiated from this latter by a complete absence of yellow markings on the under surface, it is also white, almost without markings on the upper surface of the ♂, which is strongly glossy in the basal half. The ♀ has not a trace of yellow on the upper surface, whilst the markings are similar to those of the ♀ of *microdice*. — **arctodice** Stgr. occurs in Colombia and Ecuador. This form is very strongly marked with black, especially in the female; the upper surface of the ♀♀ is principally brown-black (with yellow spots).

pyrrhomma. **T. pyrrhomma** spec. nov. (18d), from Peru (Huancabamba, 3000 m), may be regarded as a distinct species on account of several important differences. The eyes are broadly (more broadly than in *autodice*) edged with fiery red-yellow, the black stripe at the costal margin of the forewing above extends to the base, the black spot on the discocellulars is distinctly smaller, the black marginal and submarginal markings are less developed, the latter almost square, the upper surface of the hindwing entirely without markings and strongly yellowish on account of the yellow colour of the under surface shining through. On the underside the veins are more broadly white, their margins more broadly grey-black than in *microdice*, the lower discocellular of the hindwing without white spot, the grey-black stripe in the cell very narrow and forked distally, besides the very sharply defined and broader saffron-yellow stripe at the costal margin there is also a similar one between the submedian and the first median. The under surface of the forewing is white, the veins are very finely black, those in the apex sharply white and very narrowly edged with black, the black spot at the end of the cell is small, the sulphur-yellow colouring of the apex reaches to the second median, and submarginal markings are completely wanting on both wings. ♂ unknown.

xanthodice. **T. xanthodice** Luc. (18d), from Venezuela, Colombia, Ecuador, Peru, Bolivia and Argentina, differs from *microdice* and *argyrodice* on the under surface chiefly in the saffron-yellow stripes between the veins of the hindwing, from *microdice* also in the absence of the white spot on the discocellulars on the underside of the hindwing. On the under surface the apex of the forewing has saffron-yellow stripes and the anterior veins are sharply edged with black to the apex of the cell.

demodice. **T. demodice** Bl., from Chile, South Patagonia and Tierra del Fuego, is distinguished from the following form by the absence of the arrow-spots on both wings. It must be noticed that according to

BLANCHARD'S insufficient description the name *demodice* cannot be employed with certainty for this species. I have seen no specimens which agree with this description, which may be translated thus: "Wings of the above white, of the ♀ yellow-blackish, in both sexes marginal spots, a row of arrow-spots and a black discoidal half-band; beneath the forewing yellowish at the apex, the hindwing entirely yellow, veins margined with black, gold-yellow lines — 20—21 lines." — **sagittata** *form. nov., spec. nov.?* (18e), from Peru (Huancabamba, 3000 m.), differs from this supposed *demodice* by the markings of the hindwing (shown in the figure), and further by the presence of four black submarginal arrow-spots on the forewing beneath, as well as by the colouring and pattern of the underside of the hindwing. The latter has a light yellow ground-colour, the veins themselves are very narrowly light, but edged with blackish about as broadly as in *orthodice*, there is a similar stripe in the cell, which shows no small white spot on the discocellular, between all the veins are saffron-yellow stripes and at the distal margin four very pointed blackish arrow-spots; at the distal margin there is an almost uninterrupted fine black marginal line, such as occurs in no other species of this genus. Underside of the forewing white, the veins becoming more broadly black towards the margin, the discocellulars not broadly margined with black, four submarginal arrow-spots, apex of both wings light yellow. ♀ unknown.

T. stigmadice *Stgr.*, from Bolivia (Cocapata, 3500 m.), differs from *immaculata* here figured by the *stigmadice*. much broader black spot on the discocellular and by the presence of 4—5 triangular black submarginal spots on the forewing and 2—5 of such spots on the hindwing, as well as the saffron-yellow colouring of the hindwing. — In **immaculata** *form. nov.* (18e), from the province of Tucuman in Argentina, the sub-*immaculata*. marginal markings are completely absent above and beneath; the under surface of the forewing is white with small yellow stripes in the apex, the veins are narrowly black, the black line on the discocellular is not widened; the hindwing is yellowish white, with bright yellow, sharply defined narrow stripes between all the veins and at the costal margin, the veins themselves are very finely light, being narrowly edged with grey-black, a similar stripe, indistinctly forked at the discal end, is placed in the cell, the discocellular is light like the ground-colour. ♀ yellowish, veins rather broadly dark, with submarginal arrow-spots on the forewing and more distinct ones on the hindwing.

T. orthodice *Weym.* (18e), from the high mountains of Bolivia, has a white upper surface with the *orthodice*. markings as shown in the figure. Under surface of the forewing white with yellowish apex, in which the white veins are dark-edged. Under surface of the hindwing sulphur-yellow, the veins broadly white, dark-edged, saffron-yellow stripes at the costal and hindmargins, as well as in the cell, which has likewise a blackish stripe. ♀ unknown.

4. Genus: **Pieris** *Schrk.*

This genus, distributed over the whole world, is considered as the typical representative of the family. The subcostal of the forewing is four-branched with 2 branches before the apex of the cell, the third branch is very short and runs into the costal margin shortly before the apex, the cell is large, not over broad, and is closed by 2 discocellulars; the upper discocellular is wanting because the upper radial is coincident with the subcostal for some distance. The precostal of the hindwing branches off from the costal almost at right angles and its pointed apex is curved distad. The costal margin of the forewing is smooth, the antennae have in general a distinct club and are mostly of medium length, very long in some species, the palpi mostly project beyond the head and are densely covered with stiff hairs in front, the end segment is as long as or longer than the middle segment, slender and pointed, the middle segment is but little shorter than the weakly curved basal segment. The larva is cylindrical, with very short hairs, and has light longitudinal stripes. Pupa moderately slender, with obtuse tip to the head and several small protuberances on the dorsum, sometimes with the wing-cases somewhat more produced. The species which belong here have probably all of them at least two broods, one of which in the temperate zones hibernates in the pupa.

P. monuste *L.* (= *hippomonuste* *Hbn.*, *feronia* *Stph.*, *phileta* *F.*, *albusta* *Sepp*) occurs in several *monuste*. forms from the south of North America (the Gulf states) to Argentina, also in the mountains of the west. The form from Surinam may be regarded as the nymotype of the species. — **orseis** *Godt.* (18e, f), from *orseis*. the southern states of Brazil, has the margin more broadly black with white apical spots, the ♀ mostly with yellowish ground-colour, especially on the hindwing, on the latter also rather large pointed black marginal spots. **cleomes** *Bdr.*, from the south of North America, is somewhat smaller and less blackly marked. — *cleomes*. **virginia** *Godt.* (= ♀ *eubotea* *Godt.*?) is the form from the Antilles. — Of **evonina** *Bdr.*, from Cuba, 3 forms *virginia*. are described: **evonina** with greenish white colouring of the ♂, marginal marking narrow, reddish, brown; *evonina*. underside at the apex of the forewing pale and dirty ochre-yellow, hindwing of the same colour, without spots; **valei** *Bdr.*, upper surface white, marginal pattern narrow, black and dentate: under surface of the *valei*. forewing brownish, of the hindwing whitish, faintly ochre-yellow; **joppe** *Bdr.*, smaller than *monuste*, above *joppe*. dull white, marginal pattern dark brown, a black spot at the apex of the cell. — **automate** *Burm.*, from *automate*. Argentina, has only small blackish markings at the apex and the distal margin of the forewing. — **suasa** *suasa*.

Bdr., from Chile, Peru and Bolivia, has somewhat more black markings than *autodice*. Larva violet, with citron-yellow longitudinal bands, head, legs and underside greenish yellow. Pupa pale yellowish, with blackish dots, a small hump on the middle of the dorsum. Lives on *Cleome pentaphylla* and other allied plants and causes the same damage to agriculture and horticulture as *brassicae* and *rapae* in the Palaearctic Region.

sevata. **P. sevata** *Fldr.* (18f), from Colombia, Venezuela and Central America, is similar to *monuste*, but is distinguished from it by a broad layer of scent-scales along almost all the longitudinal veins of the forewing and also two veins of the hindwing. The under surface of the ♂ is yellowish white, the apex of the forewing somewhat darker yellow, the costal margin of the hindwing narrowly edged with ochre-yellow. — In

tiburtia. **tiburtia** *Fruhst.*, from Guatemala, the black apical spot has almost entirely disappeared and the black median spot is reduced, apex of the forewing beneath yellowish white, hindwing beneath with more vivid gloss,

timotina. rose-coloured instead of yellowish, veins not suffused with black. — **timotina** *Fruhst.*, from Peru, is larger, with broader and more extended black margin, which is deeply dentate, a large black median spot, under

amphissa. surface darker, median spot sharper and the veins more distinctly streaked with brown. — **amphissa** *Fruhst.*, from Bolivia, is smaller than *tiburtia*, upperside yellowish white, entirely without markings, only the costal margin of the forewing lightly suffused with brown, without median spot, underside of the forewing white with yellowish apex and brown median spot, hindwing uniform pale yellowish white with orange-coloured basal spot.

sincera. **P. sincera** *Weym.* (18f), from Ecuador (Guayaquil), is greenish white above with black apical and distal-marginal area on the forewing as well as very small black marginal markings on the hindwing. The underside is lighter and without markings except a yellow stripe at the costal margin of the hindwing.

buniae. **P. buniae** *Hbn.* (= *endeis* *Godt.*) (19a) is the giant of the American species of *Pieris*. From this form, which occurs in the central provinces of Brazil, **ausia** *Bdr.*, from the southern provinces, is distinguished by a somewhat more extensive development of the black markings, which in both sexes sometimes occur

rusella. also in the middle and at the distal margin of the hindwing beneath; to ab. **rusella** *Fruhst.*, belong ♀♀ in

digentia. which the black band of the forewing is wanting (Bahia, Espiritu Santo). ♀-ab. **digentia** *Fruhst.*, from Bahia,

sabella. is remarkable for the specially broad black band of the forewing. — **sabella** *Fruhst.* (= *ausia* *Stgr.*), from

pharetia. the Upper Amazon, has no markings at all on the under surface of the hindwing. — **pharetia** *Fruhst.*, from Peru, is larger, the apical spot of the forewing beneath is effaced, the underside of the hindwing only with

imperator. traces of a brown transverse band or without even these. — **imperator** *Kirby*, from the Upper Amazon, is the most darkly marked form; in it the ♀ has also on the upperside of the hindwing abundant black markings and on the upperside of the forewing a curved black band occupying half the costal margin and the dis-

phaloë. cocellular. — **phaloë** *Godt.*, from the Upper Amazon, is smaller and with less markings than *imperator*. —

diana. **diana** *Fldr.*, from Colombia, has the black apical and marginal markings diffuse. — **sublineata** *Schaus* (19a),

sublineata. from Peru, is distinguished chiefly by the strongly yellow colouring of the hindwing beneath. — All the forms of *buniae* have an even broader layer of scent-scales at the veins than *sevata*.

amaryllis. **P. amaryllis** *F.* (19a), from Jamaica, differs from *josepha* by the 'café-au-lait' colouring. — **josepha**

josepha. *Godm. and Sqr.* (19a), from Mexico and Central America, also discovered by Herr L. HARTMANN of Würzburg in Texas, is undoubtedly nearly allied to the preceding species, but must certainly be regarded as a separate species on account of the peculiar form of the ♂ and the style of marking of the ♀. On the under

gervasia. surface besides the black median spot of the forewing there are only quite small dark markings present in the middle of the wings. ab. **gervasia** *Fruhst.* is a female form which has a white under surface with grey-

josephina. yellow scales. — **josephina** *Godt.* is the form from San Domingo. — **protasia** *Fruhst.*, from Honduras and

protasia. Nicaragua, has a much smaller black median spot. — **krugii** *Dew.*, from Porto Rico, is smaller, the distal

krugii. margin of the forewing more incurved, the black spots almost completely effaced.

menacte. **P. menacte** *Bdr.* (19b), from southern Brazil and Paraguay, is white above with dark scaling (sometimes wanting) at the apex of the forewing. The ♀ has much darker markings. The under surface is yellowish white with more or less blackish scaling (sometimes absent) along the veins of the hindwing.

cruciferarum. **P. cruciferarum** *Bdr.* (= *casta* *Ky.*, *marginalis* *Scudd.*) (18f), from California, is plain yellowish white above, beneath more strongly yellow, with ochre-yellow stripe and narrow black edging to the veins of the hindwing.

rapae. **P. rapae** *L.* (19b) was introduced into Canada about 1860 and has since spread as far as Hudson's

novangliae. Bay and South Texas. The larvae cause great damage every year. ab. **novangliae** *Scudd.* is a sulphur-yellow form. — Larva light green, velvety, with a fine yellow longitudinal line on the back, paler laterally with a narrow yellow stripe in which the black spiracles are placed, venter yellow-green, head brownish yellow, 20–30 mm. long. Lives on cabbages, Reseda, cress, etc. Egg pear-shaped with longitudinal ridges and transverse folds, laid singly. Pupa yellow, greenish grey or brownish with 3 yellow stripes.

P. napi L., although distributed over the whole of North America, is much rarer there than in the *napi*. Palaearctic Region. The summer form *napi* differs from the spring form **oleracea** Harris by more abundant *oleracea*. dark markings, especially on the under surface, whilst in the Palaearctic Region on the contrary the spring form has more markings; ab. **virginiensis** Edr. (19b) is distinguished from *oleracea* in that the forewing has *virginiensis*. an indistinct dark apical spot on the upper surface and on the under surface of the hindwing there is very fine but broad dark scaling along the veins, but specimens also occur in which the whole of the hindwing beneath is darkened except for the fine white veins: such specimens have also broad grey streaks at the veins at the apex of the forewing beneath; ab. **pallida** Scudd. is purer white above and beneath, only the *pallida*. ♀ has a small black spot on the upperside of the forewing. — The alpine and northern form **bryoniae** Ochs., *bryoniae*. which occurs in Alaska as well as in some parts of the Palaearctic Region, has in the ♀ yellowish ground-colour on the upper surface and rather broad dark margins to the veins. This form is considerably lighter than the Palaearctic form of the same name. — **acadia** Edr. is a large form, which comes between *pallida* *acadia*. and *bryoniae* in colouring and pattern. — **frigida** Scudd., from Labrador, is a whiter form and **hulda** Edr. *frigida*. (19b), from Alaska, is similar to *frigida*, but much smaller. — **castoria** Reak. (= *resedae* Bdr.), from Cali- *hulda*. fornia, is a form without much marking. — Larva brownish green, lighter at the sides, with small white *castoria*. tubercles, black dots and a yellow lateral stripe, above which the black, red-yellow edged spiracles are placed, head grey-green; 29–30 mm. long, on the same plants as *vapae*. Pupa greenish yellow, with black spots and dots and yellowish margin to the wing-cases. Egg pear-shaped, likewise laid singly.

P. protodice Bdr. (19c), distributed from Canada to Guatemala, has white ground-colour, a large *protodice*. median spot divided with white and in the ♂ slighter, in the ♀ stronger pattern of marginal and submarginal spots on the forewing. The upper surface of the hindwing in the ♂ is almost without markings, in the ♀ with submarginal dentate markings as well as black marginal spots. The under surface has much paler markings in both sexes. — In the winter form, **vernalis** Edr., the ♂ is smaller and less marked than the ♂ of *proto-* *vernalis*. *dice*, the ♀ on the contrary scarcely different from that of *protodice*. — Larva in the earlier stages unicolorous orange-yellow, head black, in the later stages the head light straw-colour, posterior half light purple, a gold-yellow spot on each side, the whole head sprinkled with black-brown, eyes purple, broadly edged with black. Body alternately glossy gold-yellow and dark greenish purple, sometimes with uniform, in other cases with unequally broad black band. The yellow colouring of the sides of the back and of the stigmatal band runs into the purple of the infrastigmatal band. Beneath dull light green with reddish tinge. On the whole body larger and smaller black spots, each of which bears a short black hair, also numerous small hairy tubercles (from specimens preserved in glycerine). Pupa light bluish green, slightly suffused with yellowish on the abdominal segments, a dull, broad yellowish lateral stripe on the abdomen, suprastigmatal ridges margined with yellow. Head with small, dispersed blackish spots, wing-cases with faint dark brown marks, veins marked with small, separated, distinct black spots, a black spot on the basal protuberance, segments of the antennae mostly marked in the same way. The spiracles are the same colour as the body. Larva on *Brassica oleracea*, *Lepidium virginicum* and other Crucifers.

P. occidentalis Reak. (19c), from the mountainous regions of the west of the United States, has the *occidentalis*. dark markings more extended and less interrupted than *protodice* and the under surface, especially of the hindwing, is strongly marked with green. — *occidentalis* is regarded by SCUDDER as the third generation of *protodice* (only occurring in the west?). Thus it would seem that the early stages do not differ from those of *protodice*.

P. sisymbrii Bdr. (19c), from the United States, is smaller than *occidentalis*, the black marginal mark- *sisymbrii*. ings are more sharply defined and divided by the veins, which are light here, but sharply dark in the rest of the wings. The underside of the hindwing has black-green markings, broken up in a peculiar manner. The ♀ is quite similar to the ♂. — Egg long, narrow, conical, ground-surface and vertex flattened and depressed, with longitudinal ridges, the interspaces hollowed out and crossed by numerous stripes; colouring at first light yellow, shortly before emergence red. Full-grown larva about 22 mm. long, cylindrical, moderately narrowed anteriorly and posteriorly, light yellow, with black stripes crosswise, each segment sometimes with a fold and in this case on the back small yellow protuberances of irregular size, each terminating in a small fine hair: on all the segments behind the 2. and inclusive of the 12. are 2 stripes. The larva varies very much. Time of development from the egg to the pupa in April – May 33 days, in May – June 30 days. Pupa cylindrical, narrow at the head, hollowed out at the sides, a short thick projection between the eyes, mesothorax projecting, rounded, slightly keeled in consequence of a depression as deep as the mesothorax is high, which however is not uniformly rounded but rather angular, on each side of the dorsum and the anterior abdominal segments are small, angular, inconspicuous elevations, the anterior ones the most distinct; colouring dark brown, the whole upperside except the wing-cases irregularly covered with small protuberances (the pupa is figured by EDWARDS, Butterflies of North America, hanging free).

P. beckeri Edr. (19c), from the United States, is similar to the *Euchloa*-species. Upper and under *beckeri*. surface white, on the upperside of the forewing a large black median spot, divided with white, and smaller

and indistinct marginal and submarginal spots. Under surface with a large black median spot and two black submarginal spots, as well as greenish markings at the apex of the forewing and at the distal margin, in the middle and at the base of the hindwing, veins for the most part yellow. — Full-grown larva about 33 mm., colouring greenish white, strongly mottled or sprinkled with grey, and with a very distinct orange-coloured belt between the segments, each segment with 16–18 pitch-black tubercles, terminating in black bristles, head yellow. Pupa in general like that of *protodice*, but less angular; the frons ends in an obtuse projection, the head part is rounded, with uneven upper surface, the dorsal side of the thorax is dark grey-brown, the elevation above the wing-cases, which *protodice* possesses, is wanting in *beckeri*, the rest is grey, on the wing-cases and the back of the first two abdominal segments almost white; a light stigmatal stripe runs from the margin of the wings to the anal extremity, between thorax and abdomen are 4 small spots dorsally. Duration of the pupal stage 15 days. Lives on Crucifers. The first generation flies in April, the second from the end of June for 3–4 weeks. No differences have been found between the butterflies of the two broods.

venosa. **P. venosa** Scudd. (19c), from California, is white on the upper surface with the veins scaled with black in the anterior part of the forewing and black dots at the ends of the veins on the hindwing, as well as a black spot on the forewing between the 2. and 3. median veins, on the yellowish white under surface all the veins are rather broadly and very darkly margined, but the veins themselves light.

itaticayae. **P. itaticayae** Foett. (19d), from Brazil, is white on the upperside with yellow stripes between the veins and black apical area on the forewing and small black marginal marking on the hindwing. The under surface of the forewing is white, yellow at the costal and distal margins, the hindwing is darker yellow and the veins with dark margins.

aripa. **P. aripa** Bdr. (19d), from Venezuela, has yellowish white upper surface, with black apical and distal-marginal marking, the under surface is somewhat lighter with a black median spot on the hindwing, at the apex of the forewing the black marking of the upper surface shows through. — **balidia** Bdr., from *clodia*. Mexico, is generally more yellow, especially on the underside of the hindwing. — **elodia** Bdr., from Mexico, is not essentially different. It would be most correct to unite all the three forms. *P. aripa* occurs from Mexico to South Brazil, is nowhere rare and varies somewhat. The ♀♀ have more yellowish ground-colour; probably *clodina*. *balidia*, which I only know from the figure, is an *aripa*-♀. — **elodina** Stgr. i. l., from Bolivia, is larger and on the under surface almost pure white.

eleusis. **P. eleusis** Luc. (19d), from Colombia and Venezuela, differs from *clodia* by its much more pointed forewing, broader apical and distal-marginal marking, and also by the black marking in the cell of the forewing above. The ♀ has a yellowish upper surface to the hindwing and broader black marking in the cell of the hindwing. — **helena** Luc., from Ecuador, has a narrower black margin, less black dusting at the costal margin and lighter, almost white, under surface.

pylotis. **P. pylotis** Godt. (19d), from Brazil, is white above with broad black apical and distal-marginal marking, and also a black median spot on the forewing, the hindwing has black spots at the distal margin, but is, however, not infrequently entirely white. The under surface is similar to the upper, but the distal margin of the forewing is light grey, the hindwing has a black spot at the discocellular and an ochre-yellow one at the base. The ♀ only differs by a yellowish tone on the hindwing beneath.

olympia. **P. olympia** Fldr. (19e), from Venezuela, Colombia and Peru, has white ground-colour with black distal-marginal area and a small black median spot on the forewing, the under surface is silver-white with black submarginal markings on the forewing and fine black veins on the hindwing.

tovaria. **P. tovaria** Fldr. (19e), from Colombia and Venezuela, differs from *olympia* in the more normal distal-marginal area and the absence of the black median spot of the forewing. The ♀ has broader, but paler submarginal markings and the hindwing is yellowish beneath. — **subflavescens** Kirby, from Ecuador, has the hindwing yellowish beneath and the apex of the forewing sulphur-yellow. — **maruga** Fruhst., from Ecuador, is larger than *tovaria*, with much broader black margins, the underside of the forewing darker in the cell *gina*. and the stripes between the veins are sharper. — **gina** Fruhst., from Peru, is larger than *maruga*, forewing more pointed, the black distal margin essentially broader, more deeply indented proximally, the base of the wing with less black scales, beneath the black band on the forewing broader.

philoma. **P. philoma** Hew. (19e), from the high mountain ranges of Ecuador and Peru, is white above with very broad black margins and a white subapical spot on the forewing. The under surface of the hindwing and the apex of the forewing are silver-white with sharp, thin black veins and stripes between the veins, the forewing has also the corresponding submarginal marking on the upper surface.

euthemia. **P. euthemia** Fldr. (19e), from Colombia and Venezuela, is distinguished from *philoma* by much narrower black markings; the hindwing is white except for a narrow black margin.

penthica. **P. penthica** Koll. (19e), from Colombia, is also similar to *philoma*, somewhat larger, with less black markings, the hindwing is blue in the posterior half, the under surface of the hindwing, in addition to the

very fine, much less conspicuous black veins, has only traces of the black stripes between the veins at the distal margin, on the other hand a rather large black spot on the discocellular. — **stamnata** *Luc.*, from Venezuela, *stamnata*. is somewhat smaller, but otherwise differs little from *penhica*. — **messala** *Fruhst.*, from Peru, has the forewing more pointed, beneath the cell of the forewing is more broadly scaled with black and the subapical black transverse band is somewhat narrower. — **basiliola** *Fruhst.*, from Bolivia, is smaller and lighter, the white subapical spot of the forewing broader, the black distal margin of the hindwing decidedly narrower and the anal area of the hindwing above almost without blue-grey scaling.

P. subargentea *Btlr.* (19e), from Peru, has the upper surface almost black, with white-yellowish markings. The under surface of the forewing is similar to the upper, only the apex is bluish instead of black. The underside of the hindwing is bluish with silvery sheen, the middle of the wing whitish, at the costal margin a yellow stripe and the veins and the stripes between them are narrowly black. — **lia** *Fruhst.*, from Bolivia, is larger and is less extended black.

P. caesia *Luc.*, from Ecuador, is distinguished from **tenuicornis** *Btlr. and Druce* (194), from Central America, by narrower black distal margins and the almost complete absence of the sulphur-yellow scaling at the apex of the forewing beneath. The ♀ is black-brown except for the white median and apical markings of the forewing and the yellowish middle of the hindwing, and has also a broad grey-brown submarginal band on the underside of the hindwing. — **semicaesia** *Fldr.*, from Colombia, is a small form with narrower, pale black-brown margins and impure blue on the under surface. — **phanokia** *Fruhst.* (= *semicaesia* *Fldr.*?), from Colombia, of which only ♀♀ are known, is larger than *caesia* and has on both wings a much broader margin above and beneath.

P. cinerea *Hew.* (19f), from Ecuador, has the upperside of the forewing white with the apical half black, in which a white apical spot is placed, the hindwing in the ♂ is blue and in the ♀ black with yellow-white costal margin. The under surface is quite similar except that there are small sulphur-yellow spots at the apex of both wings, a stripe of the same colour at the costal margin and small ochre-yellow spots at the base of the hindwing. The ♀ is paler coloured, the spots at the apices of the wings and stripe at the costal margin of the hindwing on the underside are white instead of yellow. — **litana** *Fruhst.*, from Bolivia, is smaller, the black distal margin narrower, the under surface of the forewing purer white, that of the hindwing paler yellow. — **menthe** *Hopff.* is the slightly different form from Peru.

P. mandela *Fldr.* (20a) is the oldest name for a species particularly rich in female forms. *P. mandela* is the form from Venezuela with moderately broad black apical marking, in which are one larger and several very small white subapical spots, and with very narrow black distal margin to the hindwing. The under surface of the hindwing is lighter than in the better known *locusta* from Colombia. ♀ more like the ♂ than the ♀♀ of the other forms, distinguished from the ♂ by the broader black margin and the yellowish tint of the rest of the hindwing. — **apicalis** *Btlr.*, from the Upper Amazon, Peru, Colombia and Ecuador, is larger in both sexes, in the ♂ the black apical margin more sharply angled proximally, the distal margin distinctly narrower posteriorly, the upper white subapical spot larger, the distal margin of the hindwing broader in the posterior half, the under surface lighter; the ♀ is similar to the *mandela* ♀, the proximal part of the hindwing grey-brown to the end of the cell, the under surface of the forewing not sulphur-yellow at the base, the hindwing has more red colouring, the brown parts are more coffee-brown and the submarginal spots larger. — **noctipennis** *Btlr. and Druce* (20a), from Costa Rica and Chiriqui, has in the ♂ a somewhat broader black distal margin to both wings than *mandela*. The under surface of the hindwing is somewhat darker and the yellow marginal spots are sharper and deeper yellow. The ♀ has the upper surface of the forewing more yellowish with black apical third in which a yellowish subapical spot is placed, the base is yellowish grey-brown, the hindwing is black-brown with two small yellow subapical spots. — **locusta** *Fldr.*, from Colombia, is scarcely different from *noctipennis* in the ♂, the ♀ on the other hand has the distal third of the forewing and the whole of the hindwing a deep purple-brown colour; a small white subapical spot on the forewing is sometimes present. The white colour of the middle part of the forewing is tinged with red. The under surface of the hindwing is darker and the yellow submarginal spots are more indistinct. — **rubecula** *Fruhst.* (20b), from Peru, has in the ♂ three distinct subapical white spots, the black apical and distal-marginal marking only reaches to the first median vein, the hindwing is more broadly margined with black and the under surface of the hindwing is very light, with much yellow marking and vermilion streaks at the base. The ♀ has a black central longitudinal band from the cell to the distal margin of the forewing. — **xanthomelas** *subsp. nov.*, from Ecuador (Coca), is in the female similar to *rubecula*, the hindwing has strongly yellowish ground-colour, which is also present on the basal part of the forewing, also the hindwing is much darker, the black central longitudinal band of the forewing is shorter and narrower, the under surface of the hindwing is much darker and the vermilion and yellow streaks are longer and stronger. — **pallida** *subsp. nov.*, from Bolivia (Yungas de la Paz, 1000 m.), has a smaller black apical part to the forewing above, with its proximal edge rather straight, and broad, diffuse black distal margin to the hindwing. The under surface, particularly on the hindwing, is very light and only diffusely marked. — **tithoreides** *Btlr.*, from Ecuador (Balzabamba), has in the ♂ a broad black distal margin to both wings, the hindwing

has a row of small white submarginal spots, under surface dark, yellow markings darkened, the red basal markings and yellow spots reduced. ♀ with yellow longitudinal central band on fore- and hindwing, a white transverse median band and white submarginal spots on both wings. — **cocana** *Fruhst.*, from Ecuador, is only distinguished from *rubecula* on the upperside by the narrower black distal margin of the hindwing. The under surface of the hindwing has white instead of reddish ground-colour, sharp dark marking and the yellow and red markings very much reduced. ♀ unknown. — **permagna** *Fruhst.*, from Peru (Chanchamayo), is similar to *cocana*, the red basal spots on the underside of the hindwing are enlarged and the submarginal spots larger and whitish yellow. — **molione** *Fruhst.*, from Paraguay, is the most southern subspecies and has the least markings of any; it is smaller than *rubecula* and has a much narrower, lighter grey-black distal margin to the hindwing, which is proximally broken up into fine blue-grey scaling; the light grey under surface of the hindwing recalls *viardi* in the fine yellow stripes between the nervures.

P. viardi *Bdr.* (= *habra* *Doubl.*) (20b), from Honduras, is white above in the ♂, with black, white-spotted apical and distal-marginal markings and a large black median spot on the forewing, which however is sometimes wanting, and entirely white hindwing. Underside of the hindwing similar to *mandela*, but much lighter and the light yellow submarginal spots diverging from the margin from the middle of the distal margin towards the inner margin, markings of the forewing beneath as above, only much paler. ♀ above and on the under surface of the forewing black-brown with vivid yellow bands and spots, under surface of the hindwing as in the ♂, only darker. — **laogore** *Godm.*, from Mexico and Guatemala, has lighter markings on the underside of the hindwing and has no sulphur-yellow markings there.

5. Genus: **Leptophobia** *Bthr.*

This genus cannot be maintained in the wide limits laid down by the author, but may be defined according to the characters observed in the genotype *eleone* *D.-H.*, with which only a few of the 15 species included by Butler are congeneric. The principal characters of this genus consist in the formation of the precostal, which is curved proximally, and in the shortness of the middle discocellular, which is scarcely $\frac{1}{4}$ as long as the weakly curved and less obliquely placed lower discocellular. The subcostal is four-branched with two branches before the apex of the cell, the upper radial is stalked with the subcostal almost to the half. The long antenna (reaching to $\frac{2}{3}$ of the margin of the forewing) is not characteristic for the *Leptophobia*-species, but occurs also in some species of *Pieris*.

L. eleone *D.-H.* (= *suadella* *Fldr.*) (20c), from Colombia and Venezuela, has the forewing pointed and the hindwing produced at the anal angle. The ♂ is lemon-coloured above with broad black distal margin and narrowly black hindmargin on the forewing, somewhat more than the anterior half of the cell being also black. The ♀ is light yellow on the hindwing, almost white on the forewing, but marked like the ♂, though ♀♀ also occur with light ochre-yellow forewing and lemon-yellow hindwing: ab. **ochracea** *form. nov.* The under surface of the hindwing and the apex of the forewing are yellowish white, with a pearly gloss, the rest of the forewing light yellow, the hindwing has two small black spots on the discocellular and small black marginal spots. — In **doubledayi** *Stgr. i. l.*, from Bolivia, the tooth in the black distal margin is shorter and the under surface of the forewing deeper yellow. — **luca** *Fruhst.*, from Bolivia and Ecuador, has a narrower black distal margin and no black border at the inner margin. — **conica** *Fruhst.*, from Colombia, is an aberration of *eleone*, in which the tooth in the black distal margin is prolonged. — **euremoides** is the name given by FRCHSTORFER to that form which is only margined with black towards the apex and in which the cell is lightly scaled with black only at the costal margin. — The butterflies fly over fields and in thickets and are fond of being driven by the wind.

L. smithi *Kirby* (20c), from Bolivia and Peru (3000 m.), has the wing-shape as in *eleone*, is lemon-yellow above in the ♂, light orange-yellow in the ♀, the distal-marginal markings are much narrower and the cell is not coloured with black. The under surface is more greenish than in *eleone* and the black marginal spots are wanting.

L. eucosma *Ersch.* (20c), from Peru, is larger than *smithi*, has the same yellow upper surface with black apical marking on the forewing, the underside is much lighter and has small black dots on the veins at the distal margin of the hindwing. — This species is only known to me from the figure, consequently I cannot state positively whether it belongs in this genus.

L. pinara *Fldr.* (20c), from Colombia (and Peru?) (3000 m.), has the peculiar form apparent in the figure. Upper surface white with black apical and distal-marginal markings, black median spot on the forewing and slight traces of black colouring at the anal angle of the hindwing. Under surface white, on the discocellular of each wing a black spot, as well as small black marginal spots on the hindwing, the latter and the apex of the forewing glossy. — **oiantheia** *Fruhst.*, from Peru, is smaller and has a narrower black distal margin on both wings, smaller median spot on the forewing and pure white apex to the forewing beneath.

L. nephthis *Hopff.* (20 c), from the mountains of Peru (3000 m.) and Bolivia, does not differ materially in shape from the *Pieris*-species. The upper surface is white, the forewing has rather broad black marking at the apex and the distal margin, the anterior half of the cell being also black, and the hindwing has a narrow black margin. The under surface is white, on the hindwing somewhat glossy, the forewing has the marking as above, but somewhat reduced, the apex is light, the hindwing has a small black median spot as well as a few very small black marginal spots at the posterior part of the distal margin. — **aymara** *aymara*. *Fruhst.* is an aberration with quite narrow black distal margin on the hindwing and interrupted subapical band on the forewing.

L. erinna *Hopff.* (20 d), from Peru, is likewise only known to me from the figure, hence I am not certain of its generic position. The upper surface is slightly yellowish white with rather broad black markings at the apex and the distal margin and large black median spots on the forewing, the hindwing with only very small black marginal markings. Underside similar, only with bluish instead of black apical and marginal markings on the forewing; hindwing with small black dots at the distal margin. The ♀ is yellower above and beneath and has paler and somewhat more copious black markings at the distal margin of the forewing.

L. cinnia *Fruhst.* (20 d), from Ecuador, has white upper surface with rather broad black markings at the apex and the distal margin, a black median spot and black costal margin on the forewing and also an interrupted black marginal line on the hindwing. The under surface is white with a black median spot on the forewing and strongly silvery gloss on the whole of the hindwing and at the apex of the forewing. ♀ unknown. — **falledra** *Fruhst.*, from Colombia, has a broader black costal margin on the forewing, especially in the distal part of the cell, and a broader black distal margin.

6. Genus: **Itaballia** *Kaye.*

The character of this genus consists in the formation of the precostal, which is not placed at right angles to the costal as in *Pieris*, but is strongly curved and in its distal part runs almost parallel to the costal; otherwise it has no structural differences from *Pieris*. From *Perrhybris*, with which it was united until recently, it is distinguished by the four-branched subcostal.

L. demophile *L.* (= *molphea* *Cr.*) (20 e), occurring from Colombia to Paraguay, is white above in the ♂, with black apex and black subapical half band, hindwing very narrowly margined with black, under surface of the forewing white, marked as above, but the subapical band reaching to the costal margin, hindwing yellowish with very broad black-brown margin. ♀ above and beneath yellowish, the subapical band broader and reaching the costal margin above also, costal and distal margins of the hindwing broadly grey-black. — **calydonia** *Bdr.*, from Central America and Venezuela, is somewhat smaller, less marked with black and the under surface of the hindwing without any dark markings. — **amathonte** *Cr.* is a very dark (perhaps rainy seasonal) form of the ♀. — **charopus** *Fruhst.*, from Rio Waupes, is distinguished by a narrow black costal margin of the forewing and the lesser development of the subapical spots, distal margin of the hindwing with moderately broad black scaling, veins suffused with black, beneath the subapical band of the forewing and the distal margin of the hindwing narrower. — **niphates** *Fruhst.* has the black spots much narrowed, hindwing with quite narrow antimarginal line, under surface of the forewing also less marked with black, hindwing diffusely margined with brown-black. Para. — **nimietes** *Fruhst.*, from Bahia, is distinguished from *demophile* by narrower and more sharply defined yellowish transverse bands on the forewing, under surface with longer subapical band. — **huebneri** *Fruhst.*, from Rio de Janeiro, is similar to *amathonte*. **niseias** *Fruhst.*, from Paraguay, is similar to *calydonia*: small, distal margin of the upper surface broader, markings otherwise as in *charopus*, under surface similar to *niphates*, but the black distal margin extending to the anal angle, hindwing with a rather broad, complete band of uniform width, which is sharply defined proximally. — **minthe** *Fruhst.*, from Ecuador, is essentially smaller than *charopus*, the wings are more roundish, the upper surface of the forewing with extended black apical spot, the hindwing however more narrowly margined with black and in the anal angle with a narrow, densely scaled area, under surface of the hindwing pure white, the black distal margin narrower; ♀ above with very broad white areas, the base of the cell yellowish with grey scaling, hindwing mostly white, the black distal margin deeply indented. — **lucania** *Fruhst.*, from Peru, is approximately as large as *niseias*, apical spots of the forewing narrower than in *minthe*, black scaling on the hindwing less extended; ♀ with light ochre-yellow ground-colour, black distal margin of the hindwing less indented, very broad at the anal end, beneath the distal margin of both wings brown, the ground-colour suffused with ochre-yellow. — **mustica** *Fruhst.*, from Bolivia, is very similar to *huebneri*, but the white central area of the hindwing more extended beneath; ♀ differing from *lucania* in the pale and diffuse yellowish ground-colour, under surface of the forewing whitish, yellowish towards the margin, cell suffused with yellowish, distal border of the hindwing obsolescent and in the middle part much narrowed.

L. pandosia *Hew.* (20 d), from Venezuela, is white above and beneath, with black margins and above with black base, on the under surface of the hindwing with small red-yellow spots in the dark distal margin.

leptalina. **leptalina** Bates (= *pisonis* Stgr.) is the form from the Upper Amazon. — **sabata** Fruhst., from Colombia, is smaller than *pandusia*, has a diffuse transverse band on the discocellular and more deeply incised black distal margin, the underside is yellowish, the white spots of the forewing are smaller and the black bands sharper. — **ophelia** Fruhst., from Peru (October), shows a stronger development of the black markings, larger white spots on the under surface of the forewing and a more intensively red band on the underside of the hindwing. — **ludovica** Fruhst. is the dry-seasonal form of *ophelia*; it is decidedly smaller and has the subanal band on the hindwing narrower (February).

marana. **I. marana** Doubl. (20d), from Ecuador, is similar to *pandusia*, but has on the upperside broader black margins and on the underside of the forewing a black subapical band as well as a similar median band on the under surface of the hindwing, which in the basal part is divided by a red-yellow band; the ♀, which is yellowish white above, stronger yellow beneath, has on the upper surface of the forewing a black subapical band and broader black margins.

pisonis. **I. pisonis** Hew. (20d), from Colombia and Peru, differs from **kiçaha** Reak., from Honduras, in that *kiçaha.* the black subapical band is complete above and beneath. Both forms have beneath at the margin of the forewing small white spots and at the distal margin of the hindwing a red-yellow macular band.

7. Genus: **Perrhybris** Hbn.

This genus differs from *Pieris* by the three-branched subcostal, there are no other sharp structural differences, but it is well characterised by the Heliconine-like style of marking, strongly developed in the ♂♂ only beneath but in the ♀♀ on both sides, which makes it probable that it belongs to another evolutionary stirps than the *Pieris*-species. Following the example of KAYE, we have removed the species with four-branched subcostal, which are also well differentiated from *Perrhybris* in facies, especially by their slighter sexual dimorphism, and placed them with the preceding genus *Itaballia*.

lypera. **P. lypera** Koll. (20e), from Colombia (and Central America?), is in the ♂ white above with black apical part of the forewing and broad black distal margin on the hindwing, under surface of the forewing like the upper, hindwing yellow with broad black margin, a similar longitudinal band in the anterior part, in which is placed a short red band starting from the inner margin, and a black stripe at the costal margin. ♀ black above and beneath, similarly marked on both sides, on the under surface of the hindwing as in *paravicinii.* the ♂ a red half band. — **paravicinii** Fruhst., from Ecuador (Balzabamba), has longer and narrower wings, a decidedly narrower black distal margin, on the underside of the forewing the cell is lighter, the apical spot somewhat smaller, on the underside of the hindwing the margin narrower in the posterior half, the subbasal band white and pointed, central area light yellow proximally, distally white instead of dark yellow.

pyrrha. **P. pyrrha** F. (= *iphigenia* S hufz) is distributed from Central America to South Brazil (São Paulo) and from the east coast to the Upper Amazon. The upper surface of the ♂♂ presents the facies of a typical White, whilst the ♀♀ are similar to the Heliconines. The so-called type-form *pyrrha* occurs in Surinam, from *digitata.* which **digitata** Fruhst., from Espiritu Santo, is distinguished in the ♂ by a narrower black distal margin and in the ♀ by an uninterrupted yellow band on the forewing. — The ♂♂ of **pandora** form. nov. (20e, f), from Rio de Janeiro and São Paulo, have a completely black hindwing except for a black marginal line, and reduced black markings on the forewing, the ♀♀ a much broken, light yellow (commonly sulphur-yellow) band on the forewing. — **ecieidias** Hbn. is probably a seasonal form from Surinam, with entirely white hind- *lucasi.* wing in the ♂ and very narrow black median band on the hindwing in the ♀. — **lucasi** Fruhst., from Cayenne, is a ♀-form with very broad yellow band on the forewing, the red median band on the hindwing being almost without dentition. — **pamela** Cr. is a ♀-form with strongly developed black markings on the *amazonica.* hindwing. — **amazonica** Fruhst. (= *pyrrha* Stgr.), from the Upper Amazon, has in the ♂ a narrow black margin on the hindwing and in the ♀ a moderately dentate band, red above and yellow beneath, on the *incisa.* hindwing. — **incisa** Fruhst., from Bahia, has in the ♂ a broader margin on the hindwing than *amazonica*, in the ♀ the much broken yellow band of the forewing is broadly margined with black near the base and *malenka.* the red band of the hindwing is produced into fine points. — **malenka** Hew., from Venezuela and Colombia, has in the ♂ the upper surface of the hindwing entirely white and the under surface with only a few pale markings, the ♀ has narrower wings, two red-brown bands reaching almost to the margin and only small *ostrolenka.* subapical spots, whilst **ostrolenka** Stgr., from Chiriqui and Panama, is almost without markings beneath in *bogotana.* the ♂ and the ♀♀ are much darker beneath than *malenka*-♀♀. — **bogotana** Bthr. (= *Mylothris bogotana* Bthr.), from Santo Fé de Bogotá, is in the ♀ similar to *malenka*; the yellow-brown median spots of the forewing and the somewhat shorter submedian longitudinal stripes are sulphur-yellow at the margins; above and well separated from them are two yellow, obliquely placed spots and above the cell three oblong spots of the *glessaria.* same colour in the oblique subapical row instead of the quadripartite band in *malenka*. — **glessaria** Fruhst., from Ecuador (Napo and Coca), has in the ♂ above the marginal band deep black, but moderately broad,

on the under surface of the hindwing with very broad and deep black markings, the ♀ is a beautiful red-brown on the proximal two-thirds of the forewing above, with small but deep black markings, the yellow band occupying all the distal part of the area between the first two median veins very broad and brightly coloured, the hindwing is dark red-brown with broad and prominent black markings. The underside of the forewing is marked like the upper, only with somewhat paler colour, the underside of the hindwing is almost entirely black-brown and has only three narrow brick-red longitudinal stripes and at the anterior part of the distal margin three large lighter spots (not flame-shaped). — **flammula** *subsp. nov.*, from Peru (Chanchamayo), *flammula*. is a large form, in the ♂ almost without any black at the distal margin of the hindwing, also beneath much less marked than *glessaria*, but with a considerable amount of sulphur-yellow at the distal and inner margins of the hindwing and some markings of the same tint also at the distal margin of the forewing. The ♀ has on the upperside but little red-brown colouring, strongly mixed with yellow, the four flame-shaped spots placed at the distal margin of the hindwing are lighter (yellow) than the proximal part and the black markings are much reduced, there is a conspicuous yellow spot at the base before the subcostal, the yellow band on the forewing is narrow and strongly dentate and the black markings are moderately developed. The under surface of the hindwing has a distinctive grey-yellow colour, the black markings at the distal margin are very pale in contrast to the rest of the black markings. — **fruhstorferi** *form nov.*, from Panama, *fruhstorferi*. is a ♀-form with almost entirely black forewing. — **carmenta** *Fruhst.*, from Peru, is probably the dry-seasonal *carmenta*. form of *flammula*; it is considerably smaller and has fewer markings. — **austriana** *Fruhst.*, from Bolivia, is *austriana*. marked like *glessaria* on the forewing, the hindwing has a very narrow black distal margin. ♀ above with lighter and more vivid yellow bands and spots than *carmenta*, distal margin of the hindwing somewhat broader, under surface of the forewing with more yellow spots, the under surface of the hindwing yellower and the red median band more distinct. — The ♂♂ of this species, like most Pierids, are fond of moist places on the ground, the ♀♀ of the forest.

P. flava *Oberth.* (20f), from the provinces of Leopoldina, Espiritu Santo and Bahia, must be regarded *flava*. as a separate species. The ♂ is yellow above and beneath with black apex to the forewing, in which the tooth-shaped projection between the 2. and 3. median veins, which all the forms of *pyrrha* possess, is wanting, the ♀ has on the forewing a band which is sharply defined at both sides and on the hindwing a median band which is likewise yellow but of a deeper tint.

P. lorena *Hew.* (20f), from Ecuador and Colombia, is white in the male above and beneath with *lorena*. black bands, the under surface of the hindwing, in addition to the black markings of the upper surface which may be seen in the figure, has also a black median band extending from the base to the middle of the wing, which is divided longitudinally by a red stripe, and a black stripe at the costal margin. The very differently coloured and marked ♀ has the markings beneath much as above. — **jumena** *Fruhst.*, from Ecuador, *jumena*. is distinguished by a much narrower white subapical band which has the black bordering much broader; on the under surface the red band is reduced and its black border broader. — **luteifera** *Fruhst.*, from Peru *luteifera*. (Chanchamayo), shows in the ♂ the white subapical band running to a point posteriorly, so that a wedge-shaped instead of rectangular spot is formed, underside yellowish instead of white, underside of the hindwing in the marginal and basal areas more extended yellowish. — **peruncta** *Fruhst.*, from Bolivia (Yungas *peruncta*. de la Paz), has broader black bands and the white subapical transverse spot is more symmetrical and narrower, the under surface of the hindwing is more broadly margined with black than in *luteifera* and the subapical band much lighter red.

8. Genus: **Pereute** *H.-Schäff.*

The species of this genus differ widely from the typical Pierids in facies; in the style of marking they have a distant resemblance to some Heliconines, but the form of the wings is quite different; among the Pierids they stand with *Archonias* completely isolated. In neurulation they agree with *Leodonta*: the subcostal is three-branched with one branch before the discocellular, the 2. and 3. branches form a moderately long fork, the precostal is weakly curved basad. The genus has its home about between 20° N. lat. and 30° S. lat.

P. autodyca *Bdv.* (21a), from the Brazilian province of Rio de Janeiro, is in the ♂ black above, *autodyca*. scaled with grey at the apex and on the posterior part of the forewing as well as on the hindwing with the exception of the distal margin, in the middle of the forewing the red band of the under surface shows through indistinctly. The ♀ is only scaled with grey on the basal part of both wings and bears on the middle of the forewing a broad brick-red transverse band, which is divided by the black veins. The dark under surface shows at the costal margin of the hindwing a large tear-shaped sulphur-yellow spot and at the base two red spots; in the ♂ the red band of the forewing is narrowed in the anterior part, the ♂ has further a white-red longitudinal band on the middle of the posterior part of the forewing. — **bardela** *Fruhst.*, *bardela*. from Rio Grande do Sul, which according to the description is smaller, on the upperside darker and therefore with less grey and rose-coloured scales, also on the underside of the forewing on the red transverse band towards the costa whitish instead of rose-colour, can scarcely be distinguished from *autodyca* according

to my material; on the other hand a ♀-aberration from Rio Grande do Sul with the band more pale red deserves to be named separately as ab. **rosa form. nov.** — **paula subsp. nov.**, from the province of São Paulo, is in both sexes above more plentifully scaled with grey, also at the distal margin of the hindwing in both sexes are large spots of grey scales, the ground-colour of the ♀♀ is not pure black, but black-brown, and the under surface much lighter both in the ground-colour and in the colouring of the red band.

swainsoni. **P. swainsoni** Gray (21 a), from Parana, Santa Catharina and São Paulo, differs from *autodyca* by its larger form, above by a more distinct transverse band on the forewing and by the difference in the grey scaling, which is confined to the inner margin of the forewing and the basal half of the hindwing, and further by a yellow spot at the costal margin of the hindwing. On the under surface of the ♂♂ the red median band present in the *autodyca*-♂♂ is wanting on the posterior part of the wing. Both species fly together in Rio Grande do Sul and São Paulo. — FRUHSTORFER has based the subsp. **phalera** (21 b) on specimens from Rio Grande do Sul and Santa Catharina, but with the exception of the darker colouring of the under surface I have not been able to confirm the characters given by him.

cheops. **P. cheops** Stgr. (21 b), from Chiriqui, has a bluish black upper surface with slight gloss, the ♂ has a median band of yellow scales, a similar one in the anterior part of the cell and sparse yellow scales at the inner margin of the forewing and on the basal part of the hindwing. On the lighter (black-brown) under surface the yellow band of the forewing is much broader and more distinct, at the costal margin of the hindwing stands a yellow band and at the base are two red spots. The ♀ has a broad red band and yellow costal margin on the upperside of the forewing. Both sexes have yellow antennae.

charops. **P. charops** Bdv. (21 b), occurring from Mexico to Panama (Chiriqui), is distinguished from the other forms of this species by copious grey-white (♂) or reddish (♀) dusting at the distal margin of the forewing. The median band of the forewing is brilliant yellow (♂) or red (♀) beneath. Both sexes have on the underside of the hindwing a long yellow stripe at the costal margin and a very small yellow stripe at the base.

subvarians. — **subvarians** Stgr. *i. l.*, from Colombia, has in the ♂ less grey dusting on the upperside, and the median band of the underside is for the most part dull red instead of yellow. In the ♀ the submarginal red dusting is absent from the upperside of the forewing. — **columbica** Fruhst., from Colombia, is distinguished by a general reduction of the grey dusting, which remains more distinct, however, in the middle cell; yellow spots are placed at the discocellular; median band of the forewing beneath yellow. This form appears to be only a ♂-aberration of **cauca** subsp. nov., from the Cauca Valley in North Colombia. In this the grey dusting of the ♂ is uniformly reduced everywhere, the median band is red instead of yellow for more than its basal half, and shows through on the upperside. The ♀♀ have a very broad light red band on both sides of the forewing. — **peruvianus** Stgr. *i. l.*, from Peru, has a broad yellow median band on the upperside of the forewing and distinct grey scaling on the apical part and the inner margin of the forewing; the hindwing has but little grey scaling. The under surface of the forewing has a sharp, sulphur-yellow median band.

meridana. ♀ unknown. — **meridana** Fruhst., from Northern Venezuela, has a strongly darkened upper surface without grey scales in and behind the middle cell and on the distal part of the hindwing, distal part of the median band on the underside of the forewing red. Amongst this form occurs ab. **praemeridana** Fruhst., which has the band of the forewing beneath entirely yellow. — This species has white antennae.

leucodrosime. **P. leucodrosime** Koll. (21 c). With this species, from Colombia, begins the series of those species which have also in the ♂ a red band on the upper surface of the forewing. Ground-colour black, proximal half of the hindwing and basal part of the inner margin of the forewing with blue-white scales, thorax and abdomen with white hairs. The red band of the forewing above ends at the subcostal and is not prolonged basad. The under surface is black-brown, the veins and the stripes between them are black, at the base of the hindwing there are two small red spots. Antennae white. Specimens with the red band much reduced are ab. **reducta** form. nov. — In **bellatrix** Fruhst., from Peru, the red band of the forewing is lighter and is not narrowed towards the margin, on the other hand the blue-white scaling on the proximal part of the wing is reduced, under surface somewhat darker. — **beryllina** Fruhst., from Ecuador, has a narrower and deep red band on the forewing. — **latona** Btlr., from Venezuela, has on the upperside of the forewing only a red spot at the end of the cell instead of the red band. Among this form occur also specimens with entirely black forewing: ab. **unicolor** ab. nov.

callinira. **P. callinira** Stgr. (21 c), from Peru, has black antennae. The upper surface as in *leucodrosime* is scaled with blue-white, the band of the forewing is of uniform breadth and in the middle cell continued somewhat towards the base, the basal half of the costal margin is finely, but sharply yellow, on the under surface of the hindwing the red basal spots are absent. ab. **musia** Fruhst., from North and Central Peru, is larger, the red band much narrowed at both ends and rounded off. — **sabrina** Fruhst., from Colombia, has an essentially narrower red band on the forewing and more abundant blue scaling at the base, at the costal margin of the forewing the red band is tinged with yellowish. — **numatia** Fruhst., from Bolivia, is smaller and paler, the red band broader, above in the middle more copiously scaled with black.

P. callinice *Fldr.* (21 c), from Venezuela, Colombia and South Peru, has likewise black antennae. *callinice*. The upper surface is black brown, the bluish scaling occupies the whole basal half of the hindwing but is completely wanting on the forewing. The light red median band of the forewing is only represented behind the discocellulars by a very small spot, is distally rounded and does not reach the distal margin. The under surface is as in *callinira*, but much lighter. The butterfly flies on forest-paths and is fond of drinking at moist places on the ground.

P. telthusa *Hev.* (21 c), from Peru and Ecuador, differs much from the preceding species. Antennae *telthusa*. white. Upper surface black, with subapical yellowish macular band, small light submarginal spots, bluish white inner-marginal part of the forewing and blue-scaled basal part of the hindwing, which also shows small bluish marginal spots. The under surface is black, the forewing has the pattern of the upperside and the hindwing a small yellow stripe at the costal margin and also three red basal spots. — **magna** *subsp. magna*, *nov.*, from the Lower Amazon (Obidos), is larger, the light area at the inner margin of the forewing is smaller and completely scaled with blue, the blue spots at the distal margin of the hindwing are larger, the under surface is darker and the yellow stripes at the costal margin of the hindwing very small. — **boliviana** *subsp. nov.*, from Bolivia, has a broader and more strongly yellow subapical band on the forewing above and beneath. The light area at the inner margin of the forewing is larger on both surfaces and only scaled with blue at the margins, the blue spots at the distal margin of the hindwing are smaller, the under surface is somewhat lighter (more brown) and the yellow stripes at the costal margin of the hindwing longer and broader.

9. Genus: **Archonias** *Hbn.*

The characters of this genus are rather uncertain, the facies of the butterflies forms the best criterion for deciding as to their genus. The subcostal is four-branched, the 2. branch originates beyond the apex of the cell and the 3. and 4. branches form a short fork in the apex of the wing; yet this character is not constant even in one and the same species. It will be advisable to place in this genus only the *tereas*-like forms which mimic *Papilio*.

A. tereas *Godt.* (= *iulus* *Hbn.*, ♀ = *marcius* *Hbn.*). The specimens from Rio de Janeiro and Espiritu Santo may be regarded as the so-called typical form. It can scarcely be separated from **uniplaga** *Fruhst.*, (21 d), from Rio Grande do Sul and São Paulo. This form is said to have only one white median spot on the forewing, which however among the material before me only occurs in one specimen from Santa Catharina; the remaining eight specimens from Santa Catharina and São Paulo have three median spots, one of which is placed in the cell. The ♀ has always somewhat more white marking on the forewing and more red, of a deeper colour, on the hindwing. — **critias** *Fldr.* (21 d), from Venezuela and Colombia, is very variable as regards the white marking on the forewing, the red marking of the hindwing is more extended and of a deeper tone than in *tereas*. To ab. **hades** *Fruhst.* belong specimens with the forewing entirely black above and to ab. **nigripennis** *Bthr.* entirely black specimens — **approximata** *Bthr.* is the form from Central America. — **papilionides** *Fruhst.*, from Honduras, has somewhat modified white spots on the forewing and three intensively carmine-red spots on the hindwing; beneath the spots on the wings are yellowish. — **regillus** *Fruhst.*, from Ecuador, is smaller than *tereas*, the forewing has two white spots placed one under the other, the hindwing three small pale red, lighter-margined ones. — **archidona** *Fruhst.*, from Ecuador (Balzabamba), has a completely black forewing or at least but little white marking, and on the hindwing above and beneath yellowish or white instead of red spots. — **rosacea** *Bthr.*, from Ecuador (Quito) and Colombia, has light red spots on the upper surface of the hindwing. — "In Santa Catharina *tereas* begins to fly early in September as one of the first heralds of spring, and animates in well-watered valleys almost all the sweet-scented flowering shrubs with its quiet beauty and its delicately coloured garb" (*FRUHSTORFER*).

A. bellona *Cr.* (= ♀ *erycinia* *Cr.*, *brassolis* *F.*, *braselis* *Godt.*), from Guiana, although regarded as a separate species, is probably really another form of *tereas*, which is extraordinarily modified in the wooded west. **A. bellona** is but little different from **negrina** *Fldr.*, from the Rio Negro. The ♂ is black above with large light yellow spots on the forewing and red streaks on the under surface of the hindwing, whilst in the ♀ the upper surface of the hindwing is also for the most part red. — **cutila** *Fruhst.* (21 d), from Ecuador, has large yellow spots on the forewing and three red streaks on the upper surface of the hindwing. — **phaloreia** *Fruhst.*, from Peru, has black upper surface with small yellow spots on the forewing. — **hyrnethe** *Fruhst.* (21 d), from Bolivia, has more rounded wings than the preceding forms, the spots on the forewing are somewhat lighter yellow and a little larger, the upper surface of the hindwing is black, but the under surface has narrow red streaks, a yellow stripe at the costal margin and yellow marginal spots. In the ♀ the hindwing above is for the most part red. — **sabrina** *Fruhst.*, from Argentina (?), has very intensive yellow spots on the forewing, of which the curved one in the cell is very large; the underside of the hindwing is similar to that of *hyrnethe*, the yellow marginal spots are very small. Baron G. von PLESSEN observed this species in large numbers and in both sexes in a thicket, so it may be assumed that the butterflies had emerged in this thicket; hence we may further conclude that the larva is gregarious. The butterflies are fond of settling on leaves.

pharnakia. **A. pharnakia** *Frühst.* (= *archoniaoides* *Stgr. i. l.*) (21 e), from Peru, is very different from all the above mentioned *Archonias*-forms, and is probably a separate species. The upper surface is black-brown with yellow spots on the forewing as on the underside, the hindwing is entirely without markings; ♀ in the middle part of the forewing above and beneath brick-red.

10. Genus: **Charonias** *Rüb.*

For the reasons given under *Archonias* it is necessary to place the following species in a separate genus. In the neurulation there is a slight difference in that the two discocellulars of the forewing are of equal length and the upper discocellular of the hindwing is considerably shorter than the other two. The palpi are somewhat longer and stronger than in *Archonias*. Above all the external appearance is important in determining the genus.

eurytele. **Ch. eurytele** *Hew.* (21 e), from Ecuador and Colombia, is brown on the proximal part of the wing and black on the distal part, in the latter are placed yellow spots; specimens with white spots may be described as ab. **albimaculata** *ab. nov.* The under surface is quite similar to the upper, but there are rather *albimaculata*. large white submarginal spots at the distal margin of the hindwing. — In **lyceas** *Godm. and Salv.*, from *lyceas*. Panama (Bugaba), there is only a streak-shaped spot of the brown colour of the forewing above present at the inner margin, the under surface of the forewing is entirely black. — **dismorphitis** *Btlr.*, from Chiriqui, *dismorphitis*. has the forewing deep black with light yellow spots and the hindwing light brown. — **dismorphina** *Stgr. i. l.*, from Colombia, likewise has the forewing very dark all over, with larger deep yellow spots, the hind- *dismorphina*. wing being dark brown. — **nigrescens** *Godm. and Salv.*, from Guatemala, is a still further darkened form. *nigrescens*. — The ♀♀ are only somewhat larger, otherwise not different.

theano. **Ch. theano** *Bdr.* (21 e), from Brazil (e. g. São Paulo) is black with whitish streak-shaped spots. The ♀ instead of white marks has dark yellow ones in the proximal and sulphur-yellow in the distal part of the wings. The under surface is similarly, but more copiously marked, the hindwing is yellow with black veins and black distal margin in which white spots are placed.

11. Genus: **Appias** *Hbn.*

In the neurulation this genus agrees entirely with *Pieris*, but the ♂♂ have a special characteristic, namely two stiff tufts of hair (secondary sexual organs) on the anal claspers at the underside of the abdomen; the ♀♀ are easily distinguished from those of *Pieris* by the peculiar colouring of the under surface, which is weaker-marked and has a slight pearly gloss. The genus is represented in India by numerous species, some of them beautifully coloured, and also in Africa by several species, but in America there is only one certainly distinct species, which until recently was classed with the genus *Daptonoura*. As the synonymous generic name *Tachyris*, given by Wallace, indicates, the insects belonging to this genus are extraordinarily active. According to the observations of Dr. A. SEITZ the *Appias* (especially *drusilla*) are only equalled in swiftness of flight among the butterflies by the representatives of the Hesperid genus *Spathilepia*; in a few seconds they traverse long distances. They not only fly extremely fast but also manage to take up their nourishment from flowers in the greatest haste. Only in imbibing water from the damp ground, where these insects, particularly the males, sometimes settle in large crowds close together, do they allow themselves time, and engage in this activity for the moment as an amusement.

drusilla. **A. drusilla** *Cr.* (= *ilaire* *Godt.*, *margarita* *Hbn.*, *albunea* *Dalm.*) (21 f) is distributed from Southern Florida to South Brazil, and is common. The ♂ is white above, with slight blackish apical marking on the forewing, sometimes entirely without marking, beneath yellowish white without marking, only with a small yellow stripe at the costal margin of the hindwing. The ♀ is white above on the forewing, on the hindwing yellowish, and has broad black margins, beneath white with a reddish sheen and very weakly developed markings similar to those on the upperside, as well as yellow dusting at the base of both wings, especially the forewing. The specimen figured by W. J. HOLLAND in his *Butterfly Book* on plate XXXV as ♀ is according to the shape of the wings a ♂ with strongly yellowish upper surface and more strongly developed *hollandi*. black marking at the apex and basal part of the forewing; this form deserves special mention as ab. **hol-** *janeira*. **landi** *ab. nov.* — **janeira** *Bönnigh.*, hitherto only observed in the Botanical Gardens at Rio de Janeiro, has also in the male yellow colouring at the base on the underside of the wings; v. BÖNNINGHAUSEN regarded it *poeyi*. as a distinct species. — **poeyi** *Btlr.*, from the Antilles, has in the ♂ no markings above and is somewhat more yellowish beneath; the ♀ has more strongly yellow ground-colour and slighter marginal marking on the hindwing above, the underside is likewise more yellow than in *drusilla*-♀.

12. Genus: **Cathaemia** Hbn.

The forms belonging here were until recently united with *Hesperocharis*, but RADCL. GROTE erected the genus *Unizsa* for them. This name, however, must give way to the older one given by HÜBNER. It is true that the only difference in the neuration is that in *Hesperocharis* the upper discocellular of both wings is angled and has a short spur running into the cell, in *Cathaemia* on the contrary these veins are only slightly curved and have no spurs, but the great difference in the style of marking and the shape of the wings confirms the generic independence of the two.

C. hirlanda Stoll., probably from Surinam, is distinguished from the better known **ninguida** Fruhst. *hirlanda*. (= *hirlanda* Stgr.) (21 f), from Peru, by the broader black distal margin of both wings. — **obnubila** Fruhst., from *ninguida*. South Peru, has the hindwing almost black, so that only the cell and a few postmedian spots remain white. — **fulvinota** Btlr., from Rio de Janeiro, is completely white above except for the yellowish basal part of *fulvinota*. the wings and the black costal margin of the forewing, the under surface is quite similar to that of *hirlanda* except that it has a red-yellow instead of a red marginal band on the hindwing. — **praeclara** Fruhst., from *praeclara*. Espiritu Santo, is in the ♂ of a beautiful light yellow on the upperside of the forewing, on the hindwing lemon-yellow with red band of the under surface showing through slightly, forewing with broad black distal margin, which at the 1. median vein is united with a black band starting from the costal margin, hindwing with narrow black margin, under surface similar to that of *hirlanda*, the black apical spot not joined to the subapical band, but separated from it by a yellow band. In the ♀ the black margin of both wings is broader. — **apicalis** Fruhst., from Ecuador, is intermediate between *ninguida* and *obnubila*. — **helvia** Latr. (21 f), said to *apicalis*. be from Mexico (?), of which only specimens from Colombia are before me, generally regarded as a separate *helvia*. species, is in my opinion also a *hirlanda* form, because I have specimens which unmistakably form a transition. In this form the red marginal band of the hindwing beneath is wanting, yet most specimens have traces of it. The aberration which is suffused with light yellow on the upperside of the forewing and on the underside of the forewing coloured with yellow over the whole surface is named by FRUHSTOEFER *ab. serda*; transitional forms, however, also occur. *serda*.

13. Genus: **Leodonta** Btlr.

The species of this genus were formerly classed with *Perente*. Although the two genera show no essential difference in the neuration and in the organs, they are yet sharply separated by their external appearance. But another character which is doubtless worthy of note consists in the formation of the anal claspers of the ♂♂, which are much smaller in *Leodonta* than in *Perente*. So far seven forms have been described, which have all been regarded as separate species, but I have only been able to recognise in them two species, one of which forms local races. — The butterflies fly over foot-paths and are fond of drinking at moist places on the ground.

L. dysoni Doubl. (21 e), from Venezuela, is the form which has the most white markings on the *dysoni*. upper surface, the hindwing is white with obsolete yellow spots at the base and broad black distal margin, which occupies about $\frac{1}{4}$ of the surface of the wing, at the distal margin are placed larger white spots, the median band on the underside of the hindwing is white with one yellow streak in each marginal cell, and the rest of the hindwing beneath is lighter than in the other forms. — **zenobina** Hopff. (21 e), from Peru *zenobina*. and Bolivia, has a broader black distal margin on the hindwing above and darker distal and basal parts on the hindwing beneath. — **intermedia** subsp. nov., from Northern Colombia (Cauca Valley), is smaller, the *intermedia*. black distal margin of the hindwing is somewhat narrower than in *zenobina* and the basal part darkened, the median band on the under surface of the hindwing is broader and yellow, only the veins being very narrowly whitish, on the upper surface of the forewing in the cell at the point of origin of the 2. median vein there is a white spot, which also beneath is much larger than in the preceding forms. — In **chiriquensis** Stgr., from Chiriqui, the black distal-marginal band of the hindwing reaches the discocellulars and at the distal margin there are larger white spots, the white median band of the forewing is narrower. — **zenobia** Fldr., from Colombia, is a smaller form with yellowish median band on the upperside, the basal *zenobia*. part of the hindwing is black, the light median band on the underside of the hindwing narrower, being interrupted in the middle. — In **tagaste** Fldr. (21 f), from Peru and Ecuador, the upper surface is for the *tagaste*. most part white, the hindwing has only a black margin. — **marginata** Schaus, from Venezuela (Merida), has *marginata*. half the forewing white, and 2 rows of small white subapical spots, the hindwing being similar to that of *dysoni*.

L. tellane Heur. (22 a), from Colombia, is yellow above with broad black margins, in which are *tellane*. placed yellow spots, the proximal part of the hindwing beneath is yellow, the base itself grey-brown.

14. Genus: **Catastieta** Btlr.

The only apparently certain difference in the neuration of this genus from that of *Archonias* consists in the second subcostal vein branching off either immediately at the upper angle of the cell or shortly before or after it. The external appearance of the representatives of this genus differs from that of *Archonias*

to such an extent that their generic separation seems fully justified. Although the *Catasticta*-species exhibit a fairly uniform facies yet they form various groups, which however are mostly connected by transitions. The genus is distributed from Mexico to South Brazil, but has its proper habitat in the mountains of the west. The species doubtless vary considerably according to the locality, whether they also show seasonal forms has not yet been ascertained. According to PAUL HAHNEL the ♂♂ of the *Catasticta*-species have a habit of settling in the sunshine on water-washed stones at the banks of rivers, and drinking so greedily that the water comes out again in drops at the anus at short intervals. Not infrequently they are washed away by the water, which however does not harm them in the least, for immediately afterwards they rise like a water-bird out of the waves, in order to settle anew on the stone where they can reach the refreshing liquid.

notha. **C. notha** Luc. (22a), from Venezuela, is above white with black apical and distal-marginal marking, very similar to the following species, beneath with white forewing, the apex of which is reddish grey, with small yellow stripes, hindwing diffusely red-white with yellow stripes in the cellules, distinct triangular yellow marginal spots and red basal spot.

corcyra. **C. corcyra** Fldr. (22a), from Venezuela and Bolivia, is above very similar to the preceding, except that on the hindwing the dark markings of the under surface show through. Underside of the forewing white with black apex, in which yellow stripes are placed, hindwing yellow with black-brown veins edged with white, black-brown dentate median band and vestiges of a marginal lunate macular band. — In *staudingeri* Btlr., from East Peru, the latter is completely developed. In this form the under surface of the hindwing is much lighter yellow and the black apical marking of the forewing only reaches to the second median vein. The ♀ has broadened black-brown apical marking of the forewing and black-brown spots at the distal margin of the hindwing above.

peris. **C. peris** Hopff. (22a), from Peru, is above white with black apical and subapical marking on the forewing and also a black marginal line on the hindwing. The under surface is white with brownish and yellow markings on the apex of the forewing. The underside of the hindwing is white, with a lunate line at the distal margin and in the middle, as well as similarly coloured markings at the base, where there is also a dark red spot; each area of the wing has a yellow longitudinal stripe. — *innuba* Stgr. i. l., from Bolivia, has yellow ground-colour above and beneath.

eurigania. **C. eurigania** Hew., from Ecuador, is undoubtedly only a local form of *straminea* Btlr. (22a), from *straminea* Peru; the latter is distinguished by deeper yellow ground-colouring, the presence of three subapical yellow spots on the forewing and somewhat different marking at the distal margin of the hindwing. The under surface has the typical *Catasticta*-marking.

theresa. **C. theresa** Btlr. (22a), from Chiriqui, has the outer margin of the forewing concave. The ground-colour is dark brown and the yellow markings are narrower than in *eurigania*. The under surface is similar, but the yellow markings are reduced in favour of the slightly glossy reddish-bluish colouring.

nimbice. **C. nimbice** Bdv. (22b), from Mexico, has in the ♂ straw-yellow, in the ♀ ochre-yellow markings on the upperside. — *bryson* Stgr. i. l. (22b), from Chiriqui and Guatemala, has broadened yellow markings on the upper surface, the under surface is somewhat lighter, especially at the base.

sinapina. **C. sinapina** Btlr., from Peru, resembles *nimbica* on the upper surface, but the median band is more distinctly divided by the veins and the spots of which it is composed are smaller, the submarginal spots of the forewing and the marginal ones of the hindwing are larger, hindwing produced at the anal angle, under surface entirely uniform, ground-colouring mustard-yellow and the veins and markings purple-brown. Only known to me from the description.

pinava. **C. pinava** Dbl. (22b), from Bolivia and Peru, is above similar to the preceding species, but has narrower yellow markings and the wings more rounded. The hindwing beneath is suffused with more glossy white, and consequently lighter. The ♀ has above much lighter yellow, almost white markings.

vapina. **C. vapina** Btlr., from Ecuador, is most closely allied to *pinava*, to which it is very similar on the upper surface. All the pale markings are lighter, more sandy yellow, except those at the distal margin, which are white. On the under surface colouring and markings are very similar to *philotheta*, but all the light areas are larger and sharper, the ground-colouring of the forewing is light chamois, of the hindwing pearly white, suffused with sulphur-yellow on the proximal half, the white marginal markings are as in *manco*, apex and distal margin of the forewing similarly coloured. Only known to me from the description.

colla. **C. colla** Dbl. (22b), from Bolivia and Peru, has above black-brown ground-colour with deep yellow macular median band and a submarginal row of small yellow dots on the forewing, broader yellow median band and some yellow marginal spots on the hindwing. The under surface is very gay on account of its

silver-white, sulphur- and orange-yellow, and also brownish and black spots, the arrangement of which may be seen from the figure. — **jacinta** *Btlr.* (22b), from Bolivia (seasonal form?), has much more yellow on *jacinta*. the upper surface. The under surface is less variegated on account of the almost complete absence of the *plesseni*. silver-white markings. — **plesseni** *subsp. nov.*, discovered by Baron G. v. PLESSEX in Ecuador (Baños), is somewhat smaller than *colla*, and has above lighter yellow median bands and more distinct submarginal spots; beneath all the yellow markings are likewise lighter and the ground-colour of the hindwing purer white, without reddish flush.

C. chelidonis *Hopff.* (22c), from Bolivia, has broader and more distinct yellow markings than **philomene** *Stgr. i. l.*, from Bolivia (seasonal form?). The under surface in both forms is quite similar, only *chelidonis* has more yellow markings on the forewing, particularly in the middle. — The small form from Ecuador with sharper yellow markings may be differentiated as **aequatorialis** *form. nov.*

C. hopfferi *Stgr. i. l.* (= *pinava* *Ittr.*, nec *Dbl.*) (22c), from Bolivia, is much smaller than the preceding species, but the submarginal yellow spots are much larger and both wings have small yellow marginal spots. On the underside of the hindwing the median markings are separated from the marginal spots by a sharply defined band of silver-white heart-shaped spots, the yellow markings are not orange, but sulphur-yellow. — Specimens with darkened upper surface are in the market as forma **obscurior** *Stgr. i. l.*

C. teutanis *Hew.* (22c), from Peru and Ecuador, gives on the upper surface the impression of a small *Pareronia*. Upper surface white, on the basal part of the forewing and the whole of the hindwing bluish white on account of the dark colouring of the under surface showing through, the apical half of the forewing black with small bluish white subapical and submarginal streaks, the hindwing with rather broad, deeply indented black distal margin. Under surface with the exception of the middle part of the forewing brown-black with slight yellow marginal and submarginal markings and two dark red basal spots on the hindwing.

C. ctemene *Hew.* (22c), from Ecuador, has the apex of the forewing produced. Upper surface white with black-brown apical and basal parts and black-brown marginal spots on the forewing; in the dark apex of the forewing are placed small white subapical spots. The underside of the forewing is white, that of the hindwing bluish brown with diffuse *Catantacta*-markings.

C. prioneris *Hopff.* (22c), from Peru, is white above with black-brown markings at the margin and at the base. Under surface white with bluish brown and sulphur-yellow *Catantacta*-markings and two red basal spots on the hindwing. ♀ has much broader marginal markings, particularly on the hindwing. — **caucana** *subsp. nov.*, from Cauca in Colombia, is distinguished by the want of the white submarginal spots of the forewing and slight black marking at the distal margin of the hindwing. The under surface is paler. The ♀♀ have above larger white spots at the discocellular than *prioneris*-♀♀.

C. sisamnius *F.*, from Peru, has black upper surface, a broad white median band and white marginal and submarginal dots and spots. The markings of the under surface correspond to those of the upper, median band yellowish white with small yellow stripes, marginal and basal areas black-brown with small marginal and submarginal spots and two red basal spots on the hindwing. — **telasco** *Luc.*, from Chiriqui, has on the hindwing narrower black distal margin and the white submarginal spots on the forewing are larger, the median band of the forewing is narrower and the under surface somewhat lighter. — **pitana** *Fldr.* (22c), from Colombia, has the median band still broader and very sharply defined, being in the ♂ white, in the ♀ white or yellowish; ♀♀ with lemon-yellow median band and spots of the same colour may be distinguished as ♀-f. **flava** *form. nov.*

C. bithys *Hbn.* (22d) occurs from Mexico to South Brazil. Upperside black-brown with narrow whitish macular median band, small white marginal and submarginal spots; sometimes one or the other row is wanting. Underside with small yellow stripes in the white median band of the hindwing, marginal part reddish black-brown, with small marginal and submarginal yellow spots edged with black. ♀ not different.

C. troezene *Fldr.* (22d), from Colombia, has black-brown upper surface with white macular median band, darkly dusted over, distinct submarginal and indistinct (in the forewing sometimes absent) marginal spots which on the hindwing are small but distinct. Under surface much marked with sulphur-yellow.

C. troezenides *Stgr. i. l.* (22d), from Colombia, though very similar to *troezene* beneath, has less yellow marking and broader black-brown marginal marking. Above differing somewhat in the greater part of the hindwing being white. In contrast to the hindwing the forewing shows less white markings than *troezene*.

C. hebra *Luc.* (22d), from Colombia, is similar to *troezenides* above, but the black margin of the hindwing is broader and dentate, the under surface however is rather different through the want of sharp *Catantacta*-marking. The underside of the hindwing is reddish brown with light submarginal and median bands, distinct triangular sulphur-yellow marginal spots, oblong sulphur-yellow submarginal ones and sulphur-yellow stripes in the proximal part of the wing.

strigosa. **C. strigosa** *Btlr.*, from Peru, is in form, size and general appearance like *hebra*, deep olive-brown, the last third of the middle cell of the forewing shows sparse sulphur-yellow scaling, the cell is surrounded by a row of oblong, pointed sulphur-yellow-brown streaks, the outer part of the first six streaks is divided by the ground-colour, hindwing sulphur-yellow-brown, but the veins and the distal margin olive-brown, three elongated light yellow spots bound the 2. to 4. interneural stripes. Under surface similar to that of *ctemene*, but the yellow spot on the forewing divided into narrow streaks by the broadly brown-edged veins. Only known to me from the description.

crowleyi. **C. crowleyi** *Btlr.*, from Venezuela (Monte Sierra and Culata), is similar to *strigosa*. Upperside dark purple-brown with whitish ash-grey areas and spots, the distal margin of the hindwing and the veins are sharply prominent; an orange-yellow spot at each side of the prothorax; under surface almost as in *actinotis*, but the hindwing of light reddish brown colour, without sharp median band, the yellow spots only edged with dark brown marks. Only known to me from the description.

semiramis. **C. semiramis** *Luc.* (22d), from Colombia, is above obscure grey-black with indistinct yellowish white submarginal and central spots, but beneath brilliantly marked. The hindwing is remarkable for the abundant sulphur-yellow markings, which are paler on the forewing, and the sharp black and snow-white markings.

niobe. **C. niobe** *Stgr. i. l.* (22d), from Bolivia, is above black-brown with indistinct yellowish submarginal and central spots on the forewing and light subbasal band on the hindwing. The ground-colour of the hindwing beneath is a light sulphur-yellow, on which the black and the dark sulphur-yellow, black-edged markings stand out well. The forewing has black-brown ground-colour with light marginal, submarginal and central spots, which are sulphur-yellow in the anterior part and white in the posterior.

suasa. **C. suasa** *Stgr. i. l.* (22e), from Bolivia, has very dark, black-brown upper surface, with obsolete whitish submarginal and central spots. The under surface of the hindwing is very variegated, with silver-white, sulphur-yellow, reddish brown and black-brown markings. The under surface of the forewing has black-brown ground-colour and white submarginal and central spots, as well as very small, white, anteriorly yellow, oblong marginal spots. — **suasella** *subsp. ncv.*, from Peru, is above much lighter (yellowish grey) and beneath much less sharply marked; the light markings on the underside of the forewing are yellowish and much more extended in the middle.

modesta. **C. modesta** *Luc.* (22e), from Peru, has the upper surface grey-brown with slight obsolescent light submarginal and central markings. The under surface of the forewing is yellowish with brown and dark yellow marginal markings, the underside of the hindwing is reddish brown with diffuse silver-white submarginal and central bands and dark yellow markings. — **actinotis** *Btlr.* (22e ♀), from Costa Rica and Chiriqui, has more extended yellowish markings above and darker coloured under surface. The ♀ is above black-brown with yellow disc on the forewing, which is intersected by the dark veins; the underside the same.

manco. **C. manco** *Dbl.* (= incerta *Dogn.*) (22e), from Bolivia, has black-brown upper surface with submarginal and central markings on the forewing, and on the hindwing marginal and submarginal markings, all ashy grey, as is also the base. The underside of the hindwing is silver-white with narrow black markings and broad sulphur-yellow ones. The ground-colour of the forewing beneath is impure white with a marginal lunate line, which is sharp and black in the anterior part, black-brown and not sharp in the posterior, the black-brown submarginal band and similar coloured basal part with light stripes; in the apex there are sulphur-yellow spots. — **philotheta** *Fldr.*, from Colombia, is above somewhat more yellow, on the underside of the hindwing less yellow, but more strongly marked with black. — **philoscia** *Fldr.*, from Venezuela, is less yellow on the whole upperside and on the underside of the forewing still more yellowish; can scarcely be separated from *philotheta*.

anaitis. **C. anaitis** *Hew.* (22e), from Ecuador, has ash-grey-yellowish upper surface with black-brown margins and small light submarginal spots. The under surface is silver-white with sulphur-yellow, black and brownish markings.

reducta. **C. reducta** *Btlr.*, from Ecuador, is above like *anaitis*, but much smaller and all the spots of the upperside are ochre-yellow, irregularly coloured with purple-brown, the veins are much more broadly blackish, the hindwing has a row of small white marginal spots, the macular band on the underside of the forewing is lighter ochre-yellow and the forewing is more falcate. — **boliviana** *Btlr.* differs in the light ochre-coloured spots on the under surface, which shows scarcely any admixture of dark. Only known to me from the description.

sordida. **C. sordida** *Btlr.*, from Bolivia, has the general colouring of *anaitis*, but is less yellow, the spot at the end of the cell and the spots of the central row of the forewing next to the costal margin are smaller. Distal margin of the hindwing blackish, occupying almost half the wing and crossed by spots of the ground-colour. Beneath all the light marks are reduced and the brown areas much broader, the light bands are cream-coloured, not pure white, and the yellow stripes and spots of a deeper colour.

C. flisa *H.-Schöff.* (22e), from Colombia, has black-brown upper surface with white macular median *flisa*. band, submarginal and very small marginal white spots; in the ♀ the anal area of the hindwing is yellow. The under surface is black-brown with a white macular median band, in which on the hindwing yellow spots are placed, the marginal spots being present as above, but whitish yellow.

C. chrysolopha *Koll.* (= *xeque Mengel*) (22f), from Ecuador, has black upper surface, on the *chrysolopha*. forewing a white macular median band and small diffuse submarginal white spots, the hindwing has a median band which is bright ochre-yellow in the middle and white anteriorly, and likewise small, diffuse submarginal white spots. The under surface of the hindwing is yellowish white with sulphur-yellow and black markings. The ♀ has rounder wings, is paler above and beneath and has on the hindwing also small light spots.

C. apaturina *Bth.* (22f), from Ecuador, is very similar to the preceding species, but has smaller *apaturina*. white spots and on the hindwing a narrower and light yellow median band. The under surface of the hindwing has almost snow-white ground-colour and ash-grey submarginal markings and more black markings in the middle.

C. toca *Dbl.* (22f), from Bolivia and Colombia, has black upper surface with white macular median *toca*. band and diffuse white submarginal spots. Under surface of the hindwing white with black marginal band of lunate spots and black median band composed of wedge-shaped spots, and also black basal markings; in each cellule is a sulphur-yellow streak. Under surface of the forewing black with white submarginal and median bands as well as yellow marginal spots. — **detrita** *form nov.*, from the Upper Amazon, is much *detrita*. paler above and beneath.

C. scaeva *Stgr. i. l.* (22f), from Peru. Upperside dark brown with yellow or yellowish macular *scaeva*. median band and submarginal spots of the same colour, underside paler yellow than in *toca* with brownish and (particularly on the hindwing) somewhat different markings; the line at the margin is composed of acute triangles.

C. tomyris *Fldr.* (22f), from Colombia and Venezuela, is above similar to *toca*, but larger. Upper *tomyris*. surface black with white macular median band and small white submarginal spots on the forewing, hindwing with yellowish median band. Under surface of the forewing black with submarginal and median macular bands and yellow marginal spots. Hindwing light yellow with black lines of lunate markings at the distal margin, black central and basal spots and a sulphur-yellow stripe in each cellule. ♀ not different. — **tamina** *tamina*. *Stgr. i. l.*, from Bolivia, has above a broader median band on both wings and on the under surface of the hindwing reddish-bluish colouring at the distal margin and in the basal area, with pure white ground-colour.

C. cora *Luc.* (= *zancle Fldr.*) (22f,g), from Venezuela and Peru, is above dark grey with marginal *cora*. and submarginal black bands. The under surface of the forewing has submarginal and median white macular bands with small yellow spots and yellowish white marginal spots. The under surface of the hindwing is marked with a confusion of white, yellow, black, brown and bluish.

C. uricoecheae *Fldr.* (22f), from Colombia, one of the most beautiful species of the genus, is very *uricoecheae*. similar to *cora* on the upperside of the forewing, but has dark red hindwing with black distal margin and black macular median band. The under surface is also very similar to that of *cora*, but much lighter.

C. cinerea *Bth.*, habitat unknown. Forewing above ashy grey, costal margin and veins broadly *cinerea*. black, distal quarter of the wing occupied by a broad black margin, in which are placed a row of whitish green spots and a row of very small white marginal spots, basal half of the hindwing ashy grey, irregularly scaled with black, distal half black with a row of whitish grey spots and a row of small sulphur-yellow marginal spots. Body blackish, palpi with two white lateral lines, throat with a small yellow spot at each side. Under surface very similar to that of *uricoecheae*, but the grey areas more slate-coloured, the yellow marks deeper in colour, all the light markings sharper and those on the forewing broader. Only known to me from the description.

C. vulnerata *Bth.*, from Ecuador, is similar to *uricoecheae*, but the basal area of the forewing also *vulnerata*. is red, the median band narrower, the red of the hindwing more restricted and greyer, the median bands are smaller, lighter red and diffuse, the inner margin is whitish. On the under surface the markings are sharper, the yellow marks more glossy, the grey central band of the hindwing is fairly straight on its inner side and is on that account broader, its white and yellow borders are narrower, the marginal spots broader, somewhat less angled. Only known to me from the description.

C. tricolor *Bth.*, from Ecuador, is also similar to *uricoecheae*, but all the spots on the upper surface *tricolor*. of the forewing are glossy lemon-yellow, the scarlet of the hindwing is less brilliant, the spot towards the base more reduced, a row of yellow marginal spots present. On the under surface the white and yellow markings are so much reduced that the ground-colour appears grey.

C. paradoxa *Stgr. i. l.* (22g), from Peru, is likewise a very beautiful species. Underside shiny black *paradoxa*. with light yellow submarginal and central spots on the forewing and bright yellow median band and submarginal spots on the hindwing. Under surface of the forewing black with submarginal and median white

macular band and small yellow marginal spots. Under surface of the hindwing white with black marginal line and black lunate line before it, black median sagittate spots and markings of the same colour in the basal area, all the black markings edged with pale ochre-yellow and small ochre-yellow stripes in all the cellules.

teutila. **C. teutila** *Dbl.* (= *sebennica* *Luc.*) (22 g). Sexes rather different. Upper surface glossy blue-black, ♂ with narrow white median band sprinkled with dark, and small marginal and submarginal spots of the same colour, in the ♀ the median band at least double as broad and dark yellow. Under surface grey-black, forewing with the markings as above and small yellow marginal spots, hindwing with yellow, white and black spots. From Mexico.

marcapita. **C. marcapita** *Thieme i. l.* (22 g), from Bolivia, has the forewing black above with wedge-shaped central yellow spot and yellow submarginal spots, upper surface of the hindwing yellow with black marginal lunate line, blackish, diffuse central spots and narrowly black veins. Under surface yellow with black marginal lunate line on both wings, black submarginal band and blackish basal part of the forewing, black wedge-spots and black markings in the basal part of the hindwing.

clara. **C. clara** *spec. nov.* (22 g), from Ecuador, has the upperside of the forewing light yellow with broad, glossy black margin, in which are placed a row of light yellow submarginal spots and two light yellow spots at the costal margin on the discocellulars. Upper surface of the hindwing light sulphur-yellow, strongly dentate, the dentition edged with black and the veins narrowly black, basal part of both wings likewise black. Under surface of the forewing white with black marginal and submarginal dentate markings, small yellow spots in the apex, the discocellulars and the basal area black. Hindwing yellow with narrow black marginal, medial and basal markings, all the veins narrowly black.

eximia. **C. eximia** *spec. nov.* (22 g), from Bolivia, is similar to the preceding species, but smaller, hindwing likewise dentate, though not so strongly. Above on both wings with larger black basal area, forewing light yellow with black marginal and submarginal bands as well as black median spot, hindwing deeper yellow with dentate black marginal band and submarginal black spots. Under surface of the forewing yellower, that of the hindwing lighter, the latter with less deeply dentate black markings, likewise all the veins narrowly black.

radiata. **C. radiata** *Koll.*, from Colombia, is similar to *nimbice*, but yellower, the under surface of the hindwing is much marked with red, and in the centre of the hindwing are two white spots.

emeris. **C. emeris** *Bdr.* Size and shape as *nimbice*. Forewing whitish yellow with blackish, proximally dentate margin, the apex uniformly blackish, a small blackish streak at the discocellular, joined to a larger spot at the apex. Hindwing ochre-yellow, distal margin with a row of small, wedge-shaped black spots along the veins. Under surface of the forewing as the upper, but with a row of yellow spots at the margin. Under surface of the hindwing blackish with a row of yellow marginal spots and ten or eleven white spots marked with yellow, the largest of which fills up the whole of the cell, a large blood-red spot at the base. Chile and Brazil. — Only known to me from the description. This and the preceding species might well be placed after *nimbice*.

susiana. **C. susiana** *Hopff.* differs from *chelidonis* by the longer, narrower forewing, which has exactly the same shape as in *nimbice*, and further by the ochre-yellow spots and bands of *chelidonis* being white, as well as by the form of the discal band. The latter is considerably narrowed in *susiana*, especially in the forewing, where it is only half as broad as in *chelidonis* and more divided into spots, the veins being broader. Its white colour, which in the forewing is dusted with black atoms, has in the hindwing a slightly yellowish tinge. The marginal dots at the end of the internervular folds, which are only indicated in *chelidonis*, here become distinct but very small white triangles, on the other hand the small white spot in the cell is extremely minute and indistinct. — Only known to me from the description; might be placed after *chelidonis*.

alma. **C. alma** *Hopff.*, from Bolivia, is rather unlike the other species on the upperside. It is distinguished by its yellowish white ground-colour, by the deep black veins of both wings, by the broadly black costal margin of the forewing, which occupies the greater part of the cell and of the base, and by the distal margin of the forewing, which is broad at the apex, narrows behind and is proximally bounded by a sharp, straight line and adorned in its whole length with small, fine, wedge-shaped yellowish white spots, whilst the rather broad black distal margin of the hindwing mostly shows yellowish white dots between the veins; the under surface of the hindwing resembles that of *telasco* and *pitana* *Fldr.*, but its markings are much more diffuse and indistinct. — Only known to me from the description. Might well be placed after *sisamnis*.

suadela. **C. suadela** *Hopff.*, from Bolivia, has the forewing broader than in *suasa*, the ground-colour of the upper surface is darker, the median macular band reduced to small obsolescent spots, the submarginal spots are very small, dot-like, but sharp, on the hindwing the median band is completely obsolete, the submarginal spots are very small and indistinct. The under surface has smaller white spots and less yellow markings. Should be inserted after *suasa*.

15. Genus: **Daptonoura** Btlr.

The species of this genus resemble *Appias*, but do not show such strong sexual dimorphism. The secondary sexual character peculiar to the *Appias*-♂♂ (tuft of hair on the underside of the abdomen) is wanting in those of *Daptonoura*. In the neuration this genus agrees with *Pieris* except in the shape of the precostal, which is curved proximad. This genus is confined to tropical America. Recently the name *Melete Swains.* has been employed for this genus, but it would be better to continue to use the well-known name *Daptonoura* instead. *Heliochroma* Btlr. appears to belong here. The species of *Daptonoura* are extraordinarily prone to the formation of local and aberrational as well as seasonal forms, but it is very difficult correctly to fix the limits of either the species or the individual forms. The butterflies, which are very common locally, love the shade of the woods, are fond of congregating at water and have a slow, gentle flight. They fly principally in December to January, singly all through the summer.

D. lycimnia Cr. (= *flippantha* F.) (23a) presumably comes from Surinam; the form from Venezuela, *lycimnia*, a specimen of which is figured, is probably not essentially different. Upper surface white with black apical and distal margin of the forewing and narrow ones of the same colour on the hindwing; sometimes a black spot in the middle of the costal margin of the forewing. Under surface yellow with broader black-brown distal margin and a black-brown spot at the costal margin of the forewing on the discocellulars; ground-colour yellow, lighter posteriorly on the forewing. — **harti** Btlr., from Trinidad, is smaller than *curymnia harti*. *Fldr.*, has the distal margin of the forewing more concave and the marginal band somewhat narrower, especially behind the 2. median vein; the hindwing sulphur-yellow, the dark brown distal margin very narrow; ground-colour of the under surface glossy canary-yellow, the basal area deep orange. The ♀ differs but little. — **phazania** Fruhst., from Bahia, comes between *lycimnia* and *pantoporia* Hbn. — **pantoporia** Hbn., *phazania*, from South Brazil, is a very variable form; it has the distal margin of the hindwing sprinkled with yellow *pantoporia*. or sometimes only a narrow black marginal line. It includes the following forms: ♀-f. **fiora** Fruhst. (23d), *fiora*. with dark yellow ground-colour on both surfaces, broader marginal bands and larger spots in the distal margin of the hindwing above; ♀-f. **pertho** Fruhst., with pure white forewing and dark lemon-yellow *pertho*. hindwing margined with bright red. — **limnoria** Godt. forms the transition to *pantoporia* Hbn. (from Espiritu *limnoria*. Santo and Rio de Janeiro), which again is only a little different from **petronia** Fruhst., from Santa Catharina, *petronia*. Theresopolis and Rio Capivary. Upper surface of the forewing slightly yellowish white with narrow black apical and distal-marginal markings, the hindwing light sulphur-yellow with very narrow black margin. Under surface deeper yellow with broader dark brown distal margin and spots of the same colour at the middle of the costal margin of the forewing; as always, the posterior area of the forewing is much lighter, almost white. With it occurs ♀-f. **daulia** Fruhst., with the forewing white above instead of light yellow. — *daulia*. **paulista** Fruhst., from São Paulo, has broader black apical and distal-marginal markings on the forewing, *paulista*. pure white upper surface and straw-yellow colour on the under surface. But ♂♂ also occur in which the upperside of the hindwing is a beautiful lemon-yellow and the underside almost the same, but deeper yellow: **paula** form nov. (23a). The ♀♀ vary likewise; if the almost white ♀♀ are referred to *paulista*, the strongly *paula*. yellow coloured ♀♀ with broader black markings must be treated as *paula*-♀♀. — **gargaphia** Fruhst., from *gargaphia*. Rio Grande do Sul, is smaller than *petronia*, has the brown-black distal margin of the hindwing scarcely visible in the ♂ and only about 1 mm. broad in the ♀ and narrower markings at the apex and distal margin of the forewing. Under surface in the ♂ whitish yellow, in the ♀ pale straw-colour; rare. Among it occurs: f. **amarella** Fruhst., entirely yellow in both sexes, also the ♂ with black cell-spot on the forewing. — *amarella*. **calymnia** Fldr. (= *leucadia* Fldr.), from the Rio Negro, is yellow and has a broad distal margin to both *calymnia*. wings above and beneath and in the margin of the hindwing 4 yellow spots; f. **theodora** Fruhst., the rainy- *theodora*. season form, is more beautiful yellow, has still broader dark margins, is suffused with light yellow on the basal half of the hindwing above and the underside, with the exception of the posterior half of the forewing, is almost canary-yellow. — **marica** Fruhst. (= *leucadia* Stgr.), from the Upper Amazon, has very broad *marica*. apical border and more or less yellowish ground-colour, also very narrow distal margin of the hindwing. f. **moesia** Fruhst. differs from it in the much broader distal border of both wings. — **euryminia** Fldr., *moesia*. from Colombia, has above mostly an apical spot which is almost rectilinear towards the base, and very narrow *euryminia*. black distal margin on the hindwing. The under surface is sulphur-yellow. The dry-season form, **asta** Fruhst., *asta*. has narrower and more deeply incised apical spot on the forewing, yellowish instead of white upper surface and pale ochre-yellow under surface. — **aelia** Fldr., from Ecuador and Colombia, has the upper surface *aelia*. white with rather broad apical spot, unevenly defined proximally, and very narrow black margin on the hindwing. The under surface is greenish yellow with conspicuous ochre-yellow basal spot on the hindwing. — **huebneri** Btlr. (23d), from Brazil (Leopoldina), is smaller than *limnoria*, the black apical margin narrower, *huebneri*. regularly dentate proximally, the hindwing is glossy sulphur-yellow with broad orange-yellow, black-edged distal margin. The ♀ is likewise smaller than *limnoria*, the median spot is sometimes connected by a stripe with the distal margin, the hindwing as in the ♂, but the orange-yellow distal margin broader. — **napona** *napona*. Fruhst., from Ecuador (Rio Napo), is larger than *aelia*, distal margin of both wings broader, that of the hindwing as in *moesia*, showing through from the underside, in the ♂ the apical third of the forewing beneath

light yellow like the hindwing, in the ♀ the forewing pale yellowish, the hindwing sulphur-yellow, the black distal margin with five diffuse canary-yellow spots, under surface of the forewing sulphur-yellow, of the *pistoria*. hindwing canary-yellow. ♂-f. *pistoria* *Fruhst.*, from the Rio Napo (Ecuador), has still broader distal margin of both wings and pure white under surface. In ♂-f. *latilimbata* *Btlr.*, from Ecuador, the distal margin of *hypoxantha*. both wings is broad and brown. — *hypoxantha* *subsp. nov.*, from Cuba, is smaller, has narrower black *palaestra*. margins and yellow under surface. — *palaestra* *Hopff.*, from Peru (Pozuzo), has deep black apical third, regularly defined proximally, narrow, sometimes extremely narrow black margin, pure white upper surface and very light yellow under surface with broader distal margin on the hindwing. With it occurs f. *ped-* *pedrosina*. *maeotis*. *rosina* *Btlr.*, with the under surface completely white. — *maeotis* *Fruhst.*, from Peru, has the wings narrower. Upper surface in both sexes entirely white, ♂ with obliquely placed black apical spot, which extends to the 1. median vein, ♀ with rectangular black median spot on the forewing, under surface light ochre-yellow. Among them occur the following aberrant forms: *iphigenia* *Fruhst.*, with broader, deep black apical spot, wings on both sides pure white, ♂ with thread-like black distal margin, widened into small spots at the middle veins, ♀ with broad black discocellular on the forewing and broader distal margin on the hindwing. *velia*. wing, marked with five white dots, under surface with grey-black distal margin on both wings; *velia* *Fruhst.*, from Tarapoto, has the shape of *maeotis*, ♂ above purer white with equally broad, deep black distal margin on both wings above and beneath as in *iphigenia*, under surface of the forewing pure white except the subapical area, hindwing above beautiful light yellow; *radiata* *Fruhst.*, from Tarapoto, has the apex of the forewing slightly rounded, upper surface in the ♂ yellowish white, distal margin moderately broad, hindwing above yellowish, distal margin brown, running off proximally into fine streaks along the veins. — *myrtis* *Fruhst.* (= *lycimnia* *Stgr.*), from South Peru (Cuzco), has the upper surface white with narrow black apical part and also narrow black margin on the hindwing, underside of the hindwing lemon-yellow, margin grey-brown. — *donata* *Fruhst.*, from Bolivia (Coroico), recalls *peruviana* *Luc.* Upper surface white, hindwing especially at the inner angle slightly suffused with light yellow; under surface similar to *maeotis*, underside of the hindwing and (as usual) the costal margin of the forewing canary-yellow, apical spot narrow, black-brown, proximally strongly undulate, black cell-spot pointed posteriorly, hindwing with very narrow black marginal line, which only at the veins assumes the form of small pointed teeth; probably a dry-season form. *bianca*. f. *bianca* *Fruhst.*, from Bolivia (Yungas de la Paz), is above entirely white without any yellowish tinge, with extended deep black apical spot and the distal margin of the hindwing scarcely 1 mm. broad, under surface pure white with pale yellowish subapical area and the anterior half of the hindwing slightly suffused with yellow; distal margin grey, on the hindwing about 2 mm. broad, cell-spot distinct. — *pseudomyrtis* *Fruhst.*, from Yungas de la Paz, recalls *maeotis* and in the shape of the wings *aelia* and *myrtis*, but differs from *myrtis* by a somewhat more extended black distal margin on both wings and by the apical spot on the underside of the forewing being brown instead of black. — *monica* *Fruhst.*, from Bolivia, recalls *iphigenia* by the very broad apical margin of the forewing and the ventricose projection in the middle of the hindwing; the dull chalk-white hindwing has a light yellow distal margin about 2 mm. broad, which is adorned with some black spots. Under surface with brown distal margin and triangular spot at the apex of the cell of the forewing, otherwise washed-out straw-yellow. — *leucadia* *Fldr.* (23a), from the Rio Negro and Bolivia, is white above, with moderately broad black apical spot on the forewing and very narrow distal margin on the hindwing; the black median spot of the forewing shows through somewhat above; underside of the forewing light sulphur-yellow, darker at the costal margin, hindwing light ochre-yellow, the narrow distal margin of the hindwing, the apical and the oblong median spot as well as the costal margin of the forewing are grey-black.

peruviana. **D. peruviana** *Luc.* (23a), from Peru (Pozuzo), occurring up to 10,000 ft., has white upper surface, a narrow, sharply dentate apical spot on the forewing and very narrow, sharp distal margin on the hindwing; under surface whitish yellow with slight gloss, sharp black veins on the hindwing, diffuse apical spot and similarly indistinct discocellular on the forewing. f. *yolanda* *Fruhst.*, from Peru (Chanchamayo), is *galatia*. small, has larger black apical spot, and the under surface of the hindwing is straw-yellow. — *galatia* *Fruhst.*, from Bolivia, has the upper surface yellowish, the black apical spot reduced and the under surface almost without markings except for the black veins of the hindwing, only the apex of the forewing being slightly tinged with grey. — *regnidas* *Fruhst.* (23c), from Ecuador, shows extended black apical margin of the forewing, which, however, is more feebly dentate. ♀ orange-yellow.

laria. **D. laria** *Fldr.* is the Colombian form of *louisella* *Fruhst.* (23a), from Peru, from which it differs *louisella*. but little. Both, as also the following Bolivian form, are probably only forms of *peruviana*. In *louisella* the upper surface is pure white, the not very broad apical spot of the forewing and the sharp and very narrow distal margin of the hindwing are deep black; the under surface of the forewing is yellowish white with grey-black apical spot, the hindwing is somewhat darker yellowish with ochre-yellow basal spot, grey-black marginal line and the extremities of the veins black. — *boliviana* *Fruhst.*, from Bolivia, has the wings still more rounded than *louisella*, the apical spot less narrow and more strongly dentate, hindwing with scarcely perceptible black distal margin, ground-colour pure white, underside with light grey-brown apical spot, hindwing with narrow black marginal line and the extremities of the veins slightly tinged with black.

D. polyhymnia *Fldr.* (= *phaenna Fruhst.*) (23b), from Colombia, is lemon-yellow above with broad black margins, the discocellular of the forewing is slightly suffused with black, under surface deeper yellow with broader grey-black margins, in which are placed diffuse yellow spots, rather broad grey-black discocellular spot and similar costal margin of the forewing, as well as ochre-yellow basal spot on the hindwing. *polyhymnia*.

D. isandra *Bdr.* (23b), from Mexico, is impure white above with small grey-black distal-marginal markings on the forewing. Under surface of the hindwing light ochre-yellow with deep ochre-yellow basal spot, forewing somewhat lighter, in the posterior part almost white, with grey scaling on the discocellular: ♀ light orange-yellow. — FRUHSTORFER has named the Honduras form **kleta**. Its ♀♀ are above pale yellowish white, beneath either light canary- or ochre-yellow. *isandra*. *kleta*.

D. florinda *Btlr.* (= *chiricana Stgr.*) (23b), from Veragua and Chiriqui, has somewhat darker yellow ground-colour than *polyhymnia*, very narrow black apical and distal-marginal markings on the forewing and black marginal line on the hindwing. The under surface is deeper yellow with broader black distal margin on the forewing, in which yellow spots are placed, similar black marginal band on the hindwing and black discocellular on the forewing. The female has broader marginal markings and the hindwing ochre-yellow above and beneath. — **monstrosa** *Btlr.* (= *panamensis Stgr.*), from Veragua and Panama, has the upper surface of the forewing white in the ♂, in the ♀ the hindwing somewhat ochre-yellow. Larva according to H. RIBBE similar to that of *Gonepteryx rhamni*, lives on the calabash tree. — **anceps** *Stgr.*, from Chiriqui, has in the ♂ only a yellowish tinge at the inner angle, the hindwing otherwise white, the ♀ has dull yellow hindwing. — **chagris** *Stgr.*, from San Juan on the Rio Chagres, has the forewing white beneath with yellow costal margin, the ♀ has larger yellow spots in the black distal margin of the hindwing. *florinda*. *monstrosa*. *anceps*. *chagris*.

D. limbata *Ky.*, from Ecuador, is white in the female, ash-grey at the base and the costal margin of the forewing, the brown distal margin reaches to the anal angle, forewing with narrow ash-grey margin; under surface white, without spots, hindwing somewhat yellowish, club of the antenna spotted with yellow. ♂ unknown. *limbata*.

D. leucanthe *Fldr.*, from Ecuador and Colombia, differs from **inaequalis** *Btlr.*, from Bolivia and Peru, by its larger size. In *inaequalis* the distal margin of the forewing is straighter, the black apical margin narrower and proximally dentate, only the fringes (not the margin also) of the hindwing are blackish. ♂ above white, ♀ glossy orange, at the costal margin and in the cell of the forewing canary-yellow, beneath the apical area of the forewing and the whole of the hindwing are ochre-yellow, the ♀ is beneath saffron-yellow. *leucanthe*. *inaequalis*.

D. salacia *Godt.* (= *vectclusa Btlr.*) (23c,d), from Mexico, is above white with narrow black apical margin on the forewing and similar marginal line on the hindwing, at the costal margin of the forewing is a subapical black spot, the markings of the under surface show through somewhat. The under surface of the hindwing is yellow with brown distal margin and a similarly coloured median band, which extends from the costal margin to beyond the 1. median vein, becoming gradually narrower, the forewing is white, with ochre-yellow basal area, a large subapical yellow spot which is bounded by the brown apical marking and proximally by a diffuse spot, and brown discocellular. The ♀ is of more compact shape, with paler ground-colour above and beneath and more developed brown markings (only known to me from figures). — **cubana** *Fruhst.*, from Cuba, is above purer white, on the under surface of the hindwing purer yellow, and has on the forewing less black-brown markings in the ♀, while on the other hand at the distal margin of the hindwing, especially above, they are somewhat broader. *salacia*. *cubana*.

D. idiotica *Btlr.* (23c) (locality unknown), for which BUTLER has erected the genus *Heliochroma* and which is only known to me from the figure, probably belongs in this genus (not to *Hesperocharis*). Upper surface of the forewing lemon-yellow, of the hindwing orange-yellow, under surface likewise orange-yellow except for the yellow posterior part of the forewing; no markings on the under surface of the hindwing except two small brownish spots at the costal margin; body blackish. *idiotica*.

16. Genus: **Mathania** Oberth.

This genus differs sufficiently from *Pieris* and *Daptonoura* not only in the peculiar contour of the wings but also in neuration. The 2. subcostal vein does not arise as in *Daptonoura* at the upper angle of the cell, but far beyond it, not far from the apex: *Mathania* further differs from *Pieris* by the subcostal being only four-branched and by the precostal being curved proximad. The palpi are strikingly hairy. The butterflies have mostly a leaf-like under surface. They appear to be purely inhabitants either of the high mountains or of districts in western South America with temperate climate.

M. leucothea *Molina* (= *gayi Blanch.*) (23b), from Chile, is the most like the *Daptonoura*-species. The upper surface is pure white, the under surface yellowish white with more strongly yellowish apex to the forewing and more or less inconspicuous dark clouded markings on the hindwing. It is true this species does not altogether agree with the others in neuration and wing-contour, but unless a separate genus is erected it is probably best to place it in *Mathania*. It is possible that the name *leucothea* really covers two species; my material, however, is insufficient to settle this question. *leucothea*.

agasicles. **M. agasicles** Hew. (23b), from Bolivia and Peru, is above lemon-yellow with grey apex to the forewing, the underside of the hindwing and the apex of the forewing bear undulate grey-green lines, through the middle of the hindwing runs a distinct stripe (as in the Indian *Hebomoia*-species), the costal margin of the hindwing is somewhat darker, the greater part of the forewing beneath is impure yellow and the veins are distinctly visible.

gaujoni. **M. gaujoni** Pouj. (= *agasicles* Hew?), from western Ecuador (Loja), is as large as *esther*, similar in shape to *Dapt. idiotica*, but the shape of the forewing more falcate, hindwing somewhat lengthened at the distal margin. Upper surface light lemon-yellow, apex of the forewing light brown-green. Under surface of the forewing as above, but paler, apex marbled with white-yellow. Under surface of the hindwing olive-coloured, anteriorly much darkened and marbled like the apex of the forewing; it has a transverse, yellowish olive longitudinal line. Between the three median veins are strongly darkened oblique lines, which give the hindwing the appearance of a leaf. Only known to me from the description.

aureo-maculata. **M. aureomaculata** Dogn. (23d), from western Ecuador (Loja), is similar to *gaujoni*, but the hindwing is rounded at the anal angle. Upper surface light lemon-yellow, the apex of the forewing olive-brown, very similar to that of *gaujoni*. Under surface of the forewing uniform lemon-yellow, the apex as above, but almost the whole of the cell is occupied by an orange-yellow spot, which extends along the costal margin and sends out rays between the adjacent veins. Under surface of the hindwing yellow, finely powdered with olive-coloured atoms, more strongly so at the costal margin, and four yellowish submarginal dots. — A ♂ before me from North-East Peru (Huancabamba) answers to this description; another ♂ from Hillapani is above very light yellow, almost white, also beneath much more whitish, the orange-yellow spot in the cell of the forewing somewhat smaller and the yellow interneural stripes are narrower in the anterior part of the wing and altogether absent in the posterior part: **pallida** subsp. nov. (23d).

esther. **M. esther** Oberth. (= *aureomaculata* Dogn.?) (23b), from Bolivia, is deeper yellow than *agasicles*, particularly on the proximal part of the forewing, the apex of the forewing has even less grey marking. The under surface of the hindwing is grey-greenish, darker at the costal margin, through the middle of the hindwing from the base to beyond the cell extends an indistinct yellowish stripe; between the median veins are placed four yellowish submarginal dots. The anterior proximal part of the forewing beneath is orange-yellow, the rest light yellow.

17. Genus: **Hesperocharis** H.-Schäff.

This genus is distributed from Mexico to South Brazil. They are plain white or yellowish insects with mostly small markings on the upper surface and characteristically modified lunate markings beneath. Of the four subcostal veins only the first branches off proximally to the discocellulars, the second nearer to the apex, the third and fourth branches form a short fork in the apex. Both radials run free, but the upper discocellular is very small. The costal margin of the hindwing is somewhat flexuose, the precostal curved proximad. The *Hesperocharis* are lively little insects, which fly in the most burning sunshine (between 10 and 1 o'clock), and therefore scarcely deserve their generic name.

antipator. **H. antipator** Druce. Upper surface of both wings pure white, hindwing very long. Under surface of the forewing white, base, veins and apex spotted with yellowish scales; hindwing yellowish white with dark veins. Nearly allied to *leucania* Bdv., but differing from it by the elongated hindwing, whiter colouring and complete absence of markings on the underside. Vera Paz. — Only known to me from the description.

leucania. **H. leucania** Bdv. Shape as in *ilaire* (*drusilla*-♂), wings rounder. Upper surface without spots, greenish white as *Catopsilia florella* and *pyranthe*. Under surface of the forewing of the same colour, distal margin broadly yellowish. Under surface of the hindwing anteriorly greenish yellow, in the middle more grey, but little prominent oblique, curved, flexuose markings at the distal margin, interrupted by the veins. Brazil. — Only known to me from the description.

catasticta. **H. catasticta** spec. nov. (23e), from São Paulo, is superficially nearly allied to the *Catasticta*-species. Upper surface of the forewing pale sulphur-yellow, of the hindwing light ochre-yellow. The forewing has a rather broad black distal margin, in which small yellowish subapical spots are placed, and also a very irregular black spot on the discocellular and a black costal-marginal stripe, the hindwing has black triangular spots at the distal margin. Under surface of the hindwing yellowish white with black and yellow marginal spots, ground-colour of the hindwing white with black triangular distal-marginal spots, a submarginal lunate band of the same colour, a large indistinct black spot near the inner margin; in all the cellules there are placed yellow spots, at the base a red spot.

nera. **H. nera** Hew. (23e), from Ecuador and Bolivia, is above white, at the base of the hindwing yellowish and at the apex of the forewing grey-black. Under surface of the forewing white, apex paler grey than above and yellowish, ground-colour of the hindwing white with diffuse grey-blackish marginal, submarginal and median spots, as well as yellow streaks in the cellules of the hindwing and orange-yellow *boliviana* basal spot. — The somewhat smaller **boliviana** form. nov., from Bolivia, which has very weak markings

beneath, appears to be a seasonal form. — **nereis** *Fldr.* (23f), from Colombia, has the apical marking of *nereis*. the forewing above broken up into stripes and the under surface of the hindwing somewhat lighter. — **amazonica** *Fruhst.*, from the Upper Amazon, has broader black apical marking on the forewing and rather *amazonica*. broad black distal margin on the hindwing. The under surface is white with grey-black markings and sharp orange-yellow basal spot. — **flavescens** *form. nov.* (23e) (aberration or seasonal form?) differs from it beneath *flavescens*. by a large light yellow spot in every cellule of the hindwing and yellowish stripes at the proximal part of the dark apex of the forewing. — **nilios** *Fruhst.*, from the Rio Waupes, has a broader, dentate distal margin of *nilios*. the hindwing and also darker and broader markings on the hindwing beneath, by which it is distinguished from the less marked **nymphaea** *Möschl.*, from Surinam. — **flaveola** *Fruhst.*, from Ecuador, is above and *nymphaea*. beneath a beautiful dark yellow, apex of the forewing beneath with obsolescent yellowish spots. — **aphaia** *flaveola*. *Fruhst.*, from the Rio Waupes, is a form of *nilios* with the upperside of the hindwing light yellow. — **aida** *aphaia*. *Fruhst.*, from Peru, is smaller than the preceding forms and has the upper surface of the hindwing yellow. *aida*. — Among it occurs **minia** *Fruhst.*, from Southern Peru, probably as a dry-seasonal form. Upper surface *minia*. white, hindwing without black distal margin. — **nirvana** *Fruhst.*, from Bolivia, has the upper surface pure *nirvana*. white with only moderately broad black apical spot, under surface almost pure white with completely diffuse black markings, only the apex of the forewing broadly suffused with light grey and a few remnants of black spots at the costal and distal margins of the hindwing, where also a few traces of the interneural stripes are preserved. To it belongs as a rainy-seasonal form **vitha** *Fruhst.*, similar to *amazonica*, but the hindwing *vitha*. with narrower black distal margin, otherwise entirely white, slightly suffused with ochre-colour at the base. Beneath at the apex of the forewing broadly grey-black with large whitish pointed spots, under surface of the hindwing with thick grey-black reticular marking and the apex of the cell broadly margined with grey; without orange-coloured interneural stripes.

H. costaricensis *Bates* (23f), from Costa Rica and Chiriqui, is above white with very slight dark *costaricensis*. markings at the apex of the forewing. Under surface of the hindwing and of the apex of the forewing dingy light yellow with indistinct dark markings, veins slightly dark, posterior part of the forewing white.

H. nereïna *Hopff.* (23f), from Peru and Bolivia, is above yellowish white with blackish markings in *nereïna*. the apex of the forewing and light yellow interneural stripes. The under surface of the forewing has yellow apex with dark markings and much more distinct yellow stripes; the latter are still more conspicuous on the hindwing and the hindwing has also blackish distal-marginal spots, a submarginal lunate line and black veins. — **elea** *Fruhst.*, from Bolivia and Peru, has dark yellow ground-colour above and beneath. — **phainia** *elea*. *Fruhst.*, from Peru, is a variety of *nereïna* with white upper surface and delicate orange-coloured interneural *phainia*. stripes beneath, — In **chloris** *form. nov.*, from Bolivia (Coroico), the upper surface is delicately greenish *chloris*. yellow-white and the black apical marking of the forewing is broken up into separate small spots. The under surface is purer white and the dark and yellow markings less sharp:

H. anguitia *Godt.* (23f), from South Brazil (Rio de Janeiro, São Paulo, Santa Catharina, Rio Grande *anguitia*. do Sul), is above white, sometimes (especially in the ♀) yellowish white and very little or scarcely at all marked with black at the apex and the distal margin of the forewing. The under surface of the hindwing and of the apex of the forewing is yellowish, the rest of the forewing white, on the hindwing and at the apex of the forewing blackish hook-shaped markings. Both the colouring and the markings of the under surface are somewhat variable. The ♀♀ have rounder wings and mostly even less markings. Seasonal forms appear to occur, which, however, differ very little.

H. catogramma *Koll.*, from Colombia, is allied to *anguitia*, larger; hindwing obtusely dentate, upper- *catogramma*. side white with a slightly yellowish tinge, distal margin and apex spotted with black; hindwing without spots. Under surface with pale saffron-yellow scaling on the forewing as above, only the spots are here changed to fine streaks, veins of the hindwing black, a zigzag line parallel to the distal margin. — Only known to me from the description.

H. erota *Luc.* (23e) occurs in the same localities as *anguitia*. It is somewhat larger, with more mark- *erota*. ings and has as characteristic mark a short, broad black streak, directed basad, on the under surface of the hindwing at the lower discocellular.

H. marchalii differs from the preceding species by its somewhat elongated and dentate hindwing; the distal margin of the forewing is also not smooth as in the other species. — **marchalii** *Guér.* (23f), from *marchalii*. Colombia and Venezuela, is above slightly yellowish white with small, pointed marginal and submarginal black spots on the forewing and a black distal-marginal line on the hindwing, which is somewhat thickened at the ends of the veins. The under surface is marked quite similarly to the preceding species, but the black streak at the lower discocellular is absent. — **coloë** *Fruhst.*, from Peru and Bolivia, has the under surface *coloë*. pale sulphur-yellow and the hindwing more deeply dentate. — **sulphurescens** *form. nov.*, from West Colom- *sulphu-* *rescens*. bia (Cauca Valley), has the upperside light sulphur-yellow and the underside somewhat deeper yellow. — **masonia** *Fruhst.*, from Ecuador, has dark sulphur-yellow upper surface and “more pointed” (more elongated *masonia*. posteriorly?) hindwing. Flies in April and again in October.

18. Genus: **Leucidia** *Dbl.*

This genus contains the smallest forms of Pierids and is confined to tropical America, for the statement that one species (*impura* *Voll.*) also occurs on Timor in the Indian Ocean is undoubtedly incorrect. The Leucidias have an extremely weak flight, for they fly so slowly that they can be caught with the hand in the air. The cause of this want of swiftness in flight lies probably (apart from the weakness of the body) in the form of the wings: the forewing is so very much rounded that it can hardly be said to have an apical angle. In structure this genus is more nearly allied with the superficially similar *Pontia* from India and Africa. The antennae are scaled along the whole length and gradually thickened to a small club. The subcostal is four-branched, the first branch arising far before the end of the cell and the second soon after it, the third and fourth branches form a short fork. The upper radial anastomoses to the half with the subcostal, consequently the upper discocellular is wanting. The hindwing has an almost straight costal margin, only very weakly emarginate, the simple precostal is curved proximally and the subcostal and upper radial have a common stalk. It is doubtful whether the forms erected as separate species are really independent or only forms of one or two species.

brephos. **L. brephos** *Hbn.* (= *leucoma* *Bates?*) (24f), occurring from Venezuela to South Brazil (São Paulo), is white with a very slight yellowish tone, sometimes there is a fine blackish line at the anterior part of the forewing. The under surface is white.

pygmaea. **L. pygmaea** *Frittw.* (24f), from Brazil (Rio de Janeiro, São Paulo, etc.), is above and beneath yellowish white with narrow blackish distal margin on the upperside of the forewing.

exigua. **L. exigua** *Frittw.* (24f), from Venezuela and the Brazilian province of Rio de Janeiro (Corcovado and Leopoldina) is larger, yellow, and has a considerably broader black distal margin on the forewing, which extends to the inner angle.

elvina. **L. elvina** *Godt.* (= *impura* *Voll.*) (24f), from Brazil (e. g. São Paulo), has slightly yellowish white upper surface and more strongly yellowish under surface; with rather broad black distal margin of the forewing above. My specimens of this species completely agree with the description and figures of *impura*, said to be indigenous to Timor.

19. Genus: **Terias** *Swains.*

This genus, which in the eastern hemisphere only extends a little beyond the tropics, occurs in America much further north, a few species advancing as far as the southern boundary of Canada. Though the *Terias* are mostly only small species, their richness both in species and individuals makes them quite a feature of the fauna. Their agility varies considerably; whilst the species with the apex of the forewing pointed (e. g. *gundlachia*) are good fliers, the round-winged species (e. g. *albula*) scarcely surpass *Leucidia*. With this genus begins the series of those Pierids which E. SCHATZ includes under the general name of "Dryads"; these are Pierids with the antennae short, strong, mostly without clubs, only gradually thickened towards the end and but rarely having a distinctly formed club. The species of *Terias* are mostly small, only exceptionally medium-sized, yellow or orange-coloured butterflies. The head is retracted; the eyes are naked and very little prominent, the palpi moderately long and laterally compressed, with large basal joint and small pointed terminal joint. The antennae are delicate, with gradually thickened, more or less distinct club. The subcostal is four-branched, with two branches before the end of the cell, the upper radial is partly coincident with the subcostal, consequently the upper discocellular is wanting. The hindwing is rounded or bears a short tail. On the position of the upper radial of the hindwing BUTLER has based the genera *Sphaenogona* (with *ectrica* *Dbl.* as type) and *Pyrisitia* (with *proterpia* *F.* as type). The origin of this vein is however rather variable: it either arises from the cell or at the origin of the subcostal or it has a common stalk with the latter. But as all sorts of transitions occur between these positions, the position of the upper radial is of no use as a generic character. — The larvae are slender, with short, soft hairs and mostly green. The pupae are somewhat curved, weakly compressed laterally, keeled on the dorsum, without lateral spines and narrowed to a point anteriorly. — The species of *Terias* prefer open situations with low shrubs and moist places, on which they often appear in large numbers, sometimes they congregate in great crowds, which often traverse long distances, even over the sea. They probably occur without exception in at least two generations, which are sometimes very different superficially, but the identity of the seasonal forms has only been proved in very few exotic species. Doubtless they have likewise developed local forms, but concerning this also very little is known with certainty. — A large number of *Terias*-species have been erected which very probably might be united with those dealt with below. In many cases mere individuals, and often also scarcely tenable local forms have been described as separate species. We cannot here go into the classification of all these unimportant forms, that would rather be a task for a monographic work on the genus. For the large African Region CHR. AURIVILLIUS only accepts eight species (including two doubtful ones). As in the following pages 43 species in 86 forms are dealt with, no principal form at any rate will be left unnoticed.

T. gundlachia *Poey* (24a), from Cuba, Mexico, Texas and Arizona, has the forewing rather sharply pointed and the hindwing prolonged into a tail. Upper surface orange-yellow with sharp, broad costal margin and narrower and less sharp distal margin on the forewing. Under surface paler orange-yellow, on the hindwing with brownish spots and reddish yellow dusting.

T. longicauda *Bates* (24a), from California, has the hindwing more pointed. The upper surface is lighter orange-yellow and the black margin of the forewing is essentially different in form from that of *gundlachia*. The ground-colour of the under surface is somewhat lighter, but the marking does not differ from that of *gundlachia*.

T. proterpia *F.* (24a), from the Antilles and the north of South America (Mexico to Venezuela), has the hindwing weakly angled and the forewing less pointed than in the preceding species. Upper surface somewhat darker orange-yellow than *gundlachia*, in the ♀ more yellowish and the black apical markings somewhat broader. Under surface of the forewing light orange-yellow, of the hindwing yellow with small and indistinct macular marking.

T. nicippe *Cr.* (24a) occurs from New England to the northern part of Brazil and on the Antilles. Ground-colour of the upper surface quite similar to that of *proterpia*, but *nicippe* is distinguished by the broad dark margins. The ♀ has paler ground-colour, sometimes yellow specimens occur: ab. **flava** *Holl.*; *flava*. The under surface is yellow, slightly sprinkled with brownish, on the hindwing with larger red-brown spots. Little is known of the first stages; the larva lives on *Cassia* and other Leguminosae.

T. mexicana *Bdr.* (= *boisduvaliana* *Fldr.*) (24a), from Mexico, Arizona and Texas, is white above, sulphur-yellow on the anterior part of the hindwing, and has very broad, deeply sinuate black margins. The underside of the forewing is white with yellow margin, that of the hindwing sulphur-yellow with brownish markings in the centre and at the costal margin. — In **bogotana** *Fldr.*, from Colombia, the yellow colouring on the anterior part of the hindwing is wanting.

T. gratiosa *Dbl. & Hor.* (24b), from Venezuela (known to me from Honduras), has the upper surface of the forewing sulphur-yellow, the hindwing white, and at the costal angle a large light orange-yellow spot and broad black-brown margins. The under surface is uniformly yellow with a small black spot at the discocellular and slight, indistinct brownish markings at the distal margin. — **ingrata** *Fldr.* (= *gratiosa* *Reuk.*), from Mexico and Central America, has yellow upperside of the hindwing and still broader dark margins.

T. arbela *Hbn.* (24b), from South Brazil, is above dark sulphur-yellow with rather broad black margin on the forewing and narrower margin on the hindwing; the latter varies somewhat, and is entirely wanting in the ♀, which has also paler ground-colour. Under surface yellow with more or less developed red-brown marginal and central markings. — **gaugamela** *Fldr.*, from Colombia and Mexico, has deeper yellow ground-colour, broader and darker distal margin to the forewing and beneath more, but smaller red-brown spots. — **boliviensis** *Stgr. i. l.*, from Bolivia, has a large light orange-yellow spot at the apex of the hindwing and broader dentate distal margin of the latter; the ♀ is paler and has more markings. — **fabiola** *Fldr.*, from Venezuela, has narrow black margins and the hindwing above is light orange-yellow and less pointed. — **chloë** *Fldr.*, from Colombia, has broader black margin to the forewing, the hindwing sharply pointed but less suffused with orange-yellow. — **damaris** *Fldr.* (= *mexicana* *Bdr.*, *damarina* *Stgr.*), from Mexico and Arizona, has deep yellow forewing and light orange-yellow hindwing, with sharply defined black distal margin on the hindwing. Under surface of the hindwing straw-yellow with large and small brownish spots. — **pomponia** *Hopff.*, from Peru, is large, brilliant yellow, with strongly dentate black distal margin on the forewing and very narrow distal margin on the hindwing. — **salome** *Fldr.*, from Ecuador, is very similar to *pomponia*, but smaller, and with the hindwing more strongly suffused with orange-yellow. — **limoneus** *Fldr.*, from Venezuela, is differentiated by longer wings, more acutely angled hindwing, lighter colour on the upperside, broader, more deeply incised distal margin of the forewing and narrower, shorter bordering of the hindwing. — **theodes** *Fldr.*, from Venezuela, is probably only the ♀ of *constantia*. — Also **theona** *Fldr.*, described from a ♀, appears to be only a somewhat aberrant female specimen.

T. ectriva *Bth.* Above very similar to *salome*, but the wings longer; forewing with broader dark brown distal margin, its irregularities less pronounced, angle of the hindwing less produced. Under surface similar to that of *constantia*. Ecuador (Archidona). — Is the type of BUTLER's genus *Sphaenogona*. Only known to me from the description.

T. sybaris *Hopff.*, from Peru (Chanchamayo), is very large, in the female sulphur-yellow, with broad black distal margin on the forewing, which has proximally four excisions. Hindwing angled, at the costal margin whitish, at the apex spotted with black. Forewing beneath with a black stripe at the costal margin, apex reddish. Hindwing marbled with red-brown, at the apex a large red-brown patch of scales and extending from the cell a reddish stripe.

T. xanthochlora *Koll.* (24b), from Colombia and Chiriqui, has the hindwing only feebly angled. Upper surface sulphur-yellow with black-brown distal margin on the forewing, on the hindwing in many

cases a black distal-marginal line. ♀ much paler. Under surface uniformly yellow with slight brownish markings on the hindwing. — **constantia** *Fldr.*, from Venezuela, is paler yellow in both sexes and has somewhat reduced black distal margin to the forewing. The under surface of the hindwing has larger and more reddish spots and the apex of the forewing margined with dark rose-red.

T. graduata *Btlr.* Forewing above saffron-yellow, base blackish, distal margin rather broadly and irregularly black, more than in *constantia*, but the irregularities less pronounced; hindwing on the abdominal half white, apical half saffron-yellow, at the apex gold-yellow: distal margin with distinct black border. Peru. — Only known to me from the description.

T. westwoodi *Bdr.* (24b), from Mexico, Costa Rica, Texas and Arizona, is above lemon-yellow, with orange-yellow tinge at the distal margin of the hindwing, or else entirely orange-yellow. The dark brown, dentate margin of the forewing is moderately broad, the border of the hindwing very narrow or only indicated. The under surface is yellow with slight orange-yellow tinge at the distal margin and two black dots at the discocellular of the hindwing; sometimes the hindwing shows slight, indistinct orange-yellow markings. — **citrina** *Poey.*, from Cuba, is a small form with strongly orange-yellow colour at the distal margin of the hindwing.

T. reticulata *Btlr.* (24b), from Peru, is a conspicuous species, one of the largest of the genus. The upper surface is canary-yellow with black-brown apex to the forewing and small black dots at the distal margin of the hindwing at the extremities of the veins. The under surface of the forewing is somewhat paler than the upper, at the costal and distal margins somewhat darker, and with a black spot on the discocellular. The hindwing has dark yellow ground-colour and thick red-brown reticulate marking, also some large spots of the same colour. — **marmorata** *Pouj.*, from Ecuador, has beneath less distinct reticulate markings.

T. doris *Stgr. i. l.* (24b), from Bolivia, is perhaps only a gigantic form of the following species. It is vivid yellow above with broad black-brown apical markings. The under surface is likewise vivid yellow, with red apical margin on the forewing and some large red-brown spots on the hindwing.

T. deva *Dbl.* (24c), from South Brazil, Uruguay and Argentina, is above paler yellow than the preceding species and has narrower apical marking. The less vivid yellow upper surface has on the hindwing much more red-brown macular marking, — **chilensis** *Blanch.*, from Chile, is smaller than *deva* and the apical spot is straight on the proximal side. It flies in two broods: in November and again February to April. The larva lives on Cassia. — **hahneli** *Stgr.*, from the Upper Amazon, is somewhat larger than *deva* and the black marginal marking of the forewing extends almost to the inner angle.

T. leuce *Bdr.* (24c), from South Brazil and Uruguay, differs from *deva* by the narrower but longer apical and distal-marginal marking of the forewing and the fuller yellow ground-colour. The under surface has no red-brown markings on the hindwing, but sometimes slight blackish ones.

T. dina *Bdr.* Upper surface beautiful chrome-yellow, orange at the margin of the hindwing. The forewing has a straight black distal margin, which extends to the inner angle and the costal margin. The hindwing has the black distal margin before the fringes more than usually narrow. Under surface of the forewing of a beautiful yellow with a small black median spot, under surface of the hindwing uniformly yellow with a blackish dot near the base, two small blackish median spots, then an oblique row of irregular brownish spots of scales. ♀ somewhat larger, with broader margin. Cuba, common. — **athalia** *Fldr.*, from Colombia, is larger, costal margin of the hindwing more convex.

T. calceolaria *Btlr. & Druce.* ♂ above deeper yellow than *dina*, black distal margin almost obsolete. in the ♀ the black apical area almost as in *deva*, triangular, hindwing with a golden yellow apical spot. Honduras.

T. hecabeoides *Mén.* (24c), from Haiti, is so like the extraordinarily variable Indian *hecabe* *L.* that according to MÉNÉTRIE's figure scarcely any distinguishing characters can be found. Upper surface yellow with broad, deeply sinuate distal margin of the forewing and narrow black margin of the hindwing. Under surface yellow with blackish markings.

T. aesiope *Mén.* (24) has the forewing marked quite similarly to that of the preceding species, but the hindwing instead of the black distal margin has only black dots at the extremities of the veins. The yellow under surface shows irregular red-brown spots. — Haiti.

T. jaegeri *Mén.* (24c), from Haiti, is very similar to the Indian and Japanese *laeta* *Bdr.* Upper surface yellow with broad black apical and distal-marginal border, sharply cut off at the first median, under surface grey with darker markings, proximal part of the forewing yellow.

T. thymetus *F.* (= *perimede* *Prittw.*) (24c, d), from South Brazil (also recorded from Haiti), is above very similar to *leuce*, only somewhat lighter yellow, and has at the distal margin of the hindwing brownish spots, but is sharply distinguished by the style of marking of the underside. This is yellow with slight blackish markings in the middle of the hindwing and a large brownish spot at the apex of the forewing and at the distal margin of the hindwing.

T. stygma Bdr. (24d). Size and shape of *brigitta*. Upper surface lemon-yellow, the forewing with a broad triangular black spot, which is somewhat produced at the costal margin and reaches to the inner angle. Under surface of the forewing yellow, with the band as above, but light rust-brown and slightly reddish. Under surface of the hindwing ochre-yellow, with two brown dots at the anterior margin of the cell, followed by a row of brown, interrupted zigzag markings, a large rust-brown spot at the outer angle as in *lisa*, but larger. Peru. — **stygmula** Bdr., from Cuba, is very similar, but has smaller spots on the underside. — **nisella** Fldr., from South Brazil (Rio), is based on a single female specimen whose principal difference appears to be the sulphur-yellow colouring of the upper surface. Only known to me from the description.

T. neda Godt. (24d), from Guiana, Venezuela and Nicaragua, is vivid lemon-yellow with black-brown apical area to the forewing; at the distal margin of the hindwing are placed black dots. Under surface yellow with very slight blackish markings on the hindwing. — **tenella** Bdr., from Brazil (Bahia, Santa Catharina, São Paulo), is above lighter yellow and has continuous narrow black distal margin on the hindwing. Also the underside is lighter yellow. — **circumcincta** Bates, from the Amazons, **venustula** Stgr., from Chiriqui, and **nelphe** Fldr., from Mexico, as well as several other forms, differ so little that reliable characteristics cannot be adduced.

T. nise Cr. (24d), from Surinam and Dominica, is also very similar to *neda*, but has narrower black distal margin on both wings and extraordinarily light hindwing. The under surface is lighter yellow, the markings not different.

T. venusta Bdr. Similar to *nise*, but smaller, the margin of the forewing proximally less dentate, border of the hindwing reduced to some black marginal dots. Under surface light yellowish on both wings and in both sexes, in the middle of the hindwing one or two small blackish dots as in *nise* and *tenella*, and a row of distinct, oblique brownish spots. Jamaica, Colombia.

T. musa F. (= *gentilis* Bdr.). The same size as *venusta*, upper surface white, forewing with a broad black marginal band, slightly sinuate proximally, base dusted with grey. Hindwing with beautiful lemon-yellow margin, separated from the fringes, the latter white with small black spots. Under surface whitish, slightly yellow distally, base of the forewing lemon-yellow, in the middle of the hindwing two very small black dots. South America.

T. limbia Fldr. (24d), from Venezuela, has vivid canary-yellow forewing and almost white hindwing, somewhat more strongly sulphur-yellow at the distal margin. The black-brown distal border of the forewing is rather broad, proximally dentate, the black distal border of the hindwing narrow. The under surface of the forewing is yellow, without markings, the under surface of the hindwing very light yellow, at the margins somewhat deeper yellow, with two black dots on the discocellulars. The ♀ has the upperside pale sulphur-yellow, no dark distal margin to the hindwing, the underside yellower, with blackish macular marking on the hindwing.

T. lisa Bdr. & Lec. (= *smilax* Godt.) (24d) occurs from New England to Honduras and has also been found on the Antilles and Bermudas. The upper surface is vivid yellow with rather broad black-brown margins and a black dot at the discocellular of the forewing. The under surface is somewhat lighter yellow with reddish distal margin, a large reddish spot at the apex of the hindwing, two small black dots on the discocellulars of the hindwing, a similar one on those of the forewing and indistinct blackish spots on the hindwing. The ♀ is paler yellow and has broader dark margins, which on the posterior part of the hindwing are broken up into spots, the under surface is darker yellow and somewhat more marked than in the ♂. Although this species is very common in places (cnf. the note on migration in the Introduction) the earlier stages are still very insufficiently known. Larva green with two whitish stripes at each side, head yellowish. Pupa dark green, slender, breast prominent. The larva lives on Cassia and clover. — **euterpe** Men., from Nicaragua, has broader black distal margin on both wings.

T. delia Cr. (= *demoditas* Hbn., *daira* Godt.) (24d), from the Gulf States of North America, is above yellow with broad black apical marking and a broad black inner-marginal stripe on the forewing, as well as a large black spot at the apex of the hindwing. The under surface is sand-brown with the exception of the yellow proximal part of the forewing, the hindwing has slight dark macular markings. — **lydia** Fldr., from Venezuela, has shorter, broader wings, the apex of the forewing more obtuse and the distal margin less arched, broader hindmargin, proximally more deeply convex, and considerably narrower proximal band on the forewing, the distal margin of the hindwing almost twice as broad.

T. jucunda Bdr. & Lec. (= *ebriola* Pogy, *albina* Pogy) (24e), from the Gulf States of North America, differs from *delia* in the longer marginal band of the hindwing and the lighter, grey to white under surface, almost without markings. — **lemnica** Fldr., from Bahia, is distinguished not only by the broader border of the forewing, the larger apical spot of the hindwing which is joined to the other marginal spots, and the quite different under surface, which is glossy white, sparsely dusted with red-brown, but also in the greater length of both wings.

- persistens.* **T. persistens** *Blth. & Druce*. Allied to *delia* and *eugenia*, upper surface yellow, costal margin and base broadly ash-grey, apex and distal margin broadly black-brown, a black-brown inner-marginal band distally bordered with gold-yellow; hindwing with black-brown apical spot, under surface as in *delia*. Honduras.
- hyona.* **T. hyona** *Mén.* (24e), from San Domingo, is beautiful orange-yellow in the male above with black margin, which is moderately broad on the forewing, narrow and sharply defined proximally on the hindwing. The ♀ has much paler upper surface. Beneath both sexes are almost alike; forewing in the middle orange-yellow, at the distal margin and in the basal part yellow, with a subapical row of small black spots, fringes reddish; hindwing yellow with some blackish dots near the base, some small red-brown spots at the apex, to which extends a narrow band of red-brown spots running towards the inner margin, and small, very indistinct red-brown submarginal spots.
- pyro.* **T. pyro** *Godt.* Shape and size as *hyona*. Upperside of the forewing vivid orange-yellow, slightly blackish at the base. Forewing with a black margin, proximally indented. Hindwing at the distal margin slightly dusted with blackish. Under surface of the forewing lighter than above, with a black dot in the middle and a dark apical spot. Under surface of the hindwing light yellow, with an orange-yellow central spot, some brownish scales and a very large round rust-brown spot at the apex, and also a row of small black marginal dots. Antilles or South America.
- eleathea.* **T. eleathea** *Cr.*, from Surinam, is not essentially different from **plataea** *Fldr.* (24e), from South *plataea.* Brazil (São Paulo, Santa Catharina, Rio Grande do Sul). The latter has yellow forewing and white hindwing, broad margin on the forewing and narrower one on the hindwing, also a black stripe at the inner margin of the forewing, which is posteriorly edged with orange-yellow. The under surface is rather variable, whitish to grey, the anterior part of the forewing yellow, mostly only with black dots at the discocellular of both wings, not seldom with somewhat darker markings. The ♀ has yellow or yellowish ground-colour on the hindwing above, the black and orange-yellow stripe at the inner margin of the forewing is absent. The under surface is mostly darker and more abundantly marked. This species also shows a number of *vitellina.* local forms, which have almost all been described as separate species, thus **vitellina** *Fldr.*, from Venezuela and Honduras, with white-scaled inner-marginal stripe and the under surface entirely without markings; — *eugenia.* **eugenia** *Wall.* (= *rhodia* *Fldr.*), from Venezuela, Colombia and St. Josef, with very dark yellow forewing *cubana.* and sharp and broader orange-yellow inner-marginal stripe; — **cubana** *H.-Schäff.*, from Cuba, with broad *palmyra.* black distal margin on the hindwing; — **palmyra** *Pocoy* (= *lydia* *Fldr.*), from Cuba and the Gulf States, in *phoenicia.* which the black distal margin of the hindwing is reduced to a spot at the apex; — **phoenicia** *Fldr.*, from Colombia and Ecuador, has orange-yellow inner-marginal stripe reaching to the base and rather broad distal *elathides.* margin on the hindwing; **elathides** *Stgr.*, from Venezuela, is larger, and has no orange-yellow inner-marginal stripe; the ♀ is darker beneath. — All these forms can scarcely be separated from one another. Considerably *sidonia.* different on the other hand are: **sidonia** *Fldr.*, from Mexico, in which the black inner-marginal stripe is merged together with the black distal margin and the hindwing has very broad black distal margin; — *ella.* **ella** *form. nov.*, from Ecuador, has no orange-yellow inner-marginal stripe, also the black inner-marginal stripe is merged together with the black distal margin and the hindwing has a broad black distal margin *tegea.* which is sharply defined proximally. — **tegea** *Fldr.*, from Colombia, is larger than *vitellina*, with broader wings, and may be recognised by the greater width of the inner-marginal band of the forewing and the *medutina.* distal-marginal one of the hindwing. — **medutina** *Fldr.*, from Venezuela, has narrower wings, the forewing is more elongated and the hindwing shorter.
- priddy.* **T. priddy** *Lathy*, from Haiti, differs from *eleathea* in the yellow upper surface of the hindwing, the shorter dark distal-marginal band of the forewing and the absence of the yellow stripe at the inner margin of the forewing and of the dark distal margin of the hindwing, which is only represented by marginal spots.
- mycale.* **T. mycale** *Fldr.* (24e), from Brazil (Bahia, São Paulo), is very similar to *eleathea*. The dark distal margin of the forewing is broader and confluent with the hindmarginal stripe, also the distal margin of the hindwing is much broader. The under surface of the forewing is less yellow, otherwise not different.
- smilacina.* **T. smilacina** *Fldr.*, from Colombia, was described from a ♀. Upperside pale sulphur-yellow with black-brown distal margin, hindwing with black marginal dots. Underside glossy white, at the discocellular a crescent-shaped spot, a subapical red-brown macular band, a black dot at the costal margin near the apex of the forewing; hindwing with spots at the discocellular, a subapical macular band and black marginal dots.
- albula.* **T. albula** *Cr.*, from Surinam, probably scarcely differs essentially from **marginella** *Fldr.* (24e), from *marginella.* Venezuela. This is white above and has moderately broad black margin on both wings. The under surface is white, entirely without markings. — *sinoë.* **sinoë** *Godt.* (= *cassiae* *Sepp.*, nise *Hbn.*), from South Brazil, has more or less broad distal margin on the forewing and entirely white wings. The under surface is white or sometimes yellowish. The ♀ has narrower and shorter distal margin on the forewing and some dark markings on the hindwing beneath.
- deflorata.* **T. deflorata** *Koll.*, from Colombia, is similar to *albula*. Upper surface white, forewing with a yellowish tinge, apex black, irregularly defined proximally, at the distal margin of the hindwing three to four blackish

streaks. Under surface of the forewing at the base lemon-yellow, at the apex slightly dusted with red-brownish. The hindwing has a scarcely perceptible yellow tinge and before the distal margin a stripe composed of brownish atoms, which, however, is not at all conspicuous. Only known to me from the description.

T. agave Cr. (= *jodutta* Hbn., *phiale* Godt., *mana* Bdr.) (24f), from Surinam, has the forewing much *agave*, rounded and very narrow. Upper surface white with black markings at the apex and blackish dusting at the base of the forewing. Under surface white on the proximal part of both wings, otherwise yellow, with a black dot at the discocellular of the hindwing and slight blackish markings on the hindwing.

T. messalina F. Shape and size as *rahel*. Upper surface white, distal margin of the forewing and *messalina* a marginal spot on the hindwing black. Under surface yellow, with a brown spot at the apex of the forewing, a marginal spot and black scales on the hindwing. — Jamaica.

T. gnathene Bdr. Shape and size of *albula*. Upper surface white with a very slight greenish tinge, *gnathene*, black distal margin, which is rather strongly widened at the apex and terminates in the anal angle of the hindwing. Under surface of the forewing white, at the base and apex lemon-yellow, a longitudinal row of reddish spots at the inner margin, a blackish spot at the apex, a violet subapical spot. Under surface of the hindwing yellowish, with a small, light rust-brown lunular spot at the margin of the cell, a deep rust-brown and a deep red-brown spot (less sharply defined) at its posterior margin. — Yucatan and Cuba.

T. phiale Cr. (24f), from the eastern part of tropical South America, is white with black margin to *phiale*, the forewing and narrow black distal margin to the hindwing, before which is placed a light yellow band. The under surface is light yellow and almost without markings except for two black dots at the discocellular of the hindwing. — **columbia** Fldr. (= *phialina* Stgr. i. l.), from Colombia and Bolivia, has somewhat *columbia*, narrower distal margin on the forewing, proximally almost rectilinear, and the black distal margin of the hindwing less developed. — Whether **paula** *form. nov.*, from São Paulo, is a separate species or a form *paula*, (perhaps a seasonal form) of *phiale*, I cannot say from the two male specimens before me. The black distal margin of the forewing only reaches to the first median vein, that of the hindwing is broken up into small dots and the under surface of the hindwing is dark yellow. Has two conspicuous black dots at the discocellular and copious grey-brown macular marking. The apex of the forewing is likewise dark yellow.

20. Genus: **Catopsilia** Hbn.

This genus has about the same range as *Terias*. In the mountains no species appears to ascend beyond 2000 m. The species which belong here are mostly of considerable size and fine, sometimes conspicuous, colouring. The powerfully built body and the shape of the wings make the insects particularly adapted for swift flight. They use this capacity for distant migrations, in which extraordinarily large crowds sometimes participate, their passage often lasting for hours. Apart from this the common species occur in large swarms, enliven the damp banks of the rivers and contribute materially to the character of the fauna of their district. The *Catopsilia*-♂♂ are not only immoderate water-drinkers, but are also attracted by human sweat and urine, as Dr. FR. OHAUS proved during his travels in South America. He also observed swarms of *Catopsilia* on the stranded bodies of fishes. The ♀♀ mostly remain in the woods and visit flowers, on which of course ♂♂ are also to be met with when they seek the company of the ♀♀. — The rather large head has prominent naked eyes, the palpi only project a little beyond the head, the antennae are short and moderately soft, without distinct club, with truncate or indented tip. Subcostal four-branched, the first branch beyond half way between the base and the discocellular, the second branch arising shortly before the discocellular, the fourth branch running into the distal margin, the upper radial coincident with the subcostal to $\frac{1}{4}$, the middle discocellular shorter than the proximally curved lower one. Hindwing rounded, in some species prolonged into a tail at the submedian. The precostal is a mere knob. The larvae have the usual Pierid shape and granulated skin, are grey or green and have a light lateral longitudinal stripe; they live on Cassia. The pupae are rather variously shaped; as far as they are known they will be described under the respective species. — Contrary to the usual custom I refer (with A. G. BUTLER) *menippe* to the following genus, from which it only differs in neuration by an unimportant deviation, whilst in its other characters *menippe* agrees with *Gonepteryx*. — This genus contains some species which in beauty must be considered as the climax of development among the Pierids.

C. eubule L. (= *marcellina* Cr.) (25a) occurs from New England to Argentina, also on the Antilles. *eubule*. Upper surface in the ♂ lemon-yellow, lighter at the distal margins, and with black marginal line. Beneath somewhat paler yellow with a silvery "eight", edged with red-brown, on each wing at the discocellular, a black marginal line and irregular dark markings on both wings. The ♀ is somewhat paler yellow, has a row of marginal spots on both wings, a large black median spot on the forewing and sometimes more or less dark brown marking. The under surface is deeper yellow and more marked than in the ♂. — **sennae** L. *sennae*. (= *yamana* Reak.) is beneath deeper yellow and more abundantly marked, the ♀ being pale orange-yellow

drya, above. — ***drya* F.** (= *amphitrite* Blanch.), from Peru, Chile, Cuba and Haiti, is a small, weakly marked form. — *ebule* flies in June and again from September to October, *drya* in November to December and from March to April. The ♂ has as scent-organ on the upper surface of the hindwing near the costal margin a spot of scales, over which the soft, widened inner margin of the forewing is stretched out to stir up the scent, scattering it with a pencil (retractile into a fold in the skin).

cipris. ***C. cipris* F.** (= *bracteolata* Bthr.) (25c), from Brazil and Peru, has the hindwing prolonged into a tail in both sexes. The is very light orange-yellow, the broad distal margin of the forewing, which is thickly covered with chalky scent-scales, and the considerably narrower distal margin of the hindwing lighter; the upper surface has no markings except small marginal spots on the forewing. The under surface is darker yellow with a silvery eight on both wings and more or less dark markings. The underside is very variable. The ♀ is lemon-yellow and has a large black median spot on the forewing, the under surface

neocypris. is more greenish than in the ♂. — ***neocypris* Hbn.**, from the same localities, is in both sexes suffused with orange-yellow above at the margins and is also darker beneath. Probably a seasonal form. — ***irrigata* Bthr.**, *virgo*. from Brazil, is an aberrant female form, more strongly marked above and beneath. — ***virgo* Bthr.**, from Central America, is more strongly marked, has black marginal spots in both sexes, also in the ♂ a large black median spot on the forewing, and the ♀ is white above with narrow red distal margin.

rudina. ***C. rudina* Fldr.** (25b), from Venezuela, Colombia, Ecuador and Peru, occurs apparently only at elevations of 1000 to 2000 m. The forewing in the ♂ is orange-yellow except for the distal margin of lemon-yellow scent-scales which occupies almost half the wing, the hindwing lemon-yellow with broad, light orange-yellow distal margin, at the distal margin of both wings are placed small black-brown spots. The under surface is yellow with a silvery double spot at the discocellular of each wing and more or less black-brown markings. The ♀ is very variable, from bright yellow to almost white ground-colour, stronger distal-marginal markings and a large black-brown median spot on the forewing and also large red distal-marginal spots or broad red distal margin on the hindwing. The under surface has paler ground-colour and more red-brown markings, often united into large spots. — ***intermedia* Bthr.** is the Central American form: the orange-yellow colour of the forewing of the ♂ is almost entirely absent and the ♀ has whitish ground-colour.

philea. ***C. philea* L.** (= *argante* Hbn., *corday* Hbn., *aricie* Cr., *melanippe* Cr., *lollia* et *aricia* Godt.) (25c), distributed from Texas to South Brazil, very common in some places, also observed in Illinois as a migrant, is one of the most beautiful species of this genus. The upper surface in the ♂ is a fine canary-yellow with a large orange-yellow median spot on the forewing and broad orange-yellow distal margin on the hindwing. The under surface is pale yellow with silvery median double spot and brownish markings. The secondary male characters consist of a spot of scent-scales on the upperside of the hindwing, to which corresponds a pencil found on the underside of the inner margin of the forewing, and a moderately broad band of scent-scales on the upperside of both wings, only slightly contrasting in colour. The ♀ is less brilliant yellow, the large orange-yellow median spot of the forewing is absent, but it has a large black-brown median spot and marginal, submarginal and costal macular markings on the forewing, as well as dark marginal spots on the hindwing. The ground-colour of the under surface is redder than in the ♂. — ***thalestris* Ill.** (= *huebneri* Fruhst.), from the Antilles, also reported from Chile (?), has in the ♂ a larger orange-yellow median spot, also a large black-brown spot at the discocellular of the forewing. The under surface is much more marked and shows at the distal margin of the hindwing large red-brown spots. The ♀ has much more red above and beneath and is much more strongly marked, especially on the under surface, which shows on the hindwing a broad red-brown distal margin and a large median spot of the same colour. — Pupa regularly canoe-shaped, dorsum strongly incurved, head prolonged into a long point.

avellaneda. ***C. avellaneda* H.-Sch.** (25d), from Cuba, is unquestionably the most beautiful species of the genus. In the ♂ the ground-colour of the upper surface of the forewing is canary-yellow, a broad margin ochre-yellow, the distal margin narrowly red, the central and posterior part of the wing is gorgeous carmine, at the discocellular is placed a red spot with black centre. The hindwing is less fiery carmine, in the cell yellowish red, the long spot of scent-scales placed at the subcostal is white, the distal margin rather broadly ochre-yellow. The under surface is red-yellow with white double spot in the centre of each wing and continuous black-brown submarginal spots. The ♀ has the upperside of the forewing canary-yellow with red distal margin and marginal and submarginal red-brown spots as well as a large red-brown spot at the discocellular, the basal part of the wing is sprinkled with red. The hindwing is yellowish red, at the costal margin light pink, with marginal and submarginal red-brown spots. The under surface has dark yellow ground-colour, the broad distal-marginal band is blue-red with red scales, the margin itself narrowly yellow; the broad blue-red distal margin is proximally bordered by black crescent-shaped spots and at these as well as at the base there is dark red colouring, at the discocellular of each wing are placed white, black-edged spots (five on the forewing, two on the hindwing). — ***solstitia* Bthr.** (25d), said to be from Chile, but probably an aberrant form of *avellaneda* and therefore also indigenous to Cuba, is differentiated from the latter by a narrower and proximally rectilinear ochre-yellow distal margin on the upper surface and by the

carmine spots of the forewing being reduced proximally. On the supposition that the locality "Chile" is correct, BUTLER regards *solstitia* as a separate species on account of a few small differences in the hairs of the body.

C. editha Btlr. (26a), from Haiti, is in the ♂ lemon-yellow without markings, the under surface *editha*. is dark yellow with two white spots, surrounded with black-brown, at the discocellular of the hindwing and also small black-brown macular markings. The ♀ has the upper surface reddish yellow, especially on the hindwing, with a large black median spot and marginal and submarginal black-brown spots on the forewing, and also small black-brown marginal spots on the hindwing, the under surface is scarcely different from that of the ♂. — **fornax** Btlr., from Chile (?), I regard as a ♀-form of *editha*. The upper surface has much more *fornax*. red, particularly a broad dark red marginal band on the hindwing, and the under surface, the proximal half of which is yellow, has many more red markings.

C. argante F. (= larra F., enidia Godt.) (25a) is distributed from the North American Gulf States *argante*. to Paraguay and very common. The ♂ is above pale orange-yellow and without markings except the black marginal spots. The rather narrow margin of scent-scales is little conspicuous, this species like several others has a further scent-organ, consisting of a spot of scales on the upperside of the hindwing, which is associated with a pencil on the underside of the inner margin of the forewing for scattering the scent. The under surface is yellow with numerous brownish markings and sometimes white spots at the discocellular. The ♀ has similar ground-colour on the upperside, but more black marginal markings, also a black median spot on the forewing. The under surface is more strongly marked with dark. The pupa has extraordinarily swollen breast, the head is produced into a point, on the thorax is an acutely angled elevation and along the sides runs a ridge-like protuberance. — **hersilia** Cr. is a more strongly marked form. The ♂ has in- *hersilia*. stead of the red marginal spots of the forewing a narrow black marginal band and the ♀ has more and larger black spots. The under surface is also more marked. — **rorata** Btlr., from Haiti, is a large form. *rorata*. The ♂ has unusually bright yellow marginal band and the ♀ with almost white ground-colour has much black macular marking as well as red striation on the upper surface. Also the under surface shows in the ♀ red-brown spots united into bands. — **minuscule** Btlr., said to be from Havanna, but which I have from *minuscule*. Rio Grande do Sul, is a dwarf form of *argante*, scarcely half as large. — **agarithe** Bdr., from Texas *agarithe*. (*argante*?), Panama, Venezuela, Haiti and Brazil, would have to be regarded as a separate species according to BUTLER's figure of the pupa. But BUTLER is in error; he has figured the pupa of *philea*, as I have positive proof. The butterfly is similar to *argante* in the ♂, but has a strongly marked light distal margin of unequal width on the hindwing and the posterior part of the wing is yellow. The under surface shows besides other markings on the forewing a red-brown macular band running from the apex towards the inner margin. The ♀ is above reddish yellow, with a large orange-yellow patch at the discocellular of the forewing, in which the black median spot is placed. The under surface is similar to that of the ♂, but more strongly marked. — **floridensis** Neumögen i. l., from Florida, is in the male entirely without markings above, *floridensis*. the margin little lighter than the proximal part of the wing, beneath on the contrary rather strongly marked, the band of red-brown spots running from the apex of the forewing towards the inner margin being particularly striking. The ♀ is above almost as uniform as the ♂, only somewhat lighter orange-yellow colour, and has no markings at all except slight brownish ones at and near the apex of the forewing and the very indistinct small dark median spot on this wing.

C. trite L. (25b), from tropical America, has yellow upper surface with black distal margin on the *trite*. forewing, which in the ♀ is somewhat broader. The margin of scent-scales is very narrow and inconspicuous, the scent-apparatus on the proximal part of the wing is as in the preceding species. The under surface is greenish yellow, lighter at the margin, and has besides slight submarginal markings on the hindwing an oblique blackish band, peculiar to this species, on both wings. The ♀ has lighter ground-colour beneath.

C. statira Cr. (26c) occurs very commonly in the whole of South America. The distal half of the *statira*. wing is covered with scent-scales and is strikingly lighter than the lemon-yellow proximal half. The upper-side has no markings except a narrow black distal margin. The ♀ has broader black distal margin and also a black median spot on the forewing. The under surface has slight dark markings. — **wallacei** Fldr., from *wallacei*. Rio Negro and Peru, is uniformly yellow above and has the distal half of the wing very light beneath.

C. boisduvalii Fldr. (26c), from Colombia and Central America, is cream-coloured, more strongly *boisduvalii*. yellow on the basal part, with narrow black apical margin. The under surface is light yellow, entirely without markings.

C. jada Btlr. (26b), from Guatemala, has in the ♂ the proximal half of the wings ochre-yellow, the *jada*. distal half lemon-yellow, no markings, the under surface is reddish yellow, lighter on the distal half. The ♀ is above yellow with black dentate distal margin and round black median spot as well as a subapical row of four small ochre-yellow spots. The under surface is bluish white with reddish marginal and medial markings. — **jaresia** Btlr., from Peru, is only known in the female. Like the *argante*-♀ it is orange-yellow *jaresia*.

with black median spot, but has on both wings continuous black marginal markings. The under surface is somewhat more reddish yellow than in *jada*, the markings almost the same.

godartiana. **C. godartiana** *Srauns.* (= *orbis* *Bdv.*) (26b), from Haiti and Porto Rico, has half the upper surface of the forewing white and the other half yellow; the white distal half has a narrow yellow margin. The proximal part of the hindwing is reddish yellow, shading into greenish distally, a broad margin is white. The under surface of the forewing is in the anterior part yellowish with dark submarginal markings, in the posterior part whitish. The proximal part of the hindwing beneath is reddish white, the margins are greenish, the distal margin broadly so; there are no markings except two white spots at the discocellular and a few small blackish submarginal markings. The ♀ has dingy reddish yellow upper surface with continuous black marginal markings, large black median spot and a small hook-shaped submarginal spot on the forewing. The hindwing has larger disconnected black marginal spots. The under surface is reddish yellow in the proximal part, in the distal part almost white with reddish marginal markings, blackish submarginal markings, large reddish median spot on the forewing and two white, brownish-edged median spots on the hindwing. — *neleis*. **neleis** *Bdv.*, from Cuba, Mexico and Guatemala, has the distal part of the upper surface less strikingly white and there are no markings on the under surface, which is yellowish on the proximal half and whitish on the distal half. The ♀ is above much lighter, more yellowish and with less black markings, the ground-colour of the under surface lighter. — *butleri*. **butleri** *Scudd.*, from Mexico (Tehuantepec), is apparently only an aberrant female with light chamois-coloured upper surface and the markings somewhat more brown-black. — *hartonia*. **hartonia** *Bth.*, from Jamaica, is in the ♂ above very similar to *godartiana*, only the greenish tinge is wanting; the under surface is quite similar to that of *neleis*, but has somewhat dark markings. The ♀ is similar to the *neleis*-♀, but has no continuous marginal markings on the forewing above. On the under surface the forewing is more yellowish, the hindwing more reddish, also less marked.

orbis. **C. orbis** *Poc'y* (26a) from Haiti and Cuba, is very peculiarly marked in the ♂ above. The orange-yellow colouring, which is spread over the whole upper surface in the ♀, is only present in the ♂ in a large circular spot near the base. The distal half of the forewing is white, the rest of the wing yellow. The hindwing is yellow, with broad white distal margin. The underside is reddish yellow with a white, reddish bordered median spot on each wing, reddish marginal line and red-brown submarginal markings. The ♀ is entirely orange-yellow above and has black marginal and submarginal spots and also a square black median spot. The under surface is more strongly marked with red-brown than in the ♂. The pupa is comparatively slender, without anything striking in its form, the head-part produced into a short point. Larva on *Poinciana pulcherrima*, green with yellow venter, all the incisions light greenish yellow. Pupa green, canoe-shaped, extremities pink and veins yellow (BOISDUVAL).

21. Genus: **Gonepteryx** *Leach.*

The few species of this genus would be better united under the generic name of *Anyptia* *Srauns.*, since they not only differ from *Gonepteryx*-species of the Old World by their gigantic size, but also possess structural characters which well separate them from *Gonepteryx*. The fourth subcostal vein does not run into the costal margin, as in true *Gonepteryx*, but into the much more produced apex. According to E. REUTER the American species agree in the structure of the basal joint of the palpi, but differ in this from the true *Gonepteryx*-species. The species which belong here cannot be mistaken on account of their wing-contour, and possess a further common characteristic in that the subcostal of the hindwing appears especially developed on the under surface and is particularly conspicuous by its peculiar colouring. The secondary male characters agree with *Catopsilia*; but are even more developed, the greater part of the wing above being covered with chalky scent-scales, whilst the scent-organ at the costal margin of the hindwing takes the form of a long, broad gland. One species is distributed from Paraguay, the other two have a more restricted range. — Nothing appears to be yet known as to the earlier stages.

menippe. **G. menippe** *Hbn.* (= *leachiana* *Godt.*) (26g) apparently occurs in the whole of tropical America, not even shunning the higher mountains. It surpasses the most conspicuous Indian Pierid, *Hebomoia glaucippe*, both in size and in beauty. The upper surface is light yellow, sometimes somewhat darker, the apical third of the forewing is gorgeous orange-yellow, at the discocellular is placed a large, square brown-red spot, before it sometimes also a smaller, but otherwise similar spot. The black-brown distal margin varies very much in width; in most specimens it is as shown in our figure, not infrequently it is reduced to marginal spots which are only connected by a marginal line, occasionally it is entirely absent: ab. **calypso** *form. nov.* The hindwing has only rarely blackish marginal spots. The ground-colour of the under surface is likewise rather variable, from greenish white to yellow, with more or less sharp, light, somewhat opalescent markings; there are always on both wings an oblong, much interrupted reddish median spot and a more or less complete row of black submarginal dots; the sub-

costal of the hindwing is conspicuous by its colouring. The ♀ differs in the orange-yellow spot being somewhat lighter and has also more blackish spots at the distal margin of the hindwing. Specimens in which the orange-yellow spot is entirely absent are rare: ab. **thetis** *form. nov.* — FRUHSTÖPFER has based the subspecies **metioche** *thetis, metioche.* on 2 specimens from Colombia; it is said to be characterised by darker, deeper and more uniform yellow ground-colour, longer and narrower wings, larger size, larger, lighter and more divided median spots on the under surface.

G. clorinde *Godt.* (= *swainsonia* *Swains.*, *godarti* *Perty*, *maerula* *Hbn.*) (24g) is distributed from Mexico *clorinde.* to Paraguay, extremely variable in size, has the upper surface white with a faint greenish tinge, the large median spot is either orange- or sulphur-yellow, on each wing is a small black median spot margined with red-yellow. The under surface is greenish with white striation and an inconspicuous reddish median spot on each wing. The ♀ differs in having the yellow median spot much less developed and the median spots larger and much more broadly surrounded with red-yellow. — **nivifera** *Fruhst.*, from Central America, is said to be distinguished *nivifera.* by snow-white upper surface, darker, more orange-yellow median spots and yellowish-marbled under surface.

G. maerula *F.* (24g) is distributed from Mexico to South Peru, but appears to be wanting in the east *maerula.* of the district. The upper surface is lemon-yellow and has no markings except the black-brown median spot and perhaps a few black marginal dots. The scent-organ on the hindwing is lighter. The under surface is greenish with light striation and a white, reddish-bordered median spot on each wing; the subcostal of the hindwing is distinctly prominent. The ♀♀ are mostly whitish and have a larger orange-yellow median spot on the hindwing. A canary-yellow ♀-form is more rare: ab. **flava** *form. nov.* — To **lacordairei** *Bdv.* (= *ecclipsis* *Cr.*) belong *flava, lacordairei, gueneana.* those specimens which have a plain yellow under surface without striation. — **gueneana** *Bdv.* is still less different; specimens with distinct black marginal spots should be referred here.

22. Genus: **Kricogonia** *Reak.*

This genus has its area of distribution from southern North America to Venezuela and also occurs on the Antilles. Apart from the much smaller size and the shape of the wings the only difference from *Gonepteryx* is that the long palpi extend far beyond the head. There is no difference in the neurulation. The early stages are still unknown.

K. lyside *Godt.* occurs from Texas and California to Venezuela. The upper surface is white, the proximal *lyside.* part of the hindwing suffused with yellowish, the basal part of both wings yellow, the under surface slightly yellow except for the almost white posterior part of the forewing, with no markings, only occasionally a black median spot on the hindwing. The ♀ has less yellow at the base and the apex of the forewing is darker. — **terissa** *Luc.* (= *lyside* *Hbn.*) is an aberration which is distinguished by a small black stripe at the costal margin *terissa.* of the hindwing. — **xanthophila** *form. nov.* (26d), from Guatemala, is an entirely yellow form (only in the fe- *xanthophila.* male?). The underside of the hindwing is light, contrasting with the forewing. — **castalia** *F.* is the form from *castalia.* Jamaica. It has at the base only traces of yellow, and the under surface, especially of the forewing, is even less yellow.

K. fantasia *Btlr.* (26d), from Nicaragua, has in the female greenish white upper surface, at the costal *fantasia.* margin of the forewing a dark sulphur-yellow basal stripe and light brown apical and distal-marginal markings, the hindwing is light sulphur-yellow. The underside of the forewing is glossy sulphur-yellow on the basal half, the rest of the wing is light sulphur-yellow, hindwing as above, in the basal half darker sulphur-yellow. Is probably only another aberration of *lyside*; a quite similar specimen from Cuba is before me.

23. Genus: **Teriocolias** *Röb.*

It is not practicable to allow *atinas* *Hew.* to remain in the genus *Terias* as it is much less closely allied to this than to *Colias*. It differs from the latter in that the fourth subcostal vein does not run into the distal margin but direct into the apex and that the lower discocellular of the forewing is wanting; the lower radial arises direct from the subcostal. A fourth peculiarity of this genus is the clothing of the basal half of the antennae with long, hair-like, moderately appressed scales, so that the antenna when only a little magnified gives the impression of a Heterocerous antenna. Similar structures occur among the Erycinids, and also in the American *Gonepteryx* and *Catopsilia*, but not, so far as I can ascertain, in *Terias*. Biological reasons are also against its near relationship to *Terias*: that is to say, *atinas* flies in the high mountains, where species of *Terias* never occur.

T. atinas *Hew.* (26d), from Bolivia, is above deep sulphur-yellow with a small black spot at the disco- *atinas.* cellulars of the forewing, the basal part of both wings is black, at the distal and costal margin of the forewing near the apex are placed small dark spots or dots. The under surface of the forewing is sulphur-yellow with reddish distal margin and small dark marginal spots as well as two black dots at the discocellulars, the under

surface of the hindwing is yellow, densely dusted with brownish and with red-brown spots at the costal margin and in the middle and two blackish dots at the discocellulars. The ♀ has lighter ground-colour. — *pacis* *Stgr.* i. l. (26d), from Peru (3300 m), is above somewhat deeper yellow, beneath the reddish border of the forewing is broader and the hindwing is more deeply dusted with red-brown. — *plesseni* *subsp. nov.*, from Chanchamayo (Peru), was captured by Baron G. VON PLESSEN on March 26 1906 on the way from Aroya to La Merced on the eastern slopes of the Andes, where the species was flying together with *Colias euxanthe* over lupine-fields. It is above and beneath sulphur-yellow, has beneath no differently coloured border to the forewing and shows only a little blackish dusting on the sulphur-yellow ground-colour apart from the blackish brown spots of the hindwing.

24. Genus: **Colias** F.

About three-fourths as many species must be referred to the American Region as to the Palaearctic if the conception of species is not applied too critically. But on a more thorough examination scarcely more than twenty American species can be established, hence about half the number which the Palaearctic Region produces. Considering the enormous size of the region this suggests an apparent poverty in species in America, which however is explained when we remember that the species of *Colias* are in great part inhabitants of the mountains, and the American Region properly shows only one mountain range, although an enormous one. The splitting up of Central Asia into a number of independent mountain ranges has apparently been very favourable to the formation of *Colias*-species. This advantage is wanting in the American Region. On the other hand it must further be taken into consideration that the most southern part of America possesses a few species, some of them very conspicuous, for which the eastern hemisphere can offer no equivalent owing to the want of corresponding lands.

The genus *Colias* is unmistakeably characterised by its superficial appearance; whether the species comes from the far north or the extreme south it is immediately recognised as a *Colias*. In neurulation its special characteristic is the entire absence of the precostal, in which the genus agrees only with the superficially very different *Terias*. The butterflies are mostly of medium size, some species are among the larger Lepidoptera. Antenna rather short, with gradually thickened, but distinct club. Apex of the forewing rounded, forewing with four subcostal veins, of which the first arises far before the discocellular; the upper radial arises from the subcostal, hence the upper discocellular is wanting.

The genus has its principal area of distribution in Central Asia, where most of the species have their habitat. It is almost exclusively confined to districts with a temperate climate. In North America, in the mountains of tropical South America and in the plains of the southern part of South America, as already said, a large number occur, in Africa only two species (local forms of Palaearctic species), but in the Indo-Australian Region, except in the Himalayas and the Nilghiri Hills, no species occurs. A few species extend far towards the north (e. g., *C. boothii* to lat. 75°), and in Tierra del Fuego occurs one of the largest and most beautiful species (*imperialis*). A few species occur in two generations, but most in only one. Sexual dimorphism is well developed in most of the species, also dimorphism in the ♀♀, which often occur in a pale and in a bright yellow or orange-coloured form. Their flight is very quick and long-sustained. The ♂♂ of many species possess as secondary sexual character at the costal margin of the hindwing above a more or less sharply defined small disc of thick chalky scales („Mehlfleck“). — Egg cylindrical, feebly ribbed. Larvae long, of almost equal width throughout, with very short hairs; they hibernate, live mostly on clover and allied plants, the species indigenous to the north mostly on *Vaccinium*. Pupa with pointed head and raised, very sharp dorsal side of the thorax; like most Pierid pupae they are placed upright, are hooked at the cremaster into a silken pad and are held upright by a long, loose girdle.

palaeno. **C. palaeno** L. (= *philomene* Hbn., *lapponica* Stgr., *werdandi* H.-Schäff.) (27a). I have before me a ♂ from Canada, from the collection of Herr LEOPOLD HARTMANN of Würzburg (to whom I am indebted for the loan of his North American Pierids). It is above not distinguishable from German specimens (*europome* Esp.), but much more yellow on the under surface; the colouring of the hindwing approximates to that of the ♀♀ of *pelidneides*. *europome*. — At Hudson's Bay and in Alaska occurs **pelidneides** Stgr., which according to STAUDINGER differs from *palaeno* in that the median spot of the hindwing beneath is not white, but reddish as in *pelidne*; *pelidne*, however, commonly varies in this, yet this median spot is always much smaller in that species than in *palaeno*. — Larva sea-green, velvety, with fine black dots, at the sides a bright yellow longitudinal stripe margined with black beneath, below which the white, black-edged spiracles are placed, venter and ventral legs dull green, thoracic legs yellowish, head green; on *Vaccinium uliginosum*. Pupa greenish yellow with strongly convex dorsum. In the Palaearctic Region the butterfly flies from the end of June to the middle of August on marshy ground.

pelidne. **C. pelidne** Bdr. (= *anthyale* Stgr.) (27a), from Labrador and boreal North America, is paler yellow than *palaeno*, and has narrower and less dark distal margin, the under surface is likewise much paler, greenish

on the hindwing, the median spots of the under surface are smaller, as also those of the upper surface, the latter often absent. The ♀ is above yellowish white with only narrow, proximally diffuse dark margin to the forewing. — *labradorensis*. **labradorensis** Scudder can scarcely be distinguished. The ♂ has narrower distal margin, which is almost broken up into spots by small stripes of the ground-colour, and the ♀ has no dark distal margin. ab. **moeschleri** Gr.-*moeschleri*. Grsh. is darker yellow, almost orange-yellow. — In Dr. STAUDINGER'S collection there are specimens which might be treated as hybrids of *pelidne* and *nastes*; upper surface greenish yellow, veins black-brown, the dark margin sharp. This form may be named **standfussi**. — *pelidne* is not a constant form, but on the other hand does not vary very much, so that no positive characteristics can be given for **skinneri** Barnes. — **chippewa** Edw., from the Mackenzie River (British North America), appears to be a transition between *pelidne* and *palaeno*; STRECKER considers it a form of *palaeno*; it is an aberration very difficult to differentiate. The ♀ is more like a ♀ of *palaeno* than of *pelidne*. *standfussi*. *skinneri*. *chippewa*.

C. philodice Godt. (= *dorippe* Godt., *palaeno* Cr., *europome* Steph.) (27a) (the Common Sulphur or Puddle Butterfly), is distributed from New England to Florida and westwards to the Rocky Mountains. This species is very common and often occurs in swarms, enlivening the edges of the roads and clover fields. It only varies a little in the width of the black margin. White ♀♀ are distinguished as ab. **alba** Stgr. i. l. — ab. **anthyale** Hbn. is a form with narrow dark margins. — In Guatemala occurs **guatemalena** Stgr. i. l., a deeper yellow form with somewhat broader dark margin to the upper surface. The under surface is somewhat more strongly dark-marked. — *philodice*. *alba*. *anthyale*. *guatemalena*. Egg light yellow to red, iridescent. Larva slender, green, with light green longitudinal stripes; lives on clover. Pupa light green.

C. chrysomelas Hy. Edw. (27a, b), from the coast districts of North California, is larger and in the male more glossy, also with broader dark margin than *philodice*. The under surface is dark orange, light yellow in the middle of the forewing. The ♀ is much lighter yellow and has in the broad distal margin of the forewing larger, but diffuse yellow spots. The under surface is light yellow. *chrysomelas*.

C. hageni Edw. (27b), from Canada, has the forewing narrow and pointed, particularly in the male. The upper surface in the ♂ is beautifully yellow, the black distal margin of the forewing, contrary to that of other allied species, broadest at the inner angle. The ground-colour of the under surface is but little different from the upper. The ♀ is grey-yellow, has broader grey-black distal margin, in which large yellow spots are placed, the under surface is grey-yellow. *hageni*.

C. alexandra Edw. (27b) (the Alexandra Sulphur), from Colorado, is in the ♂ above similar to *philodice*, but has more glossy yellow ground-colour with orange-yellow tinge, particularly on the hindwing. The under surface, however, is very different in both sexes, namely silver-grey on the hindwing with silvery median spot. The ♀ is light yellow, has a small dark distal margin to the forewing or none at all, but black median spot, and is sometimes suffused with orange-yellow. *alexandra*.

C. edwardsii Edw. (27b), from Virginia, has the upperside lemon-yellow mixed with orange, with narrow dark margins. The under surface is as uniform as in *alexandra*, but yellow, sprinkled with black on the hindwing, the distal margin is reddish. Probably a form of *alexandra*. *edwardsii*.

C. harfordi Hy. Edw., from California, is lighter yellow above, with narrower dark distal margin, intersected by the yellow veins, and is still less marked beneath, in the female showing the beginning of a submarginal macular band on the forewing and narrower distal margin (proximally dentate) than **barbara** Hy. Edw. (27b, c), which also occurs in California. The lemon-yellow ♂ has narrow dark distal margins, the almost sulphur-yellow ♀ only a diffuse distal margin to the forewing. The under surface is similar to that of *philodice*. *harfordi*. *barbara*.

C. boothii Curt. (27c), from arctic America (*Boothia felix*), occurring up to lat. 75°, appears to be very rare. The markings in the sexes are not so different as is the case in the allied species. The ♂ has besides the dark distal margin on the forewing an almost complete submarginal band and on the hindwing the beginning of one. The under surface, particularly in the ♂, is strongly greenish. In ab. **chione** Curt. (as in the Palaearctic *nastes* ab. *insignata*, vol. I, pl. 25c) the dark distal margin of the forewing is wanting. — Flies from the middle of July to the middle of August and is fond of resting on the flowers of *Oxytropis arctica* and *campestris* (CURTIS). *boothii*. *chione*.

C. interior Scudd. (= *occidentalis* Scudd., *emilia* Edw., *astraea* Edw.) (27c), from South Canada and the Rocky Mountains (the Pink-edged Sulphur), is very similar to *philodice*, but the dark distal margins are much narrower and the yellow ground-colour runs into them in streaks, the fringes are rose-red. On the under-side the apex of the forewing and the anterior part of the hindwing are rusty orange-yellow. The ♀ has almost white upper surface and broader, but diffuse, distal margin to the forewing. *interior*.

C. scudderi Reak. (27c) (= Scudder's Sulphur), from Colorado, Utah, Montana and British Columbia, has broader, but grey-besprinkled dark distal margin. The ♀ is usually white, very rarely yellowish, and has only traces of dark margining. The under surface of the ♂ is yellow, dusted with grey-green at the *scudderi*.

apex and distal margin of the forewing as well as on the hindwing, particularly at the costal margin. The silvery median spot of the hindwing is edged with reddish. Larva on bilberry and willow. EDWARDS' attempt at breeding was unsuccessful, as the larvae died during the winter. — The butterfly flies in July at an altitude of 9000 ft.

nastes. **C. nastes** Bdv. (27d) (the Arctic Sulphur), from Labrador, Greenland, Alaska and the Rocky Mountains in British Columbia, is dark grey-green with grey-black margins and red fringes. The ♀ is more yellowish and has more distinct yellowish submarginal spots on both wings. The under surface of the forewing is impure whitish, with greenish yellow scales, the rose-red fringes are conspicuous, the hindwing is yellowish green, lighter at the margin, the white median spot is bordered with red and distally to it is placed a diffuse red spot, the rose-red fringes are broader than on the forewing. The ♀ has a somewhat lighter under surface and on the forewing some small black submarginal spots. — **rossii** Gn., from Boothia felix, has in the ♂ a gold-yellow centre to the forewing above, the ♀ is white. — **hela** Strecker, **moma** Strecker and **streckeri** Gr.-Grsh., from Hudson's Bay, are aberrations which cannot be accurately fixed, as the species varies as strongly in America as in Lappland (*werdandi*).

behri. **C. behri** Edw. (27d), from the mountains in the west of North America, principally of California, is a very variable species. The ♂ is above yellowish green, densely and regularly powdered with blackish, with conspicuous yellow median spot on the hindwing. The dark distal margin is indistinct on the forewing, but sharply defined on the hindwing. The fringes in the ♂ are yellowish, in the ♀ rose-red. The under surface in the ♂ is green-grey, the median spot is indistinct on the forewing, but on the hindwing conspicuous, as above, the costal margin of the hindwing is red. The ♀ has darker under surface and red fringes.

imperialis. **C. imperialis** Btlr. (27d), from Tierra del Fuego (Port Famine), is in both sexes so characteristically marked that it is impossible to confuse it with any other known species. Upper surface in the ♂ deep orange-red, the distal margin on the forewing broad, occupying fully a third of the wing, but narrower on the hindwing, both wings with large black median spot, inner margin of the hindwing yellow, under surface greenish yellow, middle of the forewing orange with light-centred black median spot and black submarginal markings and similar ones at the inner margin, hindwing with orange-red median spot and indistinct orange-yellow spots round the discocellular. ♀ less vivid orange with broader marginal markings, in which orange-red spots are placed, ground-colour of the under surface much more greenish than in the ♂, but with the same markings. The locality of this species has not as yet been established with certainty, but is probably correct.

vautieri. **C. vautieri** Guér. (27e), from Chile, is in the ♂ above orange-red with broad black-brown margin and median spot of the same colour on the forewing, the black-brown margin of the hindwing is much narrower and is suddenly reduced towards the inner angle; the hindwing has a smaller, indistinct dark median spot. The under surface of the forewing is orange-red, at the margins and particularly at the apex yellowish, and has a black median spot and a submarginal row of black spots, which are larger posteriorly. The under surface of the hindwing is yellow, slightly orange in the middle, the reddish median spot has a light centre, a reddish diffuse spot is placed at the base of the wing and in addition there is a row of small reddish submarginal spots; the inner margin is greenish. The ♀ has above yellowish white ground-colour, broader dark distal margins on both wings and light submarginal spots. The ground-colour of the underside of the forewing is impure white, of the hindwing yellowish. ab. **rutilans** Bdv. are ♂♂ with broader dark margin.

cunninghami. **C. cunninghami** Btlr. (27e), from Ecuador, is only known in the male. Similar to *vautieri*, but larger, apical and distal-marginal border narrower, fringes orange-yellow. Under surface differing but little from that of *vautieri*, the reddish spots of the hindwing larger, the black spots of the forewing on the contrary smaller, fringes rose-red.

minuscule. **C. minuscule** Btlr. (27e), from Ecuador, is apparently nothing but a „miniature edition“ of *cunninghami*. The ♀ has white ground-colour, is similar to the *vautieri*-♀, has on the upper surface of the hindwing less marginal marking, but is more strongly marked on the under surface, particularly of the hindwing.

meadi. **C. meadi** Edw. (27d), from the mountains of Colorado, has orange-red ground-colour and almost uniformly broad, light-sprinkled, dark distal margin. In the ♂ the median spot of the forewing is only indicated, in the ♀ distinct, with light centre. The latter has small yellowish spots in the dark distal margin. The under surface is strongly yellow, in the middle of the forewing orange-red with conspicuous white, red-bordered median spot on the hindwing, less conspicuous dark median spot on the forewing and rose-red fringes. No white ♀♀ seem to occur in this species. — Larva on clover, not different from the *elis*-larva. Pupa shaped like that of *philodice*, colouring green-yellow, ventral side more vivid than dorsal, head-projection yellow, a dark dorsal costal line, small whitish spots on the whole body, wing-cases granulated. — Flies in July.

elis. **C. elis** Strecker (Strecker's Sulphur) (27f), from the western mountains of North America (Rocky Mountains), has brilliant orange-red ground-colour and much narrower dark distal margin than *meadi*. The ♀ has paler ground-colour and much more yellow submarginal marking. The under surface is more sombre on

account of the dark scaling. According to STRECKER white ♀♀ also occur. The larvae hatch at the end of July, in captivity they pupate in the middle of April. The full-grown larva is dark yellow-green, on the back somewhat lighter than at the sides, densely covered with short black hairs which are placed on small tubercles, each of which is surrounded with whitish, on each segment a black spot (occasionally absent), above the legs a white stripe, head light green. Pupa like that of *meadi*.

C. eurytheme Bdv. (= *amphidusa* Bdv.) (27f) is distributed from Canada to Mexico and from the Atlantic to the Pacific; the species does not appear to ascend high in the mountains. It is extraordinarily variable. — In *hecate* Weeks the wings are apparently somewhat more pointed, the veins in the apex of the forewing are less prominently yellow, the ground-colour is somewhat deeper orange-red. ♀-ab. **alba** Weeks is distinguished from the similar *eurytheme*-form ab. **albina** (= *alba* Stgr. i. l.) by more sharply defined and rounder white spots in the dark distal margin. — **keewaydin** Edw. is the winter form with paler ground-colour in both sexes; the ♂ has often a narrower dark distal margin. — The summer form **eriphyle** Edw. (27e) has yellow ground colour and is above only distinguished from *philodice* by the yellow veins in the apex of the forewing. — **ariadne** Edw. (27f) suggests a distinct species on account of the localized distribution of the yellow and the orange-red colouring and by the narrow distal margin. — **californiana** Mén., from New California, is compared by the author with the European *edusa*; in the description no definite differential characters are given; the under surface is said to be as in *myrmidone*. — **autumnalis** Cock. is similar to *eriphyle*, but smaller, with narrower margins, the hindwing is more grey-green. Flies in the autumn and spring. — Full-grown larva with dark velvety green back, on each side a narrow white line, on which are placed irregular shiny vermilion spots, some of them being shaded with orange-yellow. Under surface green. Pupa green with a stigmatal yellow line, above which on each segment is placed a brown dot, a subdorsal brown spot, which begins at the margin of the wing-cases and occupies two or three segments. Egg greenish white, transparent, pointed at one end and obtuse at the other, longitudinally ribbed, with oblique stripes between.

C. christina Edw. (27f, g), from the Slave River, has slight orange-red ground-colour and is conspicuous by the yellow basal part of both wings. The underside has no markings except the median spot. The ♀ is almost white, its forewing with only a little dark dusting at the distal margin and black, white-centred median spot.

C. lesbia F. is distributed from South Brazil (Rio Grande do Sul) southwards and westwards into the high mountains. Specimens from South Brazil, Uruguay and Argentina differ so little that they cannot be separated. This form is in the male dark orange-yellow, specimens with violet reflections are not rare; the black-brown distal margin is not sharply defined proximally. The under surface with the exception of the reddish middle of the forewing is vivid yellow with the usual *Colias*-marking. The ground-colour of the upper surface in the ♀♀ is very variable: orange-yellow, yellow, yellowish or white with grey dusting; greenish grey specimens also occur. The white ♀-form has the name ab. **heliceoides** Capr. Probably the name **pyrrhothea** Hbn. (27g) applies to the form from South Brazil, Uruguay and Argentina, whilst the paler specimens from Patagonia should be regarded as the true *lesbia*. — **andina** Stgr., from Bolivia (3000—4000 m), is sprinkled with blackish and has a larger reddish basal spot on the underside of the hindwing. — **arena** Stgr., from Tierra del Fuego (Punta Arenas), has narrower forewing with more pointed apex, light orange-yellow upper surface and broader dark distal margins. — **antarctica** Stgr., from Tierra del Fuego, is a white ♀-form with unspotted distal margin. — **puna** Fruhst., from Peru (Puno, 12 500 ft. elevation), has rounder wings, more thickly and darkly scaled, and narrower dark distal margin to the hindwing. — Flies from November to January. CH. DARWIN observed a large swarm of these butterflies in Patagonia.

C. hecla Lef. (= *boothii* Bdv., *groenlandica* Rühl., *glacialis* Mc. Lachl., *hela* Strecker) (27 g) occurs in Greenland and extends there to lat. 82°. It differs from the Palaearctic form *subiterna* Auriv. by dark, duller ground-colour; the under surface has the same character. — **pallida** Skinner & Mengel is a lighter form.

C. dinora Kirby (27 g), from Ecuador (12 000—16 000 ft.), is orange-yellow, with washed-out, moderately broad dark distal margin to the forewing; the hindwing has a submarginal row of small, dark, inconspicuous spots. The under surface on the forewing is somewhat lighter, on the hindwing somewhat darker than the upper, the median spot is white, small and margined with reddish. The ♀ has lemon-yellow ground-colour and yellow spots in the dark distal margin of the forewing — **alticola** Godm. & Salv., from Peru (3000 m), is larger, has somewhat blue reflections, darker and broader distal margin to the forewing, also narrower distal margin to the hindwing, more distinct median spot, sharper yellow colour on the basal part of both wings and somewhat lighter, but more strongly marked under surface.

C. flaveola Bl. (27 h), from Chile and Bolivia (mountains), is pale orange-yellow in the ♀, in the rather broad dark distal margin of the forewing are placed four large yellowish white subapical spots, the under surface has dull sulphur-yellow ground-colour. Deeper orange-yellow coloured female specimens are common and may be designated ab. **saturata**. — **euxanthe** Fldr. (= *Scalidoneura hermina* Btlr.) (27 h), from Peru, differs but little. The upper surface is deeper coloured and the under surface more strongly marked. White ♀♀ go by the name ab. **alba** Stgr. i. l.

dimera. **C. dimera** Dbl. & Hew. (= *erythrogramma* Koll.) (27 h) is likewise a mountain species indigenous to Colombia, Peru, Ecuador, etc., and apparently little variable. The upper surface of the forewing is orange-yellow, that of the hindwing lemon-yellow. The dark margin of the forewing is moderately broad, that of the hindwing somewhat variable, occasionally it is entirely wanting, as also the black median spot of the forewing. The under surface is sulphur-yellow and has a row of reddish submarginal spots, a diffuse spot at the base and a white, red-bordered median spot on the hindwing. The ♀ is above and beneath yellowish white.

25. Genus: **Meganostoma** Reak.

The species of this genus were formerly united with *Colias*. But apart from differences in neuration the *Meganostoma*-species are even superficially characterised by the sharply pointed forewing. The ♀♀ have an organ which is only observable in newly emerged specimens on account of its being so very perishable, namely soft, membranous, three-jointed structures on the tarsi of the middle and hindlegs, which have been named eupronechiae by their discoverer REAKIRT. Their purpose is not known. *Meganostoma* is further well differentiated from the other Pierids by the absence of a pad between the claws. The larvae live on Leguminosae.

eurydice. **M. eurydice** Bdv. (= ♀ *lorquini* Bdv., *wosnesenskii* Mén.) (26 f) (the Californian Dog-face), from California, has in the male a brilliant sheen on the upper surface only rarely occurring in Pierids. Occasionally also the hindwing has a narrow black distal margin. The ♀ is unicolorous yellow with a large black median spot on the forewing and reddish marginal spots. The marking of the under surface in both sexes is thoroughly *Colias*-like. The larva lives on *Amorpha californica*. Egg spindle-shaped, thick in the middle, running out into a rounded point, with longitudinal ribs. Full-grown larva cylindrical, of uniform thickness from segment 3 to 11, densely covered with small black tubercles, on each of which a very fine black hair is placed, from segment 3 to 11, a narrow white band above the legs, above this band on the 3. and 4. segments, in the middle of each segment, is a glassy, semicircular appendage, black with purple reflection; on the remaining segments this structure is only occasionally found. Colour dark green, underside blue-green, also the legs; head round, only a little depressed at the vertex, strongly covered with fine black dots, each of which bears a short black hair. Pupation takes place six days after the larva ceases to feed. Pupa laterally compressed, the thorax projecting on the ventral side and forming a narrow prominence, abdomen pointed, conical, mesothorax less projecting than in *C. eurytheme* and *philodice*, low, rounded, with a low keel, behind which there is a slight incision. Head apple-green, a white stripe at the sides of the abdomen. Duration of the pupal stage nine to ten days.

cesonia. **M. cesonia** Stoll (= *sesonia* Mart., *caroliniana* Pet.) (26 f) (the Southern Dog-face) is distributed from the United States of North America to Argentina. The ♀ has reduced marginal marking, the black marking at the distal margin of the hindwing is always absent. — **cesonides** Stgr., from Bolivia (3500 m), is smaller, *cerbera*. has narrower black distal margin, and the black dusting at the base is almost entirely absent. — **cerbera** Fldr., from Venezuela, has on the under surface of the hindwing red longitudinal stripes (is doubtless only an aberration). — **rosea** Stgr. *i. l.*, from Colorado, has small black stripes instead of the black distal margin of the hindwing. — **centralamericana** Stgr. *i. l.* has very broad black margin also to the hindwing and on the latter orange-yellow spots before the black distal margin. — **bernardino** Edw. is only a small form.

philippa. **M. philippa** F. (26 e), from Bolivia, has in the ♂ the apex of the forewing rounded, in the ♀ on the contrary it is rather pointed. In the marking there is no constant difference.

cynops. **M. cynops** Btlr. (26 e), from Haiti, has the apex of the forewing rounded in both sexes. The ♂ has broad black margin, in the ♀ this is broken up into spots.

helena. **M. helena** Reak. (26 e), from Bolivia, has, especially in the female, the forewing very sharply produced. The ♂ has no black margin to the light orange-yellow hindwing, in the ♀ the hindwing is likewise without markings except the yellow median spot and on the forewing the margin is broken up into spots. The under surface in both sexes has a considerable amount of red marking.

therapis. **M. therapis** Fldr. (26 f), from Venezuela and California, has the forewing sharply pointed. The ♂ is lemon-yellow, the ♀ light sulphur-yellow. Both have strongly reduced distal-marginal marking and on the under surface much red marking.

Very probably the genus *Meganostoma* has only two species, *eurydice* and *cesonia*; all the other forms described above I should consider only aberrant forms or slight local modifications of *cesonia*.

26. Genus: **Nathalis** Bdv.

This genus only embraces two small species, of which even the superficial appearance forbids any confusion with other genera. The antennae have strikingly knob-like clubs. The palpi are rather hairy than scaled and the subcostal has three branches, two of which branch off before the discocellular.

N. jole *Bdv.* (= *felicia* *Poey*) (27 h), from the southern States of North America, Mexico, Colombia *jole*, and Cuba, is lemon-yellow with black apex and black innermarginal stripes on the forewing, also at the costal margin of the hindwing there is a long black spot. The ♀ has the upper surface of the hindwing pale orange-red. ab. **irene** *Fitch* (27 h) is a ♀-form with the hindwing deeper orange-yellow and more strongly marked *irene*, with black. — **luteolus** *Reak.*, from Honduras, is a more orange-yellow form, strongly marked with dark. *luteolus*.

N. plauta *Dbl. & Hew.* (27 h), from Venezuela and Colombia, has yellow upper surface, very broad black *plauta*, distal margin to the forewing and a large orange-yellow spot at the anterior part of the hindwing. Under surface of the forewing in the middle orange-yellow, at the margin greenish yellow, the hindwing greenish, yellow at the margin. The ♀ has the upperside of the forewing almost black.

27. Genus: **Euchloë** *Hbn.*

Of this genus, which is represented in the Palaearctic Region by nine species, there are only three in the American Region. Antennae and palpi shaped as in the following genus *Anthocharis*. Of the five subcostal veins only one arises before the apex of the cell. The upper radial is coincident with the subcostal almost to $\frac{1}{3}$. — Egg spindle-shaped, with small protuberances at the sides. Larva slender with small head. Pupa pointed at both ends, the breast only a little raised.

E. ausonides *Luc.* (28 a) is distributed from Colorado to California, also occurring on Vancouver Island, *ausonides*. Upper surface white with black median spot and grey-black apical and subapical markings on the forewing. Under surface white with black median spot on the forewing and yellow-green „parsley“-marking on the hindwing and the apex of the forewing. — Larva on Crucifers, cylindrically slender, head small, round, green, black-spotted, body entirely covered with black granules, each of which bears a short hair, longitudinally marked with three pale-coloured stripes, a dorsal one and one at each side, the interspaces yellow, the lateral stripes margined beneath with white to yellow; ventral legs greenish yellow, thoracic legs black. Pupa slender, cylindrical, thickest in the middle, uniformly pointed, grey-brown, and covered with fine dark longitudinal stripes.

E. creusa *Dbl. & Hew.* (28 a), from the Rocky Mountains, is similar to the preceding species, but the *creusa*, black median spot of the forewing is large and square. The markings of the under surface are grass-green and the light spots on the hindwing are silver-white. Almost nothing is known of the early stages.

E. hyantis *Edw.* (28 a), from California, is above very similar to *creusa*, but on the underside of the *hyantis*, hindwing more yellow-green and the spots are there only white but not shiny.

28. Genus: **Anthocharis** *Bdv.*

This genus is only represented in America by four species. It differs from the preceding genus in that two subcostal veins arise before the discocellular. The upper radial is only shortly coincident with the subcostal. Larva slender, narrower at both ends, with soft hairs. Pupa canoe-shaped, with strongly projecting breast (boot-shape), produced into a point at the ends, weakly keeled on the back.

A. sara *Luc.* (= *flora* *Wright*) (28 a) is distributed all over the United States of North America. Upper *sara*, surface white with large orange-red apical spot, which is margined with black distally and proximally. Hindwing white. ab. **reakirtii** *Edw.* (28 a) differs from *sara* by the presence of black dots at the distal margin of *reakirtii*, the hindwing. The ♀ of *sara* has slightly yellowish upper surface and smaller and paler orange spot. ab. **stella** *Edw.* has in the ♂ the bordering round the orange spot less black, also the spot itself is smaller and paler; the ♀ has yellow upper surface. ab. **julia** *Edw.* (28 a) differs from *sara* in that the proximal black bordering of the *julia*, orange spot is interrupted and the hindwing has larger black marginal spots. — Earlier stages unknown.

A. thoosa *Scudd.* (28 a), from California (which is only known to me from the figure), shows in pattern *thoosa*, no difference between the sexes, only the ground-colour of the ♂ above and beneath is white, that of the ♀ yellowish. Is probably scarcely a separate species, but a large, strongly marked form of *sara*.

A. cethura *Fldr.* (= *angelina* *Bdv.*, *cooperi* *Behr*) (28 a), from California, has in the ♂ the distal margin *cethura*, of the forewing somewhat incurved. Upper surface white with small orange spot, very small dark apical markings, and black median spot. ♀ with stronger black markings. ab. **morrisoni** *Edw.* has larger and darker orange *morrisoni*, spot also more black apical marking. — For this species GROTE has erected the genus *Tetracharis*.

pima. **A. pima** *Edw.* (28 a), from Arizona, flies at the middle of March. Upper surface in both sexes yellow, the black apical marking sometimes encroaches more or less on the yellow subapical spot. Under surface of the hindwing yellow-green and marked with white.

29. Genus: **Midea** *H.-Schäff.*

The principal character of this genus consists in the shape of the wings, the forewing is somewhat falcate. The neuration is scarcely different from that of *Anthocharis*. It is therefore purely a matter of opinion whether the following species should be added to *Anthocharis* or associated in a separate genus.

genutia. **M. genutia** *F.* (= *midea* *Hbn.*, *l'herminieri* *Godt.*) (the Falcate Orange-tip) (28 b) occurs throughout the United States, in the north in one generation, in the south in two. Upper surface in both sexes white with black median spot and black apical markings, the ♂ with orange-yellow spot in the apex of the forewing. Under surface white with grey-green markings on the hindwing and the apex of the forewing. — Egg long, narrow, thickest in the middle, moderately rounded towards the base, the latter broad and flattened, suddenly narrowed towards the apex, so that the upper half is conical, the apex impressed, the micropyle surrounded by small, irregular hexagonal cells, vertically ribbed, the number of the ribs about 16, of which half reach the tip and the others terminate not far from it, the interspaces filled up by numerous fine grooves. Colour yellow-green. Duration of the egg-stage four days. Full-grown larva cylindrical, slender, head broad, colour dark yellow-green, shiny, underside, ventral and thoracic legs lighter, a yellow band in the middle of the back from the 2. to the 13. segment, a broad white band above the legs, upperside decorated with six longitudinal rows of shiny black tubercles, each with a short black hair which is thicker at the end. Pupa slender, abdomen long, round and pointed, head with a pointed appendage, on the ventral side of the thorax an almost triangular, laterally compressed lump, which is hidden by the wing-cases; colour usually light yellow-brown with a reddish tinge and darker on the mesothorax, the prolongation of the head brown, the wing-cases more or less spotted and striped with black, at the back of the abdomen a row of small black spots, two to four on each segment, and a subdorsal row of small spots or dots.

limonea. **M. limonea** *Btlr.* (28 b), from Mexico, is much larger than *genutia*, has the upper surface of the hindwing yellow, and the forewing is not pure white as in *genutia*. The marking at the apex of the forewing is rather different from that of *genutia*.

lanceolata. **M. lanceolata** *Luc.* (Boisduval's Marble) (28 b) is distributed from North California to Alaska, but rare. The upper surface is white with black median spot and slight blackish apical markings, which are enlarged in the ♀. The under surface is sprinkled with brown, the veins especially are distinctly scaled with brown. — Larva green, laterally light blue with white stripes, also with small black dots, each with a short black bristle; it lives on *Turritis*.

30. Genus: **Zegris** *Rbr.*

The Palaearctic species of this genus are distinguished by their life-history. The larvae do not pupate free like most other Pierids, but in a cocoon in which traces of the girdle are still present. As the larva of the only American species is not yet known, it cannot be proved with certainty whether it belongs to this genus. But according to the neuration and the marking of the under surface *olympia* belongs to the genus *Zegris*.

olympia. **Z. olympia** *Edw.* (28 b), from Texas, is white above, with large black median spot and small, shadowy apical markings. The under surface has the markings shown in the figure, which are somewhat reduced in *rosa*. ab. **rosa** *Edw.*

31. Genus: **Eroëssa** *Dbl.*

This genus is nearly allied to the Palaearctic and North American *Euchloë* and *Anthocharis*, in it, however, both the radials of the forewing are free and the cell is consequently closed by three discocellulars. The forewing has slightly undulate distal margin and five-branched subcostal, the two first subcostals arise before the end of the cell, the third far behind it. The precostal is directed proximally. The palpi are very slender, anteriorly long-haired. The only species of this genus inhabits the high mountains of Chile.

chilensis. **E. chilensis** *Guér.* (28 c) has white ground-colour on the upper surface, with black apical half of the forewing, in which is placed a large orange-red spot. The hindwing has a row of black marginal and submarginal

spots; in the ♀ the latter are larger and hook-shaped, also the orange-red submarginal spot is narrower and there are two white spots in the apex of the forewing. Beneath the ground-colour of the hindwing in the ♂ is white, in the ♀ light yellow; the black spots placed in the middle of the hindwing are more distinctly edged with rust-yellow in the ♂. Apparently rare and local.

32. Genus: **Andina** Stgr.

This genus, containing only one species, inhabits the mountains of Bolivia at the highest limit at which animal life can exist. The butterfly was discovered by G. GARLEPP at an elevation of about 5800 m. The upper surface of the species presents the appearance of a pale-coloured *Colias*, the under surface is also *Colias*-like, but the veins and the structure of antennae show that it is not very closely allied to this genus. The antennae have distinctly knob-shaped clubs, the lower radial of the forewing arises directly from the subcostal, hence the upper and middle discocellulars are wanting; the upper radial does not arise until far beyond the discocellular. The hindwing has a well developed precostal, directed proximad.

A. huanaco Stgr. (28 c) is in the ♂ white above, the smaller ♀ yellowish, the base suffused with black-*huanaco*. ish, the forewing has a marginal and a shorter submarginal band as well as a large black median spot, hindwing without markings. Under surface of the forewing white resp. yellowish, costal margin and apex dusted with grey, with smaller subapical spots and smaller median spot. Under surface of the hindwing dark grey, more or less dusted with yellow-brownish, with a light median spot and a row of not very distinct blackish submarginal spots. — GARLEPP says: „it flies only on the highest summits of the Cordilleras, amidst the wildest boulders and most desolate masses of rock; I cannot understand its choosing such wastes and deserts, or how it can exist there at all, where it must sometimes be daily covered with snow and ice, where there is absolutely no vegetation, and where only the condor makes his abode“. In these heights a tempestuous wind constantly prevails, so that the insect can only fly in the brief lulls. Was taken in February.

33. Genus: **Phulia** H.-Schäff.

The habits of this genus are almost the same as those of *Andina*, except that *Phulia* does not ascend to the summits of the mountains, but stops at a height of from 4000 to 5000 m. The species fly at the same time as *Andina*. — Whilst in *Andina* the second subcostal vein branches off at the discocellular, in *Phulia* it mostly arises before the end of the cell, occasionally at the cell-end (*nysias*), on the other hand the lower radial is always coincident with the subcostal, though sometimes only for a little way (*nymphula*); the cell is therefore only closed by the lower discocellular. The species are very similar. The genus most nearly allied to this and the preceding one is *Baltia*, from the highest mountains of the Palaearctic Region.

P. nymphula Bl., Stgr. (28 c) has been described from specimens from Chile, but STAUDINGER identifies *nymphula*. a species from Bolivia (that figured as *nymphula*) with it. BLANCHARD'S figure does not appear to be accurate; so long as no Chilean specimens can be compared it remains uncertain whether the form figured is the true *nymphula*. It is one of the larger species of the genus.

P. nymphula Stgr. (28 c, d), from Bolivia, is the largest species of the genus and has also the most mark-*nymphula*. ings both above and beneath. Very striking, particularly in the ♂, is the basally prolonged black median spot on the upperside of the forewing.

P. nymphaea Stgr. (= *nymphula* Weym., *nymphula* Stgr.) (28 d), from Bolivia (Illimani and Cocapota), *nymphaea*. has rather reduced black markings on both surfaces. The ♀, in addition to an increase of the black markings on the forewing, has also rather large, wedge-shaped black spots on the upperside of the hindwing.

P. illimani Weym. (28 d), from Bolivia (Illimani and Cocapota), has somewhat stronger black apical *illimani*. marking, but no subapical one, and the black median spot is wanting. The under surface of the forewing has at the apex grey-yellow dusting only, but no black marking.

P. nymphagoga Stgr. i. l. (28 d), from Bolivia (Cocapota), is one of the smallest species, and has on *nymphagoga* the forewing a considerable amount of black marking, also a black median spot, but in the ♂ the hindwing is entirely without markings. The ♀ has on the forewing more black markings (the marginal macular band reaches to the inner angle) and the hindwing has rather large black marginal spots, also small submarginal spots, and is besides somewhat dark-scaled. The under surface, especially at the apex of the forewing, is more marked with black than in the other small species.

P. nysias Weym. (28 e), from Bolivia (Illimani and Cocapota), is distinguished at once by the under *nysias*. surface of the hindwing, which (as in *Andina huanaco*) is grey with black spots. The ♀♀ are vivid sulphur-

yellow and have more black markings, also on the hindwing small black marginal spots, and the veins of the forewing are dusted with black.

P. nysiella *Stgr. i. l.* (28 d), from Bolivia (Cillutincara, 3000 m), taken by GARLEPP in January 1896, is the smallest species, with broader forewing. Upper surface white, hindwing without markings, forewing with sharply separated small black marginal spots, three larger black subapical spots and very small black median spot. Under surface similar to that of *nysias*, but the hindwing lighter grey, with much yellowish scaling, forewing with small, very indistinct subapical spots, median spot of the forewing absent. ♀ still unknown.

34. Genus: **Pseudopieris** G. & S.

With this genus begins a small group of genera which cannot with certainty be reckoned Pierids and yet can still less be associated with any other family. The position of the last genus *Styx* especially is very doubtful. *Pseudopieris* was formerly united with *Dismorphia*, but has rightly been separated from it. Although there is no decisive difference in the neurulation, yet the much more Pierid-like facies, as well as the form of the short antennae, which do not at all possess the length characteristic of *Heliconius* or the Ithomiids, and also the want of striking sexual dimorphism, present sufficient generic characters. — According to the observations of Herr RICH. HAENSCH the forms of *Pseudopieris* do not differ essentially in habits from the *Pieris*-like *Dismorphias*.

P. nehemia is distributed from Mexico to South Brazil, and also occurs in the mountainous west. Upper surface in both sexes white with black margin to the forewing. This is very narrow in **nehemia** Bdv. (= *cydno viridula*. Dbl. & Hew.) (28 e), only exceptionally somewhat broader. It is not much broader in **viridula** Fldr., from Colombia, which has slightly greenish upper surface. This border is much broader in the apex of the forewing in **aequatorialis** Fldr., from Ecuador. The underside in all these forms is white on the forewing, yellowish on the hindwing and the apex of the forewing. A blackish spot on the discocellulars of the hindwing is occasionally absent in *nehemia*, in the other forms apparently constant.

penia. Whether **P. penia** Hopff. (28 e), from Peru, is a separate species, I must leave undecided. In this form the black apical border is still broader than in *aequatorialis*, but in addition the border is strongly widened in the middle of the distal margin. As there is no blackish spot at the discocellular on the under surface of the hindwing, HOPFFER considers *penia* as a separate species. But as was shown in *nehemia*, the presence or absence of this spot cannot be taken as a specific criterion.

35. Genus: **Dismorphia** Hbn.

This genus is distributed from the southern states of North America to South Brazil and from east to west, especially developed in the western mountains, but most species have not a large area of distribution. All the species differ so considerably both in superficial appearance and in neurulation from their relatives that they cannot be recognised as „Whites“ without further examination. They doubtless represent another branch of the Pierid stirps. Their nearest relatives — with the exception of *Pseudopieris* — are the Palaearctic *Leptidia* and perhaps *Pseudopontia* from West Africa. A great number of the species resemble Ithomiids, Acraeids (*Actinote*) and Heliconines, which are protected by their bad smell and taste, yet cases of deceptive similarity are not common. Sometimes only the female is a so-called mimic. The sexual dimorphism in many species is so great that the identity of the sexes can only be proved with difficulty. — BUTLER not only retained HÜBNER's genus *Enantia* (with *melite* as type), but also erected a further genus, *Moschoneura* (with *methymna* as type). Since there is neither any necessity for such a division, nor are the characters given for these genera tenable, the genus (which is also known under the name *Leptalis* Dalm.) is here retained in the customary extent. — I am indebted for the following biological notes to Herr RICH. HAENSCH, who made observations during his travels in South America, especially in Ecuador: larva and pupa are not known to him. The Ithomiid-like species, such as *orise*, *theonoe*, etc., like the Ithomiids, are fond of the shades of the thick forests of trees, whilst the more brightly coloured ones, *praxinoe*, *astyocha*, are also found in lighter places in the woods. The ♂♂ of the latter when flying assume a position in which the large light spot of scent-scales on the upper surface of the hindwing is covered, so that they, like their ♀♀, are not distinguishable from the similarly marked *Mechanitis*. Forms like *nemesis*, *critomedia*, *leonora*, etc., prefer small clearings in the woods and are fond of resting, with the wings spread out, on the tops of bushes upon which the sun shines. The seasonally common yellow and white forms, such as *medora*, *limnorina*, *Pseudopieris nehemia*, etc., make their appearance at the beginning resp. end of the rainy season often in large numbers on scented umbelliferous flowers by the wayside and at the edges of the woods; they do not differ noticeably from the true Pierids. The mimetic forms are scarcely distinguishable in their habits from the similar Ithomiids; they occur in the same localities as these, but do not fly in company with them. On the other hand their colouring regularly corresponds with the local forms of Ithomiids, which is especially well seen in the *theonoe*-forms.

D. cretacea S. & K. (28 e), from South Brazil (Espírito Santo), has white upper surface with broad black apex, which, especially in the ♀, is strongly sinuate in the posterior part. The hindwing has small black distal border. The under surface is yellowish white, the forewing without markings in the ♂, in the ♀ with a black subapical band and a black spot near the inner angle, the hindwing has 2 black-grey transverse bands, of which one is placed in the centre, the other near the costal margin.

D. isodrita Bdv. (28 e), said to be from Brazil, known to me in one ♀ from Colombia, is scarcely specifically different from *cretacea*. The black apical margin differs but little from that of *cretacea*, but has a very small white subapical spot, the hindwing is entirely without markings. The under surface is more yellow and the black subapical band of the forewing reduced to an indistinctly defined spot.

D. flavia Fldr. (*H.-Schäff. i. l.*), from Venezuela, is similar to *isodrita*, but is said to have shorter wings and narrower cell. Unknown to me.

D. psamathe F. (28 f), said to be from Guiana and Para, only known to me from South Brazil (São Paulo and Santa Catharina), has in the black apex of the forewing a large white spot. The ♀♀ have mostly strongly yellow hindwing. The under surface of the hindwing and the apex of the forewing are light ochre-yellow, the hindwing has 2 grey-black transverse bands, in the ♂♂ the black subapical spot of the forewing is occasionally absent.

D. acutipennis Btlr., from Trinidad, only before me in a ♂ from Colombia, differs from *psamathe* only in having a lighter yellow under surface. — **disjuncta** form. nov. (28 f), from Rio Grande do Sul, is distinguished by the proximal part of the black apical spot being broken up and the under surface as yellow as in *psamathe* (seasonal form of *psamathe*?).

D. mercenaria Fldr. (28 f) comes from Venezuela, I have before me specimens from Peru; whether these are different from Venezuelan specimens I cannot say. It has in the male a somewhat narrower forewing and differently shaped margin to the black apical spots, but is otherwise, especially in the female, not different from *cretacea*.

D. licinia Cr. (= *galanthis* Bates, *phronima* F.) (28 f), from the Upper Amazon (Peru), is distinguished from *mercenaria* by the different shape of the proximal boundary of the black apical spot. The under surface is somewhat lighter yellow.

D. aphrodite Fldr., from Brazil, is above chalk-white, distal margin black-brown with a white spot, hindwing unicolorous. Under surface of the forewing in the ♂ sulphur-yellow in the middle, costal margin and base saffron-yellow, small blackish dots at the costal margin, ♀ unicolorous, costal and hind margins ochre-yellow, black-brown apical band, hindwing in the ♂ ochre-yellow, in the ♀ much lighter, both beneath with brownish stripes. Unknown to me.

D. marion G. & S. (28 g), from Central America and South Brazil (Santa Catharina), is similar to *psamathe*, but has, in addition to the differences in the markings, both wings differently shaped. The under-side of the forewing is less strongly marked.

D. thermesia Godt. (28 g), from Brazil (São Paulo), has the forewing very narrow in the male. In the ♀ the oblong black median spot of the forewing is absent. The under surface is pearly white with dark scale-spots, the ♀ has also black subapical markings on the forewing, which are wanting in the ♂. — **thermesina** Hopff., from Peru, has more black markings.

D. limnorina Fldr. (28 g), from Brazil (Minas Geraes), has peculiar wing-contour. The wings in the ♀ are entirely light yellow, in the ♂ light yellow in the posterior half. The underside has black submarginal markings on the forewing in both sexes, but less in the ♂.

D. dilis Bdv., from Brazil, is similar to *licinia*, but has on the forewing narrower and shorter black markings. Under surface as in *licinia*. Only known to me from the description.

D. theugenis Dbl. (= *colon* Weym.) (28 h), from Bolivia and Peru, has deep sulphur-yellow upper surface with broad black apical marking and black median spot on the forewing as well as black margin to the hindwing. The under surface is sulphur-yellow except for the white posterior part of the forewing, the forewing has a black marginal spot in the middle of the distal margin and the hindwing 3 blackish transverse bands. ♀ unknown to me.

D. melite L. (28 h), from South Brazil (Santa Catharina and Rio Grande do Sul), has canary-yellow upper surface with black marginal and central markings. The under surface as in the allied species is yellow with 2 blackish transverse bands on the hindwing. The ♀♀ have broader forewing and much lighter yellow

jethys. ground-colour, almost white specimens are not rare: ab. **alba** *form. nov.* — **jethys** Bdv. (= *melite* Koll.) („the Mime“ of the North Americans) occurs in Mexico, but probably also further south. This form has additional black markings, such as a stripe from the base to the inner angle of the forewing.

cornelia. **D. cornelia** Fldr. (28 h), from Mexico, has ochre-yellow upper surface with black-brown markings on the forewing and black-brown, irregular distal margin to the hindwing. The under surface with the exception of the whitish posterior part of the forewing is ochre-yellow with brownish spots and dots on the hindwing.

amalia. — **amalia** Stgr. (28 h), from Chiriqui and Colombia, has much less dark marking on the forewing, especially the broad median stripe is entirely absent, and the hindwing has a uniformly broad dark distal margin. The ground-colour is above and beneath lighter.

mirandola. **D. mirandola** Hew. (29 a), from Ecuador and Colombia, has black upper surface to the forewing with yellow markings. The hindwing is clay-yellow on the anterior part (scent-spot), sulphur-yellow on the posterior part, and has black markings. The ♀ has on the forewing more and lighter yellow markings, the hindwing is light sulphur-yellow with black distal margin. The under surface in both sexes is light yellow with silver-white spots and dark dusting. — **cauca** *form. nov.*, from West Colombia (Cauca Valley), has in the ♂ continuous yellow median band on the forewing, more reduced clay-yellow scent-spot on the hindwing, the yellow marking near the base of the forewing wanting.

carthesis. **D. carthesis** Hew. (29 a), from Ecuador, is similar to *mirandola*, but has larger subapical spots on the forewing, no yellow marking near the base of the hindwing, but a larger yellow spot at the inner margin. The hindwing has a narrower yellow median band and much broader black distal margin. The under surface has on the hindwing a broad yellow median band and broad black distal margin, in which are placed reddish white submarginal spots.

idonia. **D. idonia** Hew., from Ecuador, has the forewing similarly marked to that of *carthesis*, but the yellow spot at the inner margin is absent. The yellow median band of the hindwing is more obliquely placed. The under surface is entirely different: the grey-blackish hindwing has two yellow central transverse bands and some small yellow marginal spots.

zaela. **D. zaela** Hew. (29 a, b), from Colombia and Ecuador, has on the black-brown forewing in the ♂ chrome-yellow central and subapical spots. A large part of the hindwing is occupied by a grey scent-patch with a silky gloss, the posterior part of this wing is proximally yellow, distally chrome-yellow, the distal margin black-brown. The ♀ has light yellow markings on the forewing and a light sulphur-yellow hindwing with broad black margin. The under surface in both sexes is marbled with white and grey-brown.

arcadia. **D. arcadia** Fldr. (29 b), from Colombia, is similar to the preceding species, but has in both sexes light canary-yellow markings. On the hindwing the ♂ has one yellow band and the ♀ two. The underside is similar to that of *zaela*, but much yellower.

crisia. **D. crisia** Dru., from „Brazil“, is about the same shape as *arcadia* and the markings are similar. The inner margin of the forewing is whitish, in the ♀ the median spots are smaller. — Only known to me from BOISOUVAL'S description.

medora. **D. medora** Dbl. (♀ = *casta* Koll.) (29 b), from Colombia and Venezuela, has also a yellow spot at the inner margin of the forewing; on the grey, silky scent-patch of the hindwing there is a sharply defined, oval

medorina. grey spot of scent-scales. The ♀ has much broader yellow markings. — **medorina** Hew., from Bolivia, has three larger yellow subapical spots on the forewing and the posterior yellow spot of the median band is separated from the other spots. The yellow band of the hindwing is orange-yellow in the anterior part. — **medorilla** Hew., from Ecuador and Peru, has smaller yellow spots on the forewing and narrower yellow band on the hindwing.

proserpina. **D. proserpina** S. & K., from the Roraima, has above and beneath much lighter (almost white) markings than **demeter** *form. nov.* (29 b), from Colombia and Venezuela, the latter has moreover on the scent-patch of the hindwing no special, sharply defined scent-scale-spot like *proserpina* (separate species?); *proserpina* I only know from the figures and descriptions. The under surface is much yellower in *demeter* but is otherwise not different from that of *proserpina*.

othoë. **D. othoë** Hew. (29 c), from Ecuador and Colombia, is above black-brown with yellowish markings. In the ♀ the markings are more whitish and larger. The underside is pale yellow with blackish scale-markings.

zathoe. **D. zathoe** Hew., from Colombia, is similar to *othoë*, but the median spots are smaller and yellower and the subapical spot is larger and white, also the band of the hindwing is more sharply yellow.

lelex. **D. lelex** Hew., from Ecuador, is somewhat larger than *zathoe* and has paler yellow markings, the median spots of the forewing are larger, on the other hand instead of the one large white subapical spot there are two

small yellowish spots. The hindwing is yellow and has only in the anterior part a proximally dentate black distal margin.

D. pimpla Hopff. (29c), from Bolivia, has the yellow subapical spots differently placed, also yellow *pimpla* dusting at the base of the forewing. The hindwing has the black margin narrow but uniform.

D. pallidula Btlr. (29c), from Costa Rica and Chiriqui, has white markings and a large, grey, oblong *pallidula* scent-patch on the hindwing.

D. lysis Hew. (29c), from Ecuador, has the white markings enlarged, no subapical spots, and the ♀ *lysis* has on the forewing a broad white median band reaching from the costal to the inner margin. The under surface has pearl-white spots and much grey-yellow scale-marking. — **peruana** form. nov., from Peru, is somewhat smaller, paler black and beneath with grey instead of yellow scales.

D. foedora Luc. (29d), from Venezuela and Peru, is white above with broad black apex and two sub-*foedora* basal stripes, of which the posterior one is joined to the border of the distal margin; the hindwing has a moderately broad black border. The ♀ has on the forewing less black marking, on the other hand almost the whole posterior half of the hindwing is occupied by the black border. Both sexes have small white subapical spots. The under surface is white with irregular dark markings. The ♀ has more and darker markings.

D. virgo Bates (29d), from Guatemala and Chiriqui, has black upper surface with white markings; *virgo* in the ♂ the scent-spot occupies the whole posterior half of the hindwing and is shiny grey-white; the ♀ has on the hindwing a broad white median band. — **lubina** Btlr., from Costa Rica, is distinguished by the white *lubina* median spot being divided by black veins. — **lunina** Btlr., from Costa Rica, differs in the ♀ from *virgo* in that *lunina* the upperside of the hindwing is greenish at the inner margin.

D. lua Hew. (29d, e), from Colombia, Ecuador and Peru, has very narrow forewing and broad hind-*lua* wing. Upper surface black-brown with yellow spots, anterior half of the hindwing in the ♂ white-yellow. ♀ with yellow bands and spots on the forewing and yellow hindwing broadly margined with black-brown. Under surface yellow with blackish bands on the hindwing, the ♀ on the forewing also with subapical and median black band.

D. lycosura Hew., from Peru, has almost black forewing with a large light yellow spot in the middle *lycosura* and two small subapical yellow spots, hindwing grey-black with almost white scent-patch on the anterior part. Under surface grey-black with large yellow spots in the middle of the hindwing and some red spots at its base, at the costal margin of the forewing three small yellow spots. Only known to me from the figure.

D. leonora Hew. (29e), from Ecuador, has a smaller yellow spot in the middle of the hindmargin *leonora* of the forewing than *lycosura*, but also several small yellow spots. The hindwing is black-grey, on the grey-white, silky scent-patch (friction-area) of the hindwing is placed a rather sharply defined yellow scent-scale-spot, the inner margin of the hindwing is broadly grey-blue. The ♀ is very different: white with broad black margins, a black band in the cell of the forewing and three small white subapical spots. Under surface pearl-white with yellow interneural stripes in the ♂, whilst the ♀ has blackish markings which correspond more to those of the upperside.

D. niepelti Weym., which forms a transition to *lewyi*, differs from it in that the wedge-spot behind the middle of the costa in the ♂ is reduced to a streak and the whitish inner-marginal spot of the forewing is so much enlarged that it extends beyond the median into the cell; from Ecuador.

D. lewyi Luc. (= *nasua* Fldr., ♀ *kadenii* Fldr.) (29e), from Venezuela, Colombia and Ecuador, has *lewyi* black upper surface with subapical and postmedial yellow spots as well as whitish stripes at the inner margin of the forewing. The hindwing is black-brown, the scent-scale-patch is yellowish, the broad yellow inner margin is divided into spots by the black veins. The ♀ is yellowish white with broad black margins. Under surface pearl-white with yellow markings on the posterior and brownish markings on the anterior part of the hindwing. In the ♀ these markings are black-brown, also the forewing has black-brown subapical markings and black-brown markings in the cell. — **boliviensis** Stgr. i. l., from Bolivia and Peru, has larger subapical *boliviensis* and postmedial yellow spots on the forewing, but the light stripe at its inner margin is absent; the yellow markings on the posterior part of the hindwing are somewhat lighter.

D. schausii Dogn., from Ecuador (Loja), has a similar female to that of *lewyi*. Upper surface black-*schausii* grey with three white subapical spots and a small white spot at the costal margin at the discocellular, basal part of the forewing white, upper surface of the hindwing black-grey, anterior part bluish white, under surface of the forewing similar to the upper, but the subapical spots light yellow, hindwing black with yellow costal margin, a small yellow stripe in the cell and three red basal spots.

D. critomedia Hbn. (= *crisia* Fldr.) (29e, f), from Venezuela, Colombia and Brazil (?), has on the *critomedia* black forewing a strongly curved broad white median band, which in the ♀ is divided by a broad black stripe. The hindwing is white with black margins. Under surface white with dark markings.

euryope. **D. euryope** Luc. (29f), from Mexico, is above black with yellowish white median band on the forewing. The large friction-spot of the hindwing is light bluish, the scent-scale-spot on it white, from the inner margin to the middle of the hindwing runs a yellow band, divided into spots by the black veins. Only known to me from the figure.

ines. **D. ines** spec. nov. (29f), from Ecuador, is a good deal like *euryope*. The median band is much narrower and snow-white, at the inner margin of the forewing there is a small yellow scale-stripe. The ♀ has sulphur-yellow hindwing, broadly margined with black-brown. The underside has dull gloss, is grey-black and has white spots.

lygdamis. **D. lygdamis** Hew. (29f), from Ecuador, has black upper surface with bluish markings. The under surface is much more like that of a *Catantistris* than a *Dismorphia*. Only known to me from the figure.

hyposticta. **D. hyposticta** Fldr., from Venezuela and Colombia, has in the female yellow upper surface with broad black-brown distal margin, interrupted median band and 3—4 small white subapical spots on the forewing, the yellow ground-colour of the hindwing makes a tooth into the dark distal margin between the 3. median vein and the lower radial. Under surface of the forewing similar to the upper, paler, with yellow marginal spots, hindwing black-brown with a number of large yellow spots. Only known to me from the description.

hippotas. **D. hippotas** Hew. (29g), from Ecuador, has black-brown upper surface with white spots. The ♀ is very similar to the ♂. Under surface impure white with yellowish spots of scales. The ♀ has also black markings on the forewing.

teresa. **D. teresa** Hew. (= *praxidice* Hew.) (29g), from Ecuador, has black-blue, somewhat glossy upper surface with white spots. The ♂ has besides the clay-yellow scent-spot at the costal margin of the hindwing a large „brand“ on the upper surface in the middle of the forewing. The ♀ is very similar to the ♂. Underside similar to that of *hippotas*.

praxidice. **D. praxidice** Hew., from Ecuador, has more rounded forewing than *teresa*, somewhat darker under surface, otherwise no constant differences.

nemesis. **D. nemesis** Latr. (= *atthis* Dbl.) (29g), from Mexico, Venezuela, Colombia, Ecuador, Peru, etc., has the upper surface of the forewing dark brown with small yellow spots, the anterior half of the hindwing (scent-area) is shiny grey, the posterior part yellow. The ♀ is very different: white or yellowish with black markings, the hindwing has only a narrow black distal margin. The under surface is grey with lighter and yellow spots. — **D. viridifascia** Bltr., from Costa Rica, has smaller, linear yellow spots and on the hindwing a light greenish band. ♀ with light brown margin.

cinerascens. **D. cinerascens** Salv. (29g, 30a), from Costa Rica and Chiriqui, is black above and has on the forewing white spots and on the hindwing a grey-blue, wedge-shaped band before the black distal margin. The ♀ has black hindwing with a broad white median band. The under surface is similar to that of *nemesis*.

melia. **D. melia** Godt. (30a), from Brazil (Santa Catharina and São Paulo), has the forewing black above with yellow markings and the hindwing yellow with black markings. The ♀ is a so-called *Acraea*-mimic, rather similar to *Acraea* (*Actinote*) *thalia* and resp. *anteas*; this (Brazilian) form is **acraeoides** Hew. (30a), the other form. **mimetica** Stgr., from Cayenne, has more yellow ground-colour, but does not differ in the markings.

larunda. **D. larunda** Hew. (30a), from Ecuador, is a mimic of *Heliconius*. Upper surface black with yellow median band and yellow submarginal spots as well as large red basal spot on the forewing and similarly marked hindwing. The proximal part of the hindwing is beneath red, the broad black border has small white spots and at the distal margin there is a yellow submarginal band.

spio. **D. spio** Godt. (30a), from the Antilles, has the forewing sharply falcate in both sexes. In the ♀ the yellow-red markings of the ♂ are sulphur-yellow.

cubana. **D. cubana** H.-Sch. (30b), from Cuba, has the forewing only moderately pointed and resembles *spio* in markings and colouring.

lysianax. **D. lysianax** Hew. (30b), from the Upper Amazon, has the forewing completely rounded. Only the ♀ is known, which differs from the ♂ of *cubana* by the absence of the yellow subapical spots and further in that the yellow median band is extended to the base in a narrow stripe at the costal margin.

tricolor. **D. tricolor** S. & K. (30b) resembles *Heliconius vicinus* Mén. Only the ♀ is known. Upper surface black, forewing with a broad yellow median band and red inner-marginal stripe, hindwing with red median band and a yellow-red submarginal spot at the distal margin. Under surface similar, but the red on the hindwing reduced to small stripes, and white submarginal spots. Habitat still unknown.

amphione. **D. amphione** Cr. (30b, c), from Guiana, bears a superficial resemblance to certain forms of *Heliconius*. — **D. arsinoe** Fldr., from Colombia, differs in the larger and snow-white scent-scale-area on the hindwing; the inner margin of the forewing is red-brown and between submedian and median there is a small black stripe in the red-brown. — In **astynomides** Stgr. i. l., from Venezuela, this black stripe is absent and the inner

margin itself is very narrowly brown-red and the hindwing only differs from that of *arsinoe* by the red-brown inner margin. — **arsinoides** Stgr., from Chiriqui, has the hindwing as in *astynomides*, but the yellow spots of the central row are smaller and widely separated and the inner margin of the forewing is broadly black. — **praxinoe** Dbl., from Mexico, differs from *arsinoides* in that the white scent-scale-area of the hindwing throws out some teeth into the black distal margin and the colour of the red-brown markings is lighter. — **discrepans** Btlr. (30c), from Colombia and Ecuador, has only very small yellow spots instead of the yellow median band. — **meridionalis** form. nov., from Bolivia, has only two yellow subapical spots on the forewing and a yellow median band, interrupted in the middle but broad, which does not touch the reduced red-brown markings. — **amphithea** Fldr., from Mexico, is larger than *amphione* and has larger and broader, more falcate forewing. Unknown to me, probably not different from *praxinoe*. — **egaena** Bates, from Ega, is in the female very dark red-brown, has much yellow central and subapical marking and is very similar to *Mechanitis polymnia egaensis* Bates. — **rhomboidea** Btlr., from Nanta (probably East Peru) (or Nauta, Upper Amazon?), is the largest form. In it the yellow subapical spots are entirely absent, the red-brown markings are much developed and in the posterior part of the forewing reach the distal margin, the yellow median band is only represented by some small spots at the costal margin. The ♀ has red-brown hindwing with black wedge-shaped marginal spots, the yellow median band is very broad and almost reaches the inner angle. Is perhaps a separate species. Only known to me from the figure.

D. laia Godt. Shape and size as *amphione*. Forewing black with 3 red-brown spots: a long one in the cell, another at the inner margin, and the third, a small round one, is placed towards the middle of the wing and sometimes united with the first; in addition the distal half of the wing is distinguished by a band-like spot, divided by the veins. Upper surface of the hindwing broadly glossy white along the costal margin, then red-brown with black, dentate, rather broad margin. Under surface of the forewing glossy white, margined with yellow at the apex, the other markings as above, but larger, under surface of the hindwing brownish with several lighter patches, the apex margined with red, a row of rather large yellow marginal spots and 2 small spots of the same colour near the distal margin (at the distal angle). Surinam, Cayenne. Only known to me from the description.

D. astynome Dalm. (= *polymela* Hbn.) (30c), from Brazil (Santa Catharina), is very similar to *amphione*, but most probably a separate species. Instead of a row of yellow subapical spots *astynome* has only one such spot, occasionally with a dot before it, and this is placed nearer to the apex than the row of spots in *amphione*. The inner margin of the forewing is always broadly black. The under surface is essentially different. — **astyocha** Hbn., from Rio Grande do Sul and São Paulo, differs in the yellow apical spot of the forewing being placed directly at the margin and the under surface being lighter and less marked.

D. dejone Hew. (30c), from Central America, has the forewing black above with white spots, the anterior half of the hindwing (scent-spot) light grey, shiny, posterior part of the hindwing red-brown with black margin. Under surface of the hindwing grey-brown with a transverse row of yellow spots in the middle and a few other yellow spots and dots. ♀ unknown to me.

D. sororna Btlr. (30d), from Costa Rica and Chiriqui, is a large species. The ♂ has black forewing with yellowish apical, subapical and central spots, the larger anterior part of the hindwing (scent-spot) is light grey, with silky gloss, the posterior part is red-brown, margined with black. The ♀ resembles the *Lycorea*-species; it has black forewing with the same rows of spots as the ♂, in addition a red-brown transverse band on the proximal half of the forewing, the hindwing is red-brown with black distal margin and some small yellow marginal spots. The under surface resembles the upper. — **hagaresa** Btlr., from Costa Rica, is probably nothing more than a less marked form of *sororna* (seasonal form?).

D. cordillera Fldr. (30d), from Colombia and Chiriqui, though specifically separated by BUTLER from *sororna*, appears really to belong to it as a seasonal form. The yellow spots of the forewing are larger, in the ♂ the posterior part of the hindwing is yellow and the ♀ also has lighter markings, hence the hindwing is almost yellow. The under surface resembles the upper in markings and colouring.

D. orise Bdv. (30e), from Guiana and Bolivia, but probably also occurring elsewhere, is very similar to *Thyridia psidii* L. and *confusa* Btlr., especially in the female. The perfectly transparent wings have black margin and black median band, which, however, in the ♂ only reaches the middle of the wing on account of the scent-scale on the anterior half of the hindwing.

D. rhetes Hew., from Colombia, differs from **hewitsoni** Kirby (30e, f), from Ecuador, only in the light spots on the distal part of the forewing and on the hindwing being white (glassy), not bluish. This species bears a general resemblance to several of the larger Ithomiids.

D. theonoe Hew. (30e), from Ecuador, is very similar to *Ithomia flora* Cr. It is transparent and has black margins and markings. — **melanoe** Bates, from the Upper Amazon, has broader black margins and bands; it is regarded by BATES as a mimic of *Ithomia onega* Hew.

D. siloe Hew. (30e), from Colombia, has the posterior half of the hindwing red-brown. It has the general aspect of an Ithomiid, but is not specially like any particular species.

- theucharila*. **D. theucharila** Dbl. (30f), from Venezuela, also shows a general resemblance to an Ithomiid. The ♀ has the hindwing entirely brown with black markings and broad yellow basal band to the forewing. — **nella** Btlr., from Colombia, is not different except that the spots of the middle row are not yellow but transparent white.
- lysinoe*. **D. lysinoe** Hew. (30d), from the Upper Amazon, is similar to *siloe*, but has in the male only a broad yellow marginal band, which is bordered anteriorly by a black band.
- lysinooides*. **D. lysinooides** Stgr. (30f), from West Colombia (Cauca Valley), is only known in the female. It is very similar to *lysinoe*, but has on the underside of the hindwing a complete row of white marginal spots.
- erythro*. **D. erythro** Bates (30f), from the Amazons (S. Paulo de Olivença), is rather similar to *Hypoleria aureliana*, *aureola*, etc. It is rather variable, the red-yellow apical spot being sometimes divided into several spots, sometimes there is also a red-yellow spot near the inner angle.
- batesi*. **D. batesi** spec. nov. (= *lysinoe* var. *Hew.*) (30f), from the Amazons, has not only very much red-yellow marking on the forewing but also a very broad red-yellow band on the hindwing. The transparent parts of the wings are bluish.
- leuconoe*. **D. leuconoe** Bates, from the Amazon River (S. Paulo de Olivença), has a larger red-yellow subapical spot and yellowish subapical band on the hindwing. The latter is entirely absent in **melanoides** form. nov. (30f, g), from Ecuador (Coca), which also has smaller transparent spots on the forewing and somewhat broader black distal margin to the hindwing. This species is very similar to *Ithomia ida* and *ilerdina*.
- fortunata*. **D. fortunata** Luc. (30g), distributed from Mexico to Chiriqui, has a general Ithomiid-habitus, but without special resemblance to any particular species. The transparent wings have black margins and bands. The ♀ has a whitish transparent subapical band, the ♂ in its place some entirely glassy spots. — Whether **ithomiella** form. nov. (30g), from Ecuador (Balzabamba), is a form of *fortunata* or a separate species I am unable to judge for want of sufficient material. The ♂ differs from *fortunata*-♂ in that the glassy median spot of the forewing is broader but shorter and behind it there is another small glassy spot. The ♀ is very different from *fortunata*-♀, as may be seen from the figure. Beneath the ♂ has larger white marginal spots, also the ♀ has complete rows of larger and rounder white marginal spots, whilst the ♀ of *fortunata* has only 3 white dots on the apex of the forewing.
- antherize*. **D. antherize** Hew. (29h), from Mexico, is in the male similar to the *fortunata*-♀, it has no light markings on the distal part of the forewing except a broad white subapical band. On the underside of the hindwing there is a large white apical spot. — In **argochloe** Bates, from Ega, the margins of the white band of the forewing are sinuous, the hindwing is darker and has a submarginal narrow light band.
- avonia*. **D. avonia** Hew. (29h), from Ecuador (Quito and Balzabamba), has semitransparent yellow markings, whilst **pallida** form. nov. (seasonal form?), from Ecuador (Paramba and Chimbo), has much lighter, glossy markings, entirely white in the distal part of the wing. The under surface is similar to the upper, but both wings bear at the distal margin a row of white spots.
- pinthaeus*. **D. pinthaeus** L. (= *eumelia* Cr., *vocula* Cr.) (29h), from Guiana, the Amazons, etc., has yellow upper surface with black markings; in the ♀ there is also a black stripe at the costal margin of the hindwing. The under surface is similar to the upper, but has small white marginal spots and on the hindwing a red-brown submarginal band. The species somewhat resembles the Ithomiid-genus *Aeria* Hbn. — **amelina** Hopff. (29h), from Peru, has narrower black bands and consequently larger yellow areas, also the red-brown marginal band on the underside of the hindwing is narrower. — **ela** Hew., from Ecuador, has in addition small yellowish submarginal spots at the inner margin of the hindwing and the submarginal band of the hindwing is yellow instead of red-brown.
- ithomia*. **D. ithomia** Hew. (29h), from Ecuador, is similar to *pinthaeus*, but by the division of the postmedian yellow band 4 yellow spots are formed on the forewing, also the distal margin of both wings has a complete row of white spots.
- methymna*. **D. methymna** Godt. (30g), from Brazil (Minas Geraes), is above an exact copy of *Heterosais gazoria* Godt. (36d), which flies together with it. Beneath the two species differ in that *methymna* has white marginal spots on both wings and on the hindwing an indistinct red-brown submarginal band.

36. Genus: **Styx** Stgr.

As already said, the systematic position of this peculiar genus is altogether uncertain. The idea that *Styx infernalis* might be the ♀ of an Erycinid is however incorrect, since the ♂ of *infernalis* is also known. The external appearance of this insect is Pierid-like, similar to *Davidina alticola*, which is figured in vol. I, pl. 19b. The neurulation of the forewing shows no striking differences, on the other hand that of the costal margin of the hindwing is not unlike certain Ithomiids. In the structure of the palpi and legs the genus shows great similarity to the Erycinids.

- infernalis*. **S. infernalis** Stgr. (30g), from south-eastern Peru (Chanchamayo), is in both sexes transparent grey-black with lighter central part of the wings. Only a few specimens of this species are known, so that it would seem to be very rare or only to occur in a few restricted localities.

Additions and Corrections.

p. 57: read *eronima* instead of *eronina*.

Pieris elodia forma **deserta** *Fruhst.*, from Ecuador, has on the underside the apex to the forewing *deserta* pale straw-coloured and the same colour on the upper surface of the hindwing.

p. 60: *eleusis* belongs to the genus *Leptophobia*. When I worked out the genera *Pieris* and *Leptophobia* I knew *eleusis* only from the description.

p. 62.: **Leptophobia gonzaga** *Fruhst.*, from Ecuador (Papalacta), captured by R. HAENSCH in the middle of January, is somewhat larger than *eleone*, hindwing more elliptical, ground-colour white, forewing similar to that of *pinara*, the costal more extended brown-green, the anal margin powdered with blackish almost to the middle of the wing. The black distal border of the forewing likewise extending at the hindmargin proximally to the middle of the wing, otherwise almost of the same outline as in *pinara*, especially in the proximal, median incision. At the apex of the cell of the forewing the black band is absent. Hindwing with black diffuse basal area; distal margin yellowish with some black dots at the extremities of the veins. Under surface: forewing whitish; distal border, as far as the black margin of the upperside shows through, suffused with dull yellowish. Hindwing yellowish white, slightly glossy, with small black triangular spot at the end of the cell and yellowish basal area. ♀, upper surface: forewing broadly margined all round with brown-black, so that the white ground-colour is reduced to a mushroom-shaped discal patch. Hindwing yellowish, costal and anal region defined by a thin black line; the central area bearing 2 black dots. Under surface as in the ♂. Fringes in both sexes yellowish. Only known to me from the description.

Lept. eleusis molitica *Fruhst.*, from Peru (Huancabamba), has a more pointed forewing and rounder hindwing than *helena*. Upper surface purer white, in the wet-season form distinctly more broadly margined with black than in *helena*. Costal part of the forewing darker, more yellow instead of white. The dry-season form appears to have a narrower border than the dry-season form of *helena*, but of a deeper black.

p. 64: *Perrh. pyrrha alethina* *Btlr.*, from Costa Rica, is in the female similar to the *malenka*-♀; the *alethina*. subapical spots are absent, the spots of the median band are sharply yellow, the black spots of the anterior band larger and distinct, the black median band of the hindwing is absent. — Aberration?

p. 65: read *antodyca* instead of *autodyca*.

p. 67: *Archon. nigripennis* has a black forewing and a small red spot on the hindwing; *hades* *Fruhst.* appears to be synonymous with it. — In *rosacea* the three white spots on the forewing are small and well separated, the hindwing has two deep rose-red oval spots. — *approximata* has the rose-red spot on the hindwing nearer to the distal margin, it is broader, uniform in colour, and divided by three veins. The yellow spot on the under surface is much smaller. Found in the Polochic Valley.

p. 68: **Appias peregrina** *form. nov.* (26 c), from Cuba, I consider a form of *janeira* *Bönnigh.* The *peregrina*. latter I formerly regarded as an aberrant form of *drusilla* because the author said nothing about the very different shape. It is not necessary here to describe the shape, as it can be seen from the figure. I have before me two ♂♂ of *peregrina*; in these the upper surface is not glossy white, but strongly yellow, particularly on the hindwing, the proximal part of the costal margin of the forewing is more strongly blackened than in *drusilla* and the black border of the forewing is not extended to the inner angle, but scarcely to the 1. median vein. On the underside the basal half of the cell of the forewing is yellow and the hindwing has a subanal yellowish stripe from the base to the distal margin. — The existence of two American species of *Appias* is consequently established.

p. 71: read *teutamis* (= *epimene* *Heu.*) instead of *teutanis*. The ♀ is black above and has on the forewing a broad red median band, which gives it a resemblance to the red-banded species of *Heliconius*. Instead of *troezene* *Fldr.* read **affinis** *Röb. spec. nov.* (22 d). — *Catasticta troezene* *Fldr.*, from Colombia, is above yellow, similar to *eximia* (22 g), but the wings are smooth-margined, the yellow median markings are broader and more narrowed anteriorly, in the cell is a comma-shaped yellow spot, hindwing with much broader and not dentate black marginal markings. Under surface similar to *tomiris*, but the white central markings of the forewing are twice as broad and the dark central markings of the hindwing much broader and pointed distally at the veins.

p. 72: **Catasticta incerta** *Dogn.*, from Ecuador (Loja), is not really identical with *manco*; it is, if not a separate species, at least a good local form of *manco*. The upper surface is yellower, has much less black marking and large white marginal spots. The ground-colour of the underside of the forewing is much yellower, instead of the small grey triangular marginal spots in *manco* there are round resp. square yellow spots in *incerta*, the hindwing has more black marking and deeper yellow spots.

p. 74: **Catasticta poujadei** *Dogn.*, from Ecuador (Loja), is very similar to *clara* (22 g), but smaller, the upper surface of the hindwing is almost the same, but the forewing has larger yellow spots, some of which

are crescent-shaped, and the white, streak-like apical spots are absent, the black distal margin is narrower. In the shape of the wings it agrees more with *eximia* (22 g).

jaliscana. p. 78: In **Hesperocharis jaliscana** *Schaus*, from Mexico (Guadalajara), the ♂ is white, the ♀ lemon-coloured, both with black apical and distal-marginal markings as far as the third median vein. Hindwing beneath of a beautiful yellow with a red spot at the base, a black spot behind the cell and a row of smoky grey angular spots at the costal margin and apex. Similar to *Hesp. crocea*.

graphites. **Hesperocharis graphites** *Bates*, from Guatemala, is large, yellow with black marginal markings and less sharply black submarginal ones, black median spot on the forewing; under surface with much broken black markings and ochre-yellow cell on the forewing.

paranensis. **Hesperocharis paranensis** *Schaus*, from Parana (Castro), is white with slight greenish tint, distal half of the costal margin narrowly black, small triangular black spots in the apex and at the distal margin of the forewing. Under surface of the forewing whitish, apex and costal margin yellowish, a black dot at the base, antemedian, median and postmedian irregular and angulated black lines, which are interrupted by the veins, small black spots at the distal margin between the veins. A small species.

crocea. **Hesperoch. (?) crocea** *Bates*, from Costa Rica and Mexico, is above sulphur-yellow in the ♂, deep canary-yellow in the ♀, in both sexes slightly dark marked at the apex of the forewing. The under surface is ochre-yellow with the exception of the lighter posterior part of the forewing and has two blackish spots at the costal margin of the hindwing and a similar spot at the point of origin of the 1. median vein. — Apart from the very different facies, which agrees well with *idiotica* *Btlr.*, *crocea* also differs somewhat from *Hesperocharis* in neuration, since the upper discocellular of the forewing is absent in the ♂ and very small in the ♀ and the other two discocellulars of the forewing are of very unequal length (lower discocellular longer). It appears to me now, since I have examined specimens which are very probably congeneric with *idiotica*, that the genus *Heliochroma* *Btlr.* is justified. In shape the species of this genus are very similar to *Daptonoura*, though the hindwing is more elongated at the inner angle, whilst in neuration they more nearly approach *Hesperocharis*.

sinoides. p. 81: **Terias sinoides** *Capr.*, from Rio de Janeiro (Itaipu), is probably a small form of *phiale*. Upper surface white, slightly yellowish, black distal margin of the forewing shorter and narrower than in *phiale*. Hindwing without markings. Under surface with the exception of the posterior part of the forewing more strongly yellow than the upper, in the middle of the hindwing some small blackish spots.

portoricensis. **Terias citrina portoricensis** *Dew.*, from Porto Rico, is smaller and lighter than the Cuban form, the violet spots on the under surface are more flesh-coloured.

nigrocincta. **Terias nigrocincta** *Dogn.*, from Ecuador (Loja), is similar to *plataea*, but has a lighter forewing and the hindwing of the same colour. The black border of the inner margin of the forewing is joined to the border of the distal margin, the orange-yellow stripes at the inner margin are absent. The hindwing has large, proximally pointed, well separated black marginal spots. The yellowish under surface has on the hindwing brownish spots and dark scales.

ribbei. **Dismorphia ribbei** *Godm. & Salv.*, from Panama, is similar to *fortunata*, but the subapical band of the forewing is divided and there is a small white apical spot. — Is it a separate species?

3. Family: **Danaidae**.

Particulars as to the characters of this family are given in the Palaearctic part of this work (vol. I, p. 75). The Danaids are distinguished from the Pierids especially by the aborted forelegs; from the Heliconines, Nymphalids and Satyrids by the basally bifurcate submedian of the forewing. The antennae are thin, without distinct club. Cell of the hindwing long and closed. In America the true Danaids are only represented by a few species of the genus *Danais*, which belong to the subgroup *Anosia* and are mostly met with in a large number of individuals in wooded country (especially in North America). In South America on the contrary an externally very different subfamily, the *Ithomiinae*, is developed in numerous genera and hundreds of species, which are commonest at the tributaries of the Upper Amazon, in the valleys of the Andes, but occur singly as far as Argentina and North America. A third small group, the *Lycoreinae*, forms the transition between the two before-mentioned subfamilies and combines characters of both. Its representatives are most numerous in the central part of America.

1. Subfamily: **Danainae**.

Wings broad, abdomen short. The scent-organ of the ♂♂ consists of scale-like structures or pouches on the hindwing. The forelegs of the ♀♀ are short, clubbed at the end.

1. Genus: **Danais** Latr.

Powerful, mostly yellow-brown butterflies with dark margins and whitish dots. They have a long-sustained flight and are fond of the open country, accompanying cultivation further and further into the primeval forests as soon as a few clearings have been formed where the foodplants of the larvae, species of *Asclepias*, can get a foothold. The larvae are bright-coloured, with transverse stripes, and provided with soft appendages. Pupae bell-shaped, with gold ridges or dots.

A. **Archippus** Group.

Larvae with 2 pairs of fleshy appendages. Cell of the hindwing long. ♂ with moderately small scent-spot.

D. archippus F. (= *plexippus* L.) (vol. I, pl. 28c). Body black-brown, hairy, with whitish dots *archippus*. and streaks. Wings above brown-yellow with dark veins and margins; at the distal margin a double row of small whitish spots. Above the end of the cell of the forewing a black-brown patch with several brownish whitish spots. On the under surface the hindwing is yellowish, the veins with broader edges and the white marginal spots larger. — From Nicaragua southwards occurs a local race which I call **nigrippus** *form. nov.* In this the *nigrippus*. whole apex of the forewing as far as the end of the cell is black-brown and the spots are pure white. This form especially is found also in the north of South America. — HULST designates as **fumosus** a form of *archippus* with *fumosus*. dark black-brown ground-colour. — Larva yellowish with black transverse stripes and has on the 3. and on the 11. segment 1 pair of fleshy appendages. It lives on *Asclepias curassavica* and requires about 3 weeks for its development. It is protected by its pungent, nauseous smell. Pupa light green, transparent, with golden dots. In North America *archippus* has as many as four broods. The butterflies of the first appear at the end of May. Sometimes they occur in large swarms. In America the species is found from Canada to Paraguay. The typical northern form, however, extends southwards only to Central America.

D. erippus Cr. (31a) is very nearly allied to *archippus*, but always differs from it by the absence of *erippus*. the black-brown inner margin of the forewing. Moreover the veins on the under surface of the hindwing are broadly margined with white. Larva yellowish with black head and transverse stripes. On the 2. and 11. segments 2 appendages each; the anterior ones are used as antennae. Pupa berry-shaped, thickest at segment 6, transparent white-green with shiny gold dots. The habitat of *erippus* is Brazil from whence it has spread southwards to Patagonia (Berg) and northwards to Central America and the West Indian islands.

D. cleophile Godt. The smallest American species; it differs from all the other forms in having the mar- *cleophile*. ginal and apical spots yellowish instead of white. The apex of the forewing is broadly black. This rare and beautiful species occurs only on the West Indian islands, particularly Haiti, Cuba and Jamaica.

B. **Gilippus** Group.

Larvae with 3 pairs of fleshy appendages. Cell of the hindwing short. ♂ with moderately large scent-spot.

D. gilippus Cr. (= *vincetoxici* Hbn., *manuja* Ersch.) (31a). Similar to *erippus*, but smaller and with- *gilippus*. out the black transverse band in the apex of the forewing. Between the median veins of the forewing inside the black margin 4 additional larger, white spots. Further a number of white spots are placed at the end of the cell of the hindwing. Veins in the disc of the hindwing beneath only narrowly edged with white. Abdomen brownish. South America, especially at the coast near Rio de Janeiro, but also in Bolivia. — **nivosus** Godm. *nivosus*.

& *Salv.* (= *hermippus* *Druce*), a form of *gilippus*, has much paler ground-colour and very large white spots; especially at the apex of the cell of the hindwing; it inhabits northern Peru.

plexaure. **D. plexaure** *Godt.* This small species is very similar to *gilippus*; but the inner row of white spots, between the median veins of the forewing, is always larger, especially on the under surface. Moreover *plexaure* has on the hindwing another row of white spots between the black distal margin and the apex of the cell. Further the under surface of the hindwing in *plexaure* is always grey-brown, different from that of the forewing, whilst in *gilippus* it is red-brown; *plexaure* occurs in southern Brazil and in Argentina. Larva on *Aselepias curassavica*; very similar to that of *erippus*, but with another pair of false thorns on segment 5. The markings also similar to those of *erippus*; the black is so much extended that the light ground-colour is almost entirely suppressed except for 2 vivid yellow transverse bands. False thorns black, bright red at the base. Pupa likewise similar to that of *erippus*.

berenice. **D. berenice** *Cr.* (= *erippus* *F.*, *gilippus* *Smith*) (31a) is the same size as *gilippus*. Dark brown, the veins little prominent. The white spots of the forewing are small; on the under surface of the hindwing they are almost entirely absent. Veins on the underside of the hindwing more broadly margined with white on the disc. The double row of small white marginal spots is usually incomplete. From the south of the United States and *strigosa.* the West Indies to South Brazil. **BATES** describes as *strigosa* a form from Guatemala of somewhat lighter colouring, in which the veins, especially on the upperside of the hindwing, are dusted with grey. This form also occurs in Mexico and Texas. — ab. *thersippus* *Bat.*, from Panama, is according to **GODMAN** and **SALVIN** an un-*hermippus.* usual form of *berenice*. It has dull, dark reddish brown ground-colour and dark brown distal margins. — **hermippus** *Fldr.* (31a) approaches *berenice*, but is easy to recognise by the strikingly light, grey-brown colour and strongly grey-white dusting in the disc. It has also particularly large white spots on the forewing. It inhabits Colombia. — Larva of *berenice* on *Aselepias curassavica* and *amplexicaulis*. It is whitish violet with red-brown transverse stripes and violet incisions, as well as a yellow lateral line. On segment 2, 5 and 11 is placed 1 pair of appendages. Pupa greenish with black-yellow transverse line on the venter and golden dots. It is more elongate than in *archippus* without the sharp ventral ridge. The butterflies appear in June. They fly in large numbers in sunny places up to a height of 6000 ft.

jamaicensis. **D. jamaicensis** *Bat.* Markings as in *berenice*. Colouring pale yellow-brown with brown margins. The veins of the hindwing margined with grey as in *strigosa*. Smaller than *berenice*. It was once brought in large numbers from Jamaica. Larva with transverse black and white stripes, dorsally with a short yellow band on each segment and yellow spots at the ends of the white stripes above the legs. On segment 5, 6 and 11 is placed 1 pair of red appendages, the first pair the longest. The pupa is light green with very small black dots and golden spots.

eresimus. **D. eresimus** *Cr.* (31b). Differs from all the preceding in the relatively small cell of the hindwing, as well as in the absence of the black and white margins on the underside of the hindwing. On the other hand it has here near the dark brown distal margin a lighter broad band and between this and the apex of the cell a second, undulate band, joined to the first at the ends. The colour of the upper surface is brownish, at the base of both wings darker and at the distal margin black-brown. The black-brown costal margin of the forewing is widened behind the apex of the cell into a triangle, the apex of which touches the opposite distal margin, as in *erippus*; the white marginal and apical spots are likewise present. The abdomen is the same colour as the wings. **CRAMER** described the species from Surinam; but it also occurs in other parts of northern South America; thus in Colombia, Peru and on the Amazons, though nowhere very common. Is fond of visiting *xanthippus.* the banks of rivers. — **xanthippus** *Fldr.*, from Brazil, is said to be most nearly allied to the preceding and to differ from it by lighter colouring, whilst the blackish distal margin of the hindwing is broader and the light spots *erginus.* on its under surface are absent. — **erginus** *Godm.* & *Salv.* This form is likewise said to approach *eresimus* and to be distinguished from it by the darker colour of the wings and more distinct white spots. The apex of the forewing is almost black and the disc of the hindwing appreciably lighter. The habitat is northern Peru.

cleothera. **D. cleothera** *Godt.* (31b). Very nearly allied to *eresimus*, but differs especially in the under surface of the hindwing, the blackish veins of which, as in most other species, are margined with white. On the other hand *cleothera* has also the two lighter bands there as in *eresimus*, and indeed the inner one is still darker and therefore more distinct. The black costal margin is only widened as far as to the discocellular. The hindwing has mostly a double row of white marginal spots on the upper surface. **GODART** gives (erroneously) the island of Timor as locality of *cleothera*; it occurs in Mexico, Central America and on the Antilles; according to **DOUBLEDAY** also in Venezuela.

2. Subfamily; **Lycoreïnae.**

Wings elongate. Abdomen extending beyond the anal angle of the hindwing; posteriorly thickened like a club. Antennae reaching to the end of the cell. Claws with appendages. ♂ with 2 retractile tufts of hair at the extremity of the abdomen. The species of the two genera which belong here are confined to the

Neotropical region. They occur in open localities in the primeval forest. Their flight is irregular. The larvae are similar to those of the *Danainae*; they are said to live on *Solaneae*.

2. Genus: **Lycorea** Dbl. & Hew.

Large, stately, bright-coloured butterflies, mostly of yellow-brown ground-colour, with blackish margins and streaks, as well as yellowish bands and spots and also white marginal dots. The species have all the same scheme of markings, which is also repeated in many genera of the *Ithomiinae*, and of which I will therefore here give a general description, afterwards referring to it for short as „*Lycorea-habitus*“. The figure of *Lycorea halia* Hbn. on pl. 31c may serve as an example. The ground-colour is mostly a peculiar reddish yellow-brown. The apical half of the forewing is black-brown with an oblique band formed of yellow spots, which crosses the apex of the cell, and with one or several yellow subapical spots. From the black-brown apical part 3 streak-like projections run towards the base: one along the median, the others along the costal and hindmargin. On the disc of the hindwing there is an oblong, band-like, blackish loop, open towards the base, from the costal margin towards the apex and then back to the inner margin. The oblong space enclosed by this loop is often yellow in a number of species from certain districts. The distal margin of the hindwing is black-brown and mostly has above and beneath a row of white submarginal dots. This scheme of colouring can be recognised again in most *Lycoreas* and many *Ithomiids*, though the pattern is often somewhat altered, the yellow being replaced by brown or the black sometimes covering almost the whole hindwing.

The *Lycoreas* are feeble fliers, prefer the edges of the roads and open places and are fond of visiting flowering shrubs, where, as they hang on the flowers, they can scarcely be distinguished from the similar *Melinæa* and *Mechanitis*.

Unfortunately very little is yet known as to the larvae. BOISDUVAL mentions that they have flexible fleshy appendages, which are arranged in pairs on some of the segments, also that they are similar to those of the true Danaids and likewise live on *Asclepiadeae*. According to GUPPY some at least of them are similar to those of *Tithorea*, with only 1 pair of appendages on segment 2 and live also on cacao and on a plant similar to caoutchouc.

L. eva F. Markings as in the figured form *concolor* (31 c), but the forewing has on the discocellular *eva*. the typical yellow oblique band, which at the costal margin encloses a blackish spot. In *eva* and the allied forms the cell of the hindwing is only short, as the lower and middle discocellulars form only a very obtuse angle. This form occurs in the north-east of South America, especially Guiana. — The figured local form **concolor** Stgr. *concolor*. (31c) differs from the nymotypical form in the absence of the yellow transverse band on the forewing, which also occurs in many *Ithomiids*, e. g. *Hirsutis melanina*, *Melinæa chincha*, *Ceratinia bicolora*, *Mechanitis deceptus*, etc. All these forms occur, like *concolor*, on the eastern slopes of the Andes, in Peru and Ecuador. — **pasinuntia** Cr. *pasinuntia*. This form is differentiated from *eva* in that the dark distal margin is merged together with the posterior half of the band-loop into a large spot, as in the figure of *ceres*. Is found in the same localities as *eva*, and transitions also occur.

L. ceres Cr. (31c) is distinguished from the similar *pasinuntia* by the longer cell of the hindwing. Further *ceres*. the yellow oblique band of the forewing is only half as broad at the costal margin and encloses no black spot there; also the band is not joined to the 4. subapical spot. This form comes chiefly from Guiana. — The variety with typical *Lycorea-habitus* I call **fasciata** form. nov. In it the loop and the distal margin of the hindwing are *fasciata*. separated by the yellow-brown ground-colour, as in *eva*. Appears to occur especially in the north-west of South America. — **demeter** Fldr. is a dark brown local form from Cuba and Haiti. It has a yellow macular oblique *demeter*. band like *halia* and 3—4 yellow subapical spots. A similar dark form of *fasciata* occurs on the Lower Amazon near Manaos. — The larva of *ceres* is according to GUPPY whitish with black head and segments and oblique, approximated hook-shaped spots. On the 2. segment is placed a pair of long, flexible appendages. In the full-grown larva the colour from the 4. segment onward is yellow. The egg is conical, flattened, yellowish, with numerous cell-like depressions. The larva is hatched in about 5 days.

L. cleobaea Godt. (31b). In this species the yellow transverse band of the forewing is broken up into *cleobaea*. 3 spots, sometimes also the disc of the hindwing is yellowish. It was described from the Antilles, but is also abundant in the north-west of South America to Bolivia. — In Central America, especially Honduras, it appears mostly in the form **atergatis** Dbl. & Hew., in which the yellow subapical spots of the forewing are very large, *atergatis*. the 4. being united with the middle spot of the oblique band. — **pales** Fldr., from the Upper Amazon, has very *pales*. small yellow spots and patches in the blackish apical part of the forewing, and the normally yellow spot at the apex of the cell has assumed the yellow-brown ground-colour. — **cinnamomea** Weym. is an interesting rare *cinnamomea* form from the Upper Amazon with mahogany-brown ground-colour. The markings are similar to those of *atergatis*, but the yellow subapical spots of the forewing are very large and extend from the apex to the black spot at the end of the cell, which is somewhat larger than in *eva*. Apparently very similar dark red-brown forms occur both of *eva* and of *atergatis*. The first may be recognised by the short cell of the hindwing and

the very large, yellow subapical spots of the forewing; in the latter the cell is longer, the subapical spots are smaller and the ground-colour is less reddish.

halia. **L. halia** Hbn. (31c). This South Brazilian species differs from all the preceding in having only 3 subapical spots on the forewing and in the yellow longitudinal spot in the disc of the hindwing. This band-like spot is characteristic of many South Brazilian species of Ithomiids and Heliconines, which closely resemble *L. halia*, such as *Hirs. pseudethra* Btl., *Mel. ethra* Godt., *Mech. nessaea* Hbn., *Cerat. euryanassa*, *Heliconius narcaea* Godt., etc., almost all of which fly together with *halia*. — As ab. **referrens** ab. nov. I designate a form in which this band-spot shows the normal yellow-brown ground-colour. — A further form, in which the yellow transverse band of the forewing is broken up into 3 spots, as in *cleobaea*, I call **discreta** form. nov. In this the yellow spot of the hindwing also mostly assumes a brownish shade.

3. Genus: **Ituna** Dbl. & Hew.

Mostly large, imposing butterflies with transparent, dark-margined wings. The forms are all rather closely allied. Cross vein of the hindwing almost straight and erect. ♂ with 2 reversible hair-pencils at the anus, as in *Lycorea*. Superficially the species are very similar to corresponding forms of *Olyras*, *Thyridia*, etc. They are chiefly mountain species. They occur from Central America to South Brazil. The larvae according to BOISDUVAL are similar to those of *Lycorea* in shape and habits.

lamirus. **I. lamirus** Latr. (= completa Stgr.) (31c). In typical specimens the basal third of the forewing is black-brown. But examples commonly occur which have at the base a large semitransparent triangle, which often again is united beyond the median nervure with the spot between the median veins. This form I call ab. **fenestrata** ab. nov. Both forms vary in the extent of the yellow-brown colour at the distal margin of the hindwing, which sometimes spreads over the whole of the disc. They occur on the eastern slopes of the Andes of Colombia and Ecuador. — On the western slopes of the Andes of Ecuador occurs a local form which is markedly distinct by the absence of the yellow-brown colour, and which I call **decolorata** form. nov. The dark band-marking is otherwise similar to that of *fenestrata*, but weaker, especially the dark subapical band of the forewing is wanting. On the other hand the anal angle of the hindwing is much more broadly blackish. — In *albescens*. Central America occurs the *fenestrata*-like form **albescens** Dist. The glassy spots of the forewing are narrow and oblong, and also yellowish brown, especially in the basal half, as is the hindwing except the dark margins and the radial veins. — The pupa of *lamirus* is elongate, with obtuse tip, brownish with longitudinal rows of dark double spots. The butterflies are fond of floating about in open places a few metres above the ground in the sunshine and the ♂♂ drink in the heat of the day at moist places on roads and river banks.

phenarete. **I. phenarete** Dbl. & Hew. (31d), from Peru and Bolivia, is transparently yellowish and closely resembles *decolorata*. The margins and bands are, however, much more sharply defined, the hindwing at the distal margin more sharply dentate, and only the club of the antenna is yellowish. — **lanassa** Godm. & Salv. is a form of *phenarete* with yellow brown inner margin to the forewing and the anal angle of the hindwing of the same colour.

ilione. **I. ilione** Cr. (31d), from South Brazil, is the smallest species of *Ituna*, and very similar to *phenarete*. The yellow club of the antenna is much shorter. The colour of the wings is more vivid yellow, the band over the discocellular of the forewing is broader, and on the under surface the margins and bands are partly edged with white.

3. Subfamily: **Ithomiinae**.

This group, which is also known under the names Neotropids and Mechanitids, is by far the richest in forms of the Danaids in America. It contains over $\frac{9}{10}$ of all the forms and like the *Lycoreinae* is confined to America. Superficially many species recall on the one hand the *Lycoreines* and on the other the *Heliconines*, but are differentiated by the neuration, the long, thin antennae and in the ♂ very easily by the hair pencil at the costal margin of the hindwing, which in the *Lycoreines* is placed at the anus and in the *Heliconines* is generally absent.

Concerning the early stages unfortunately very little is as yet known. The larvae are mostly cylindrical with short tubercles, in some genera with long appendages on segment 2. They are said mostly to live on Solaneae. The pupae, in contrast to the long, thin bodies of the butterflies, are mostly short and stout. They have often brilliantly shining, metallicly glossy surfaces, the gloss of which, however, fades after the death of the pupa.

The butterflies have mostly an elongated body, glossy wings and long antennae. The predominant colour of the wings, in addition to the colourless, glassy tone, is a reddish yellow-brown tinge, combined with blackish, yellow and white markings, this being the so-called „*Lycorea*-habitus“. Blue, red or green is hardly ever met with. According to the more brilliant or more dull colours the different groups prefer more open places or the dense, dark primeval forest. Their flight is mostly irregular and sluggish. In open, unwooded localities only a few forms are occasionally met with.

The area of distribution of the Ithomiids embraces the whole of tropical and subtropical America. Single species occur also in California and in Argentina. They also inhabit the mountains up to elevations of 3000 m. Most species, however, are found below the Equator in the valleys of the Andes. Species of the genera *Mechanitis*, *Ceratinia* and the small transparent *Ithomiinae* especially occur in great abundance. Among them are found singly examples of similar, rare species of the genus *Napeogenes*. Many species have a wide range of distribution and occur, though with slight variations, almost everywhere; others again favour exclusively certain mountain-valleys. One can even sometimes take a few specimens of certain rare species daily in particular localities, although the species is not found elsewhere within a considerable distance.

4. Genus: **Olyras** Dbl. & Hew.

The few species of this genus are large, semitransparent, mostly rare butterflies. They may be distinguished from similar forms of other genera by the strongly sinuate inner margin of the forewing, especially in the ♂, and the broad hindwing with the costal margin correspondingly curved. The ♂♂ have 2 hair-pencils at the costal margin of the hindwing. — They are mountain butterflies, and are fond of floating about in open places mostly at a considerable height above the ground.

O. montagui Btlr. (31 d). Forewing dark brown, with irregular, glassy spots in the distal half. Hindwing reddish brown with dark distal margin and glassy spot at the apex, which on the under surface is prolonged as a band towards the inner margin (in many examples also on the upper surface). This rather rare species flies on the eastern slopes of the Andes of Colombia and Ecuador; it superficially resembles *Ituna lamirus* and also *Dircenna olyras* and *Napeogenes excelsa*, which occur in the same localities, but are distinctly smaller. — **sticheli** Hsch., from Eastern Peru, is very similar to the preceding, but is distinguished by a large red-brown triangle at the base of the forewing. The dark distal margin of the hindwing moreover is broader and the white spots on the under surface are larger. — **staudingeri** Godm. & Salv. (= *centralamerica Stgr. i. l.*), from Central America, is similar to the preceding, but has only one yellow-brown streak at the median of the forewing and smaller yellowish vitreous spots. The colour of the hindwing is yellow-brown. In its apex is placed on the upper surface only a small, transparent spot.

O. crathis Dbl. & Hew., from Venezuela, is similar to the preceding, and also to the following. The oblong spot at the base of the forewing is broader, but light yellow-brown. The vitreous spots are smaller and brownish. The hindwing is light brown with broad dark margin and 2 indistinct vitreous spots. — **theon** Bates (31 d). From Central America; here the vitreous spots are larger, and also the yellow-brown spot at the base of the forewing. Hindwing unicolorous yellow-brown with narrower dark distal margin and light discal spot on the under surface.

O. praestans Godm. & Salv. (31 e) recalls the somewhat larger *Ituna phenarete*. The forewing is vitreous with dark margins and oblique bands. The hindwing transparent yellowish with dark costal and distal margins. On the under surface white double spots are placed at the distal margin and 3 white dots at the costal margin of the hindwing. It inhabits north-eastern Colombia. — **insignis** Salv., from Central America, has red-brown colour at the anal angle of the hindwing and on the underside only 1 white dot at the costal margin.

O. translucens Hew., from western Ecuador, is the smallest and rarest species. It is almost diaphanous, only at the base slightly yellow, with dark margins and a transverse band on the discocellulars of the forewing to the distal margin. On the under surface small white dots are placed at the distal margin.

5. Genus: **Eutresis** Dbl. & Hew.

Here also belong only a few forms, of similar size and colouring to *Olyras*, but without the strongly sinuate margins. They likewise inhabit the mountains, from Peru to Central America.

E. hyperia Dbl. & Hew., the first described form and type of the genus, is very similar to the figured *theope* (31 e). It is somewhat larger, has broader dark margins and bands, and the base of the forewing and the whole disc of the hindwing are reddish yellow-brown. It flies in the mountains of Venezuela. — **hyspa** Godm. & Salv. (= *antioquensis Stgr.*) is a local form of *hyperia* from Ecuador and Colombia, which is distinguished by much weaker red-brown colouring, especially in the disc of the forewing. — **imitatrix** Stgr. (31 e) resembles the species of *Thyridia* and of the transparent *Aprotopos*. But it is very nearly allied to the preceding and differs chiefly by the absence of the red-brown colour on both wings, as well as by the blackish transverse band across the middle of the hindwing. It occurs on the eastern slopes of the Andes of Peru and Ecuador. — **theope** Godm. & Salv. (= *dilucida Stgr.*) (31 e). This is the Central American form of *hyperia*, from Costa Rica. It is distinguished especially by the paler margins and the narrower distal margin of the hindwing, which is proximally edged with yellow-brown.

6. Genus: **Athesis** Dbl. & Hew.

The species of this genus are similar to the preceding, but mostly considerably smaller. They are distinguished by the angled lower discocellular and the long cell of the hindwing. All are mountain species from the north-west of South America.

- clearista*. **A. clearista** Dbl. & Hew. (31e), from Venezuela, has vitreous wings with dark margins and two oblique bands over the discocellular and across the middle of the cell of the forewing. A streak along the median of the forewing and the veins in the disc of the hindwing are yellow-brown. The long antennae are black.
- acrisione*. **A. acrisione** Hew., a beautiful but rare species from Ecuador, is considerably larger; the apex of the forewing margined with yellow-brown. Across the end of the cell of the hindwing to the inner angle runs a black band, part of which is confluent with the distal margin. In the latter are placed also above large, white submarginal dots.
- dercyllidas*. **A. dercyllidas** Hew. (32a). The wings have the appearance of greenish glass; especially on the under surface the glassy spots are more strongly margined with green. Some of the dark margins and bands on the upperside are bordered with yellow-brown. On the underside they are yellow-brown with dark edges. In the pattern and the greenish colouring the species recalls *Colaenis dido*; it flies in Colombia and Ecuador. —
- demytus*. GODMAN and SALVIN designate as **demytus** a form from southern Ecuador with very narrow margins and bands.
- hewitsoni*. **A. hewitsoni** Srnka. This species was figured by HEWITSON as ♂ to *dercyllidas*, but recognised by SRNKA as a separate species. It differs in the brownish tone of the hyaline spots and the narrower margins and bands of both wings. In the oblique band across the end of the cell of the forewing is placed towards the distal margin another oblong hyaline spot.
- oligyrtis*. **A. oligyrtis** Hew. is a further form from Ecuador, similar to *dercyllidas*. It is said to have an indistinct band between the discoidal veins before the distal margin of the hindwing, and also 3 white dots at the costal margin; in addition a black band from the apex of the hindwing to the 1. median vein.

7. Genus: **Thyridia** Hbn.

In this genus, which DOUBLEDAY and HEWITSON call *Methona*, belong only a few larger species with transparent, black-marked wings and thin black antennae provided with stronger, yellow club. The cell of the hindwing is small and closed almost at right angles to the median. The species belong mostly to the plains and occur from Guiana to Argentina and westwards to the Upper Amazon.

- confusa*. **Th. confusa** Btlr. (= *psidii* Cr.) (32a). This species was long taken for the similar *psidii* of LINNÉ, which, however, belongs to quite another genus. The latter (pl. 34c) is easy to recognise, in addition to the neururation, by the small reddish dots at the base of the forewing. *confusa* has transparent yellowish wings with black margins and a transverse band on the discocellular of each wing, as well as a transverse streak through the cell of the forewing. It occurs on the Lower and Uppér Amazon, and in Guiana, in the shady places of banks of rivers. —
- psamathe*. **psamathe** Godm. & Salv., from eastern Ecuador and Peru, is a local form with narrow bands and margins. According to GODMAN and SALVIN there is a corresponding form of *Dismorphia orise*, whose ♀ very nearly resembles that of *Th. confusa* and which occurs in the same localities as *psamathe* and is said likewise to have narrower bands and margins. —
- curvifascia*. **curvifascia** Weym., from Ecuador and the Upper Amazon, is a form in which the black at the base of the hindwing is extended beyond the point of origin of the 1. median vein.
- themisto*. **Th. themisto** Hbn. (32a). May be distinguished from the similar *confusa* by the absence of the broad transverse band on the discocellular of the hindwing. The larva according to W. MÜLLER lives on species of *Brufelsia*. It is deep velvety black with orange-coloured belts. The pupa is elongated, immovable, white-yellow with narrow orange-coloured transverse bands and black stripes and spots. The species lives in central and southern Brazil to Argentina. —
- megisto*. FELDER describes as **megisto** a form of the preceding from Bahia, which is said to be larger and to have the veins less margined with black. On the other hand the median band of the forewing is much broader and the distal margin of the hindwing irregular.
- singularis*. **Th. singularis** Stgr., likewise from Bahia, is smaller than *themisto* and has the inner margin of the hindwing not dentate at the 2. median vein and on the upper surface edged with white. The costal margin of the hindwing beneath is broadly yellow at the base and not interrupted with black on the precostal vein.

8. Genus: **Tithorea** Dbl. & Hew.

In this genus 2 quite different groups were formerly included and I am compelled to separate the second group under the name of *Hirsutis*. The principal differences are the following: In *Tithorea* the eyes are hairy, the tibiae of the middle and hindlegs are much longer than the femora. The ♂♂ have only 1 hair-tuft at the costal margin of the hindwing. In *Hirsutis* the eyes are naked; the tibiae of the middle and hindlegs are

not much longer than the femora and the ♂♂ have 2 hair-tufts. The species of the genus *Tithorea* have short broad wings with black ground-colour. They are not at all like the other Ithomiids and recall the *Danais*-species in the shape of the wings. They inhabit the north-west of South America to Panama.

T. humboldti Latr. (= *flavomaculata* Stgr.) (32a). A stately, velvety black butterfly with yellow *humboldti*. macular band across both wings and yellow subapical spots on the forewing. On the under surface the forewing has also yellowish stripes at the base and behind them a double spot. The hindwing has beneath at the base a yellowish streak and a further oblique band, as well as a brown spot outside the cell. In addition both wings bear a row of white submarginal spots. From the Cauca Valley in Colombia, according to LATREILLE also from the Amazons (?). — As *albomaculata* Hsch. I have designated a form in which the spots on the forewing are white. It appears to be commoner than the typical *humboldti*, and occurs on the eastern slopes of Ecuador and Colombia at elevations of ca. 1500 m. *albomaculata*.

T. cassandina Srnka, from Ecuador, is a smaller species, similar to *albomaculata*. The yellow spots *cassandina*. of the hindwing are very small, on the contrary the brown spot on the under surface at the end of the cell is very large. The submarginal spots on the underside are bluish white. The species recalls *Heliconius cassandra* Fldr.

T. bomplandi Guér. (32b) is the commonest species of the genus. On the upperside the forewing has *bomplandi*. besides the spots of *albomaculata* also the white streak and double spot of the underside. The hindwing is marked as in *pavonii* (figured on the upper surface), only proportionately larger. Comes mostly from Colombia, but also from Bolivia. — *descandollesi* Stgr., from the Cauca Valley in Colombia, is a form in which all the normally white spots of the upper surface are yellow. — *latreillei* Stgr., likewise from the Cauca Valley, has the yellow spots like *descandollesi*, but the band of the hindwing is much broader and behind it follows a further yellow macular band almost as in *humboldti*. On the under surface the brown spot at the discocellular is much smaller, but continued by 2 smaller spots. *descandollesi*. *latreillei*.

T. regalis Stich. (= *dagua* Stgr. i. l.) is very similar above to *bomplandi*, except that the white *regalis*. spots at the discocellular of the forewing are perceptibly larger. Beneath on the contrary the ground-colour is principally brownish except on the disc of the forewing and the bordering of the white spots and dots. The species comes from the Rio Dagua in Colombia.

T. pavonii Btlr. (32b) is the smallest species of the genus and above similar to *bomplandi*. Streak and *pavonii*. double spot at the base of the forewing are yellowish. On the under surface some of the spots at the end of the cell of the forewing are also yellowish and on the hindwing there are 2 complete rows of brown spots between the rows of white dots and the oblique band. BUTLER describes the species from Panama and compares it with the similar *Heliconius peruvianus*. But it occurs also in western Ecuador and Peru, as well as in Bolivia. In Ecuador it flies with the confusingly similar *Heliconius atthis* in the same localities.

T. tamasea Hew., from Colombia, has some similarity to *descandollesi*, but the yellow spots at the base *tamasea*. and at the end of the cell of the forewing are absent; moreover the yellow band of the hindwing is narrower and abbreviated. On the under surface both wings have whitish marginal dots. The forewing has a brownish band near the median and 2 brownish spots near the apex. The hindwing has further 2 brownish bands at the base and in the disc before the yellow spots. In an aberration from the same locality the band of the hindwing is reduced to 2 spots, of which the distal one is partly brownish. On the under surface almost the whole disc of both wings is brownish. — A further form, which I call *lugubris* form. nov., has the upper surface *lugubris*. of the wings unicolorous black-brown, only the minute white double dots in the distal margin of both wings remain. On the under surface there are also a brown subapical band on the forewing and submarginal band on the hindwing. The form comes likewise from Colombia.

9. Genus: **Hirsutis** gen. nov.

The distinctive characters of this genus have already been given under *Tithorea*. It may further be divided into 2 large groups, namely: a) Wings short and broad, patagia black-brown. b) Wings elongate, patagia red-brown. The species of the first group recall *Danais* and *Tithorea* by their wing-contour; those of the 2. group have pronounced „*Lycorea*-habitus“. The species are distributed over the whole Neotropical region from Mexico to South Brazil. They are mostly found singly at the edges of the woods or at flowering shrubs with the corresponding species of *Melinaea*, *Mechanitis* and *Ceratinia*.

a) Patagia black-brown.

H. pinthias Godm. & Salv. (32b). A stately butterfly with broad wings. Forewing black-brown with *pinthias*. 12 irregular yellow spots. Hindwing red-brown with dark costal and distal margins. On the under surface the hindwing has in addition a dark oblique band from the apex to the inner margin, at the beginning of this

band is placed a larger, yellow spot. Both wings have beneath white distal-marginal dots. This form occurs especially in Panama and Costa Rica.

tarricina. **H. tarricina** Hew., from Colombia, is nearly allied to the preceding, but has at the apex of the hindwing 3 larger, yellow spots. — **hecalesina** Fldr. (32c), likewise from Colombia, has towards the dark distal margin of the hindwing proximally a complete band, composed of large yellow spots. Moreover the whole costal margin of the forewing is dark brown as far as the median. — GODMAN and SALVIN designate as **parola** a form from the Cauca Valley, in which the costal margin of the hindwing is only narrowly black, so that the dark spot at the apex stands out distinctly. — On the other hand I call **obscurata** ab. nov. an aberration from Colombia in which almost the whole hindwing except a spot at the inner angle is black-brown.

bonita. **H. bonita** Hsch. represents the *Pinthias*-group in eastern Ecuador. In this is placed on the hindwing between apex and discocellular a rounded blackish spot and on the under surface in addition 2 further spots in the disc, which form an oblique band with the subapical spot.

duenna. **H. duenna** Bates, from Guatemala and Honduras, differs strikingly from the preceding in a blackish oblique band from the apex of the hindwing nearly to the middle of the inner margin, as well as in a reddish, oblong spot at the base of the forewing. Moreover the collar is red-brown. BATES found the species only on the tableland of Duenas in Guatemala. — **monosticta** Godm. & Salv., from Panama and Costa Rica, is said to be distinguished from *duenna* by the absence of the dark band on the upper surface of the hindwing, but to have a macular band on the under surface.

irene. **H. irene** Drury, from Jamaica, is a form similar to *tarricina*, with only 2 yellow spots at the apex of the hindwing and 2 dark spots outside the cell, as well as a red-brown spot at the base of the forewing. — **umbratilis** Bates, from Panama, differs from the preceding by the absence of the red-brown spot at the base of the forewing and also of the yellow spots at the apex of the hindwing. The antennae are brownish, at the base blackish.

helicaon. **H. helicaon** Godm. & Salv. has larger, yellow spots on the forewing and 2 red-brown longitudinal spots at the base. The hindwing has narrower margins and no dark spot on the disc. The habitat is Costa Rica.

tagarma. **H. tagarma** Hew., from Bolivia, is a rare species with somewhat narrower wings, larger yellow spots and large red-brown spot at the base of the forewing. The hindwing is light reddish yellow-brown with narrower dark margin and yellow oblique macular band behind the discocellular. — In the local form **anachoreta** Thieme, from Peru, the yellow oblique band is shorter and broader, and behind the discocellular of the hindwing is placed an oblong blackish spot. The antennae are black. Collar red-brown.

b) Patagia red-brown.

hippothous. **H. hippothous** Godm. & Salv. (32c). This species forms the transition between the two groups. The patagia are still darker brown; the hindwing broad, but with macular longitudinal band and the antennae except at the base yellow-brown. The species differs from *irene* Drury in the two red-brown longitudinal spots at the base of the forewing and the band-like spots in the disc of the hindwing.

hermias. **H. hermias** Godm. & Salv. Markings as in the figured *neitha* Hpffr. Colour on the basal half of the forewing and on the hindwing vivid red-brown. The bands and spots in the apex yellow. The black marking of the hindwing is narrower. This is the form from eastern Ecuador, whilst *neitha* Hpffr. (32c), from eastern Peru, is distinguished by the yellow ground-colour of both wings, especially on the under surface. — **egaënsis** Btlr., from the Upper Amazon, is distinguished from the preceding by the rusty ground-colour of both wings and by the very small white marginal dots of the under surface. — **melanina** Hsch. is a form of *egaënsis*, likewise from the Upper Amazon. It differs in the absence of the yellow colouring and has already been mentioned under *Lycorea concolor*. — Whilst *hermias* and the allied forms have all a spear-shaped marking behind the end of the cell of the forewing towards the distal margin, in

hermina. **H. hermina** Hsch. (32d) the yellow oblique band of the forewing is broken up into about 10 smaller spots. This is a form of *hermias* from the eastern spurs of the Andes at the River Napo in Ecuador. — A further form from the same localities, **napona** Hsch., is distinguished by narrower distal margin to the hindwing and the absence of the blackish macular band.

brunnea. **H. brunnea** Hsch., from eastern Peru, is superficially similar to *melanina* in the absence of the yellow colouring. In the markings, however, it approximates to *napona*. It has likewise narrow distal margin to the hindwing and the dark macular band is only feebly indicated.

pseudonyma. **H. pseudonyma** Stgr. has similar markings to *hermias*. It may be recognised by having mostly only 3 isolated blackish spots in the disc of the hindwing. The yellow oblique band of the forewing

encloses at the end of the cell only a smaller dark spot and terminates at the distal margin in a more spear-shaped point. This species occurs in Bolivia, Paraguay and Argentina. — In southern Brazil occurs the similar *pseudethra* *Btlr.* (32 d), which is distinguished by the characteristic yellow longitudinal band of the hindwing *pseudethra*, and has already been mentioned under *Lycorea halia*. — I have described as *assimilis* *Hsch.* the form of *pseudonyma* without yellow colouring, in which it resembles *melanina* and *brunnea*. *Assimilis* is, however, easy to recognise by the 3 isolated spots in the disc of the hindwing. It occurs, like the similar forms, on the Upper Amazon. — As *lateflava* *form. nov.* I designate yet another form of *pseudonyma* with very broad yellow oblique *lateflava*, band on the forewing; this band is suddenly narrowed to a small, rounded point close to the distal margin. In it are placed in addition to the spot at the end of the cell 2 small dark dots before the distal margin. This form comes from Santa Cruz in South Bolivia.

H. harmonia *Cr.* (32 d). In the typical specimens of this species from Guiana the dark longitudinal band *harmonia*, of the hindwing is confluent with the dark distal margin into a large patch, as in *Lycorea ceres* and many Ithomiids. The forewing is pointed, especially in the ♂. The yellow oblique band ends in three points. — The form with normal *Lycorea*-habitus and separated bands is *mopsa* *F.* In this the macular band of the hindwing is narrowed towards the inner margin; ground-colour red-brown. It occurs in Guiana and on the Lower Amazon. — A local form with light yellow-brown ground-colour from the Antilles and Trinidad has been called by GODART *megara* (= *flavescens* *Kirby*). — According to GUPPY the larva of this form is black with white dots *megara*, and 2 long, immovable, antenna-like appendages on the 2. segment. It feeds by day on *Echites* sp. The eggs are similar to those of *Lycorea ceres*, yellowish with numerous impressions, and are laid singly on the underside of leaves.

H. cuparina *Bates* is unknown to me. According to the description it approximates to the following *cuparina*, species (*furia*), as the yellow oblique band of the forewing is said to terminate obtusely. BATES compares it with the common form from the Amazon and says that it is only to be found at the southern tributary of the Middle Amazon, the Tapajos.

In the following forms the longitudinal band of the hindwing is still more distinctly pointed proximally.

H. salvadoris *Stgr.* This large species resembles *hippobous*. It occurs also in Central America (San *salvadoris*, Salvador, Honduras), but has lighter, yellow-brown ground-colour and larger yellow spots. It approaches the following forms in the keel-shaped band of the hindwing.

H. furia *Stgr.* (32 d) may be distinguished from the similar species by the yellow oblique band of the *furia*, forewing, which terminates obtusely at the distal margin, and by the proximally pointed longitudinal band of the hindwing. It flies in Venezuela and Colombia. — In *furina* *Godm. & Salv.* the oblique bands of the forewing *furina*, are broken up into small yellowish spots. It is commoner and more widely distributed than the typical *furia*, occurring in western Ecuador and South Bolivia as well as in Colombia and Venezuela. — *flacilla* *Godm. & Salv.*, *flacilla*, from the Cauca Valley in Colombia, differs from the preceding in having 3 yellow spots at the apex of the hindwing, which are margined with black; also the base of the forewing is more broadly blackish and the brownish basal streak-spots are correspondingly smaller.

10. Genus: **Athyrtis** *Fldr.*

In size and markings the species of this genus are very similar to those of *Melinaea*, but are distinguished at once by the shorter antennae and the angled lower discocellular of the hindwing. (In the figure of *Ath. mechanitis*, pl. 33 a, the neurulation is indistinct).

The few forms of this genus are all very rare and occur only on the eastern slopes of the Andes from Colombia to Peru.

A. mechanitis *Fldr.* (33 a) has the markings almost as in *Mechanitis doryssus*, but is considerably larger *mechanitis*, and may be recognised by the angled lower discocellular of the hindwing. The base of the forewing and the hindwing are red-brown; the former with blackish apical half and 3 yellow macular bands, the latter with yellow and black macular band, as well as dark distal margin. Both wings with small white marginal dots. — In the local from *oberthueri* *Srnka*, from Ecuador, the yellow longitudinal band of the hindwing is absent, and the *oberthueri*, bands of the forewing are smaller. — In *salvini* *Srnka*, from eastern Peru, the red-brown colour is duller and *salvini*, extends on the forewing beyond the discocellular. Apex and distal margin are black-brown with yellowish subapical band. At the end and again in the middle of the cell there is a black spot. The hindwing has a central row of 5—6 black spots and narrow, dark distal margin. — In a local form from the Upper Amazon, which I call *amanga* *form. nov.*, the whole apical half of the forewing is black-brown. In this is placed in addition to the *amanga*, yellowish, very narrow subapical band a brownish band near the end of the cell. Of the two black spots in *salvini* the distal one is suppressed in the dark apical half.

distincta. **A. distincta** Hsch. Similar to *mechanitis*. The subapical band of the forewing is small, the median band is proximally curved and encloses a large black spot at the end of the cell; the proximal band consists only of a spot in the cell. The hindwing has on the under surface at the end of the cell a large yellow spot which shows through slightly above.

11. Genus: **Melinaea** Hbn.

This genus contains numerous stately species of rather large size and mostly of red-brown ground-colour. They may be recognised by the long yellowish antennae and the long cell of the hindwing, with apparently 4-branched median. The Melinaeas are distinguished from the often very similar *Mechanitis*-species by the normal forelegs, which in *Mechanitis*-♂♂ are reduced to a knob and which in the ♀♀ have 4 joints to the tarsi. Moreover *Mechanitis* has much shorter antennae. The *Heliconius*-species, which are likewise often very similar superficially to *Melinaea*, are recognised by the small cell of the hindwing and the absence of the hair-brushes in the ♂♂. The *Melinaea*-species are distributed over the whole Neotropical region from Mexico to Argentina, but are mostly not very abundant, occurring singly in company with the corresponding species of *Mechanitis* and *Ceratinia*. The ♂♂ have 2 pairs of hair-tufts, of which the first (at the base) is pencil-shaped, the 2. (at the end of the cell) is broad and comb-like.

- zaneka*. **M. zaneka** Btlr. (= *dora* Streck.) (32c). This beautiful, large species is distinguished from most of the other forms by the absence of the dark longitudinal band in the disc of the hindwing. The forewing shows the *Lycorea*-habitus, but without the yellow subapical spots. The dark distal margin of the hindwing is narrow and only present in the apical half. The species occurs only in eastern Ecuador, mostly in the dusk of the primeval forest on undergrowth. — In ab. **maculosa** Hsch. the ground-colour is darker red-brown. The hindwing bears in addition one or two incomplete, dark longitudinal bands, as in *menophilus*. — In a further interesting aberration, which I call ab. **discurrens** ab. nov., the ground-colour is likewise darker. At the distal margin of the hindwing are placed large dark brown projections and between the end of the cell and the apex a dark zigzag line runs from the costal to the distal margin.
- menophilus*. **M. menophilus** Hew. (= *ishka* Btlr.) (32c). A widely distributed species; it is smaller than *zaneka*, has a broader, dentate oblique band on the forewing and on the hindwing 2 blackish macular longitudinal bands. It occurs in the eastern Andes from Colombia to Peru. — In the local form **cocana** Hsch., from the upper Napo in Ecuador, the two bands of the hindwing are united into a large spot, in which the veins still remain finely brownish. — In the local form **maenius** Hew. the ground-colour is dark red-brown and the black bands and patches are very large, partly confluent. From the Upper Amazon (Teffé). — As **tarapotensis** form. nov. (*Bang.-H. i. l.*) I designate another form with duller ground-colour from Tarapoto on the Upper Amazon. Here the oblique band of the forewing is narrower; the dark bands of the hindwing are larger and diffuse. On the under surface the dark markings at the costal margin and in the disc of the hindwing are absent. — **chíncha** Druce is a form of *menophilus* in which the yellow oblique band of the forewing is absent; it has already been mentioned with the similar forms under *Lycorea concolor*. It comes like these from eastern Peru, and has the black patches exactly as in *menophilus*.
- messenina*. **M. messenina** Fldr. has the appearance of *Mechanitis messenoides* Fldr. (33f), the forewing similar to *menophilus*, the hindwing is however black-brown except for a red-brown subapical spot. In eastern Colombia and Ecuador. — **mothone** Hew. (= *cydippe* Salv.) (32e). Here the yellow oblique band is absent. The colour consequently appears plain black-brown with broad red-brown-oblique band with black spots in it. The following from other genera have very similar markings: *Mechanitis deceptus*, *Ceratinia bicolora* and *semifulva*, *Hypocada fallax*, and also *Heliconius aristiona* and their varieties. *mothone* occurs on the eastern slopes of the Andes from Colombia to Peru and Bolivia in slightly differing forms.

All the preceding species of *Melinaea* have a broad black apex to the forewing. The following forms have all a yellow or brownish subapical macular band.

- marsaeus*. **M. marsaeus** Hew., from the Amazons, is similar to *menophilus*, but has a narrower, curved yellow oblique band, which has proximally another spur behind the middle. The black spots at the end of the cell and in the basal part are joined together. In the black apical part are placed 3 oblong red-brown spots.
- divisa*. **M. divisa** Stgr. is similar to the preceding in the markings. The yellow oblique band is however suppressed by the red-brown ground-colour. Moreover a yellow macular band is placed in the apex. — In the first described *lucifer* **lucifer** Bates (33a) the two longitudinal bands of the hindwing are confluent. Both forms occur on the Upper Amazon.
- flavosignata*. **M. flavosignata** Stgr. (= *egesta* Godm. & Salv.) has a broader yellow oblique band than *menophilus* and a yellow macular band in the apex. The habitat is Colombia and East Peru. — In **hicetas** Godm. & Salv. (32e) the yellow oblique band is suppressed by the red-brown ground-colour. Examples, however, occur like the

figure, in which some yellow colour is to be seen at the costal margin. — In *magnifica* Hsch. the subapical spots have also become completely red-brown. — *orestes* Salv. is said to be similar to *lucifer*, without the yellow spots at the costal margin and in the apex of the forewing. The hindwing is as in *hicetas*. — *phasiana* Btlr. (33a) differs from *magnifica* in the red-brown, black-margined apex. It is very similar to *Mechanitis mazaeus*. All these forms come from the Upper Amazon, from eastern Peru. — *macaria* Godm. & Salv. has the forewing as in *flavosignata*, except that the two oblong spots at the base are considerably larger. The hindwing has a large black spot as in *lucifer* and *messenina*. From North-East Colombia.

M. mneme L. (= *crameri* Godm. & Salv.) (33a). has likewise a black-brown spot on the hindwing, which, however, extends to the costal margin, the base and a subapical spot remain red-brown. The oblique band of the forewing is narrower and in the middle dentate; the spots at the base are rounded. Flies only in Guiana and on the Lower Amazon.

M. mediatrix Weym. (33b), a superficially very similar, but sharply separated species, occurs on the contrary both on the Upper and Lower Amazon and also in Guiana. The forewing has at the base a pointed double spot, the hindwing at the costal margin a red-brown band. Moreover, the hindmargin of the forewing is broadly black, not so in *mneme*. — In the form *mauensis* Weym. the black patch of the hindwing is broken up into 2 bands. — In a further form, which I call ab. *anina* ab. nov., the yellow oblique band of the forewing is broken up into 2 small spots: one at the end of the cell, the other (oblong) in the black apical half at the distal margin. From British Guiana.

M. satevis Dbl. & Hew. (33a) has the markings on the forewing as in *mneme*, but the ground-colour is a peculiar wine-red, as is the case in only a few other forms, such as *Melinaea madeira* and *Ceratinia viola*. The hindwing is wine-red with dark distal margin and the indication of a longitudinal band in the apex, which is more distinct on the under surface. On the underside the distal margin has small white marginal dots as in *mneme*. Bolivia.

M. maelus Hew. (= *pardalis* Bates) has markings and colouring like *cydon* Godm. & Salv. (33b), but is distinguished by a yellow oblique band across the end of the cell of the forewing nearly to the distal margin, which is absent in *cydon*. A very similar pattern recurs in *Ceratinia castanea* and *anastasia*. All these species fly on the Upper Amazon. HEWITSON describes under *maelus* another form, which he considers a variety, but which belongs to quite another species. I call it:

M. manga spec. nov. It has a lighter, red-brown ground-colour, a dark apex to the forewing with red-brown spots and 2 very small yellow ones. The basal half and the hindwing are as in *marsaeus*, except that the median band is stronger and wedge-shaped. From the Amazons.

M. madeira (Stgr. i. l.) (33b) has a yellow oblique band like *maelus*, but this is extended into the cell and to the 1. median vein. The ground-colour is wine-red, the apex dark. The median band of the hindwing consists of 3 larger oblong spots and 1 small one. This form from the Upper Amazon (Manicoré) appears to be commoner than *maelus* and *cydon*.

M. maeonis Hew., from the upper Napo in Ecuador, has a pattern similar to that of *maelus*, but the whole apical half of the forewing is black-brown except for the narrow transverse band and the 3 large subapical spots. The hindwing has a dark distal margin and a curved macular band, which is connected at the apex with the dark costal margin. — On the Ucayali in Peru occurs a nearly allied form, which I call *zamora* form. nov. (*Bang-H. i. l.*). Here the ground-colour is much lighter, especially before the middle of the wing, and the hindwing is distinguished by a light yellow longitudinal band between the costal margin and the dark median band. The distal margin is only very narrowly edged with dark.

M. mnemopsis Berg (= *boliviana* Stgr. i. l.) (33d). This species has only the beginning of the yellowish and dark bands of *zamora* at the apex of the hindwing. The distal margin is broadly edged with blackish, beneath with distinct white dots. On the forewing the yellow median band is divided into 2 spots. This large form comes from Peru and Bolivia.

M. scylax Salv. (= *ribbei* Weym.) (33c), from Costa Rica, has a unicolorous yellow-brown hindwing with narrow dark distal margin. The forewing has the usual bands and spots with large black spots in the disc.

M. lilis Dbl. & Hew., from Venezuela, and *imitata* Bates (= *tachypetis* Fldr.) (33c), from Central America and Mexico, are very closely allied. In *lilis* the median band of the forewing is continuous and brownish; in *imitata* it is yellow and divided. Moreover, in *lilis* the central subapical spot is much larger. — In the genus *Ceratinia* there are likewise 2 very similar forms from Central America and Venezuela: *dionaea* and *fraterna*, and again *Heliconius telchinia* and the allied forms are confusingly similar to the two Melinaeae.

M. ethra Godt. (= *phasis* Fldr.) (33d). This typical South Brazilian species may be at once recognised by the yellow longitudinal band of the hindwing and the isolated yellow subapical spots of the forewing. It has been already mentioned under *Lycorea halia* with the similar forms. It especially resembles *Heliconius narcaea* (= *eucrate*), with which it flies together.

- thera*. The small **M. *thera*** Fldr. has also a similar pattern, but approximates more nearly to ***mnasias*** Hew. (33 d).
mnasias. *thera* is the same size as *mnasias* and has the same markings with the addition of a large white subapical spot on the forewing and small white marginal dots. It has further a yellow longitudinal band on the hindwing like *ethra*. The typical specimens of *mnasias* from the Amazons have white marginal dots and 2 larger, yellow spots in the end of the cell and before the oblique band. In the example figured from British Guiana these spots are
tecta. absent and the marginal spots are yellow. I consequently call this local form ***tecta*** form. nov.
- equicola*. **M. *equicola*** Cr. is very similar to the figured *Mechanitis equicoloïdes* (33 e). The black spots at the end of the cell of the forewing and at the distal margin form a band and before this is placed a yellow oblique band. The black spot between the median veins in the disc is absent. On the hindwing the median band and the very broad distal margin are confluent at the inner angle.
- idae*. **M. *idae*** Fldr. (33 c) is an entirely isolated species from Colombia and Ecuador. The yellow apical spots are as in *mneme*, on the other hand the yellow oblique band is abbreviated and towards the base widened. The hindwing is conspicuous by the absence of the longitudinal band and by the very broad dark distal margin. On the under surface both wings have small white distal-marginal dots. The example figured is from Colombia; the specimens from Ecuador differ in the smaller size and narrower distal margin of the hindwing, which is sharply defined proximally. *Ceratinia philetaera* and *Heliconius clara* have similar markings to *idae*.
- paraiya*. **M. *paraiya*** Reak. (33 c). Between the yellow subapical and median band are placed 2 spots in the black apical half of the forewing and in the cell two black spots. The hindwing has dark distal margin and a macular band. This common species occurs in Guiana and on the Amazons as well as in Central and South
egina. Brazil; it is very similar to *Mechanitis macrinus* and also to *Heliconius metaphorus*. — In the allied ***egina*** Cr. the median spots of the band of the hindwing are merged with the distal margin into a large spot. In the forewing there is a third yellow spot between the two median ones. This form flies especially in Guiana and on the Middle Amazon.
- messatis*. **M. *messatis*** Hew. (33 d) forms with the two following varieties a small separate group which closely resembles *Heliconius ismenius*. Particularly striking are the numerous white spots on the forewing. The median band of the forewing is only developed in the apical half. *messatis* occurs in Colombia, whilst the nearly allied
parallelis. ***parallelis*** Btlr. flies in Panama. The latter has a complete longitudinal band on the hindwing. — ***dodona*** Hpffr.,
dodona. from Bolivia, has on the forewing besides the marginal dots yellow instead of white spots. The hindmargin of the forewing is black, the band of the hindwing complete.

12. Genus: **Mechanitis** F.

The differences between this genus and the often very similar *Melinaea* have already been given under the latter. The species are smaller throughout, have long, narrow wings and shorter antennae. In colour and markings the *Lycorea-habitus* predominates.

This genus has a very wide range; species occur almost everywhere from California to Argentina; many forms, especially in the primeval forests of the plains, occur at times in such enormous numbers as are otherwise attained only by certain colourless Ithomiids. At such times the bushes at particular places are literally covered with them. *Mechanitis* also produces every possible variety of colouring. Most forms vary so much that one can arrange an almost uninterrupted series of transitions between all the varieties. Many specimens are indeed difficult to place with a definite species, and hybridisation apparently occasionally takes place between nearly allied forms.

- polymnia*. **M. *polymnia*** L. (33 e). Typical examples of this very variable species, with small subapical spot and large yellow median band on the forewing, occur especially in Guiana and on the Lower Amazon. The two black spots at the end of the cell are mostly confluent. The median band of the hindwing is broad and dentate.
chimbora-
zona. — ***chimbrazona*** Bates is a local form from the western slopes of the Andes in Ecuador, with very broad yellow median band at the costal margin of the forewing, which is suddenly narrowed into a streak behind the cell. The ♂♂ have in the hindwing a very broad black median band; in the ♀♀, however, this is only
casabranca. present at the apex. — ***casabranca*** Hsch. is the local form from Central and South Brazil, which is easy to recognise by the characteristic yellow longitudinal band in the hindwing. Moreover the yellow subapical spot in the forewing is absent and the double spot at the end of the cell is widened at the costal margin. The median
caucaënsis. band of the hindwing is narrow. — I designate as ***caucaënsis*** form. nov. the form from the Cauca Valley in Colombia. This is distinguished by dark brown-red ground-colour, large yellow band-spot and small black spots at the end of the cell of the forewing. The black spot in the cell is produced into a point. The broad median band of the hindwing in the ♂ is almost edentate.
- equicoloïdes*. **M. *equicoloïdes*** Godm. & Salv. (33 e). This and the following form differ from all the others in the larger size and more powerful build. But the marking is similar to that of *doryssus*. Very striking are 2 black, isolated spots at the costal margin of the hindwing. Whilst the form *equicoloïdes* from the Upper Amazon

has on the hindwing the usual pattern with black, dentate longitudinal band and similar distal margin, in the allied *sylvanoides* Godm. & Salv., from Guiana, the two bands are confluent at the inner margin. The *sylvanoides* latter form is said to resemble *Heliconius sylvana*.

M. pannifera Btlr. (= *plagifera* Stgr.) (33e). Here the median band and the distal margin of the hindwing are merged into a black patch as in *Melinaea cocana*. The costal margin and apex remain red-brown. The yellow oblique band of the forewing is narrower than in *polymnia*, at the apex there is mostly a yellowish spot. This form occurs both on the Amazons and in Guiana and Venezuela.

In **M. messenoides** Fldr. (33f) the black patch of the hindwing also occupies the whole costal margin, moreover the base of the forewing is also black, and the yellow subapical spot is absent. This species corresponds exactly to *Melinaea messenina*. On the eastern slopes of the Andes, from Colombia to Peru. — Just as in the *Melinaea* there is also in the *Mechanitis* a form without the yellow oblique band of the forewing, namely **deceptus** Btlr. (= *mothone* Salv.). This is deceptively similar to *Melinaea mothone*. It occurs on the Upper Amazon in Ecuador, Peru and Bolivia. But there are also transitions to the preceding form, in which yellowish colour is present at the discocellular of the forewing. — In **meterus** Hew., also from the Upper Amazon, a form which is otherwise marked like *deceptus*, there are 2 more round yellow spots at the distal margin of the forewing. — In **nigroapicalis** Hsch. the base of the forewing and the costal margin of the hindwing are red-brown. In many specimens the median band of the hindwing and the distal margin are completely separated. — **mazaesus** Hew. (34a) has in addition a red-brown patch in the apex of the forewing. — In **phasianita** Hsch. this subapical spot is very large and the black marking in the apex is considerably less extended, so that this form has much the appearance of *Melinaea phasiana*. It occurs like *mazaesus* on the Upper Amazon and its tributaries in Peru and Ecuador. — **lucifera** Hsch. again forms a transition to the forms with yellow oblique band and subapical spot. The marking is as in *phasianita*, but the subapical spot and the oblique band are yellow, with brownish margin. This form, which may be recognised by the strikingly large subapical spot, likewise occurs on the Upper Amazon in Peru.

M. visenda Btlr. has a narrower, yellow oblique band on the forewing, which does not reach to the end of the cell; on the other hand broader, black bands at the inner margin of the forewing and in the disc of the hindwing, as well as narrow distal margin to the hindwing. It flies on the Lower Amazon and Tapajos.

M. fallax Btlr., from Colombia, has likewise a narrower, yellow oblique band and small black spots at the discocellular of the forewing, as in *messenoides* Fldr. The costal margin and apex of the hindwing are red-brown. The black median band is confluent with the distal margin.

M. egaënsis Btlr. (34a), from Ega on the Upper Amazon, has dark red-brown ground-colour. The oblique band is large and one half of it brownish. The black spot at the base is large and wedge-shaped. The hindwing has broad median bands and strongly dentate dark distal margin. — **obscura** Btlr. is a very dark form of *egaënsis* with broader black bands and occurs at the same localities. — In **plagigera** Btlr. the black bands and patches are much narrower than in *egaënsis*; the subapical spot is smaller and yellow, like the more elongated band of the forewing. From Prainha on the Amazon.

M. truncata Btlr. belongs to a small group with shorter wings, in which the apex of the hindwing is almost truncate. It has a pattern like *egaënsis*. The wings are red-brown, the black streak at the inner margin of the forewing is long. In the apex of the forewing is placed a large yellow spot with brown margins. The form varies very much and flies together with *egaënsis* and *obscura* near Ega. — **juntana** Hsch. (34a) has a very narrow, strongly dentate yellow band on the forewing, a similar black median band and very narrow margin to the hindwing. The ground-colour is light yellow-brown. The form flies in eastern Ecuador and Peru, at the base of the Andes. It is at times very common at flowering shrubs. — A nearly allied form is **huallaga** Stgr. (34a), from eastern Peru. It bears, however, a greater resemblance to *phasianita* and *olivencia* on account of the absence of the yellow markings and the smaller extent of the black ones on the forewing. It is easy to recognise by the narrow distal border of the hindwing. — The similar **olivencia** Bates has broader, black bands and patches, as well as a yellow spot at the discocellular of the forewing. It occurs likewise on the Upper Amazon. — **jurimaguënsis** Stgr. has lighter, red-brown ground-colour than *olivencia* and the yellow spot at the discocellular of the forewing is absent. The median band of the hindwing is broadly dentate and sometimes confluent with the broad distal margin.

M. proceris Weym. This small species has the appearance of *juntana*. It may, however, be recognised by the black distal margin of the hindwing being broader and the black streak at the inner margin of the forewing terminating obtusely. From Tonantins on the Upper Amazon.

With **M. doryssus** Bates (33f) we pass to another group of forms which are distinguished by long, narrow wings and mostly inhabit Central America or the adjoining north-west of South America. They have mostly

a similar pattern as in the preceding forms, i. e. on the forewing *doryssus* has in the black apical half an undulate yellow oblique band and a subapical spot. The basal half of the forewing and the hindwing are red-brown; the former with 2 black spots and black margins, the latter with narrow median band and distal margin. In Central America, from Costa Rica to Honduras. — REAKIRT designates as **utenaia** a form from Honduras in which the oblique band of the hindwing is broken up into 2 spots. — **veritabilis** Btlr. is the form from Colombia and Venezuela, with narrow wings. Here the club of the antenna is yellow-brown, in *doryssus* only the base is dark. The ground-colour of the wings is darker. This form flies also on Trinidad. — **saturata** Godm. & Salv. is a similar, larger form from Mexico with very narrow yellow bands in the forewing, broader black apex and large basal spots. — **labotas** Dist. is a very light form from the volcano Chiriqui with yellow colour at the end of the cell of the forewing and partly also at the base of the hindwing. Especially striking is the ♀ of this local form, in which the black median band of the hindwing is only indicated at the apex, and is sometimes entirely absent.

lycidice. **M. lycidice** Bates (34a). Smaller than *doryssus*. The forewing black with 3 yellow oblique bands, and also red-brown base and 2 red-brown spots at the inner angle. The hindwing has broader, black median band and before it an indistinct yellow longitudinal band. In the ♀ the black band is proximally incomplete. **eurydice.** In Central America, from Costa Rica to Honduras. — **eurydice** Hsch. is a similar form from Peru. The black marking in the disc of the forewing is reduced. The yellow subapical spot is prolonged into a band. The median band is narrower and more strongly dentate. The hindwing has a broad yellow longitudinal band and in the ♀ also the black macular band is complete. Antenna yellow-brown with dark base, in *lycidice* dark with yellowish club. — **doryssides** Stgr. is very similar to the preceding, but has no yellow longitudinal band in the hindwing and the spots in the disc of the forewing are brownish yellow. — **ovata** Dist., from Costa Rica, has broader and more roundish wings than *lycidice*. The macular bands of the forewing are narrower. The black longitudinal band of the hindwing is only present in the apex and the yellow marking before it is entirely absent. — In **isthmia** Bates (34b), from Panama and Costa Rica, the black colour occupies almost the whole of the forewing. The yellow median band is broken up into 2 spots. The black median band of the hindwing is very broad; yellow colour is absent. In the ♀ the median band is only indicated by a spot before the apex. — In a form from Honduras, which I call **arcana** form. nov., the hindwing has a broad yellow longitudinal band and also in the ♀ a complete black band behind it. — **californica** Reak. In this form from California the yellow spot on the discocellular of the forewing is said to be much narrower than in *isthmia*; behind the end of the cell a yellow band runs from the costal to the hindmargin.

mantineus. **M. mantineus** Hew. (34c) is a species very different from the preceding forms, which is distinguished by the almost complete absence of red-brown, even on the hindwing, and by the absence of the yellow subapical spot in the forewing. The forewing has only one red-brown spot at the inner angle and the hindwing a fine red-brown line before the distal margin. In addition to the yellow median line the forewing has 2 yellow spots and a streak on the median vein. The hindwing has a yellow longitudinal band. This interesting species, which recalls *Heliconius nattereri*, occurs only on the western slopes of the Andes in Ecuador, but is not rare.

franisi. **M. franisi** Reak. (33f) and the two following forms are nearly allied to *polymnia caucaënsis*. The ground-colour of *franisi* is reddish yellow-brown. The large yellow median spot in *caucaënsis* is here separated by a black macular band into 2 parts, of which the proximal one is partly yellow-brown. — In the form **peruana** Weym. the median band of the forewing is confluent with the distal margin; hence there remains of the yellow-brown ground-colour only a longitudinal band pointed towards the apex in the otherwise black-brown wing. **menapis.** — In the form **menapis** Hew. (33f) the black colour is still further increased, so that often only 2 small red-brown spots at the base of each wing remain. Almost all transitions between the 3 forms are found. They fly in Colombia, especially in the Cauca Valley.

elisa. **M. elisa** Guér. has the forewing similar to that of *isthmia*; the two yellow spots at the end of the cell of the forewing (the remains of the oblique band) are here still further reduced and are placed near to the costal resp. distal margin. On the other hand the two spots in the disc are enlarged. The zigzag band of the hindwing and the distal-marginal band are narrow. On the Upper Amazon and its tributaries in Ecuador, Peru **meneceles.** and Bolivia. — **meneceles** Hew. is a form from the Amazon with small yellow spots in the forewing and a small red-brown spot below the yellow one near the inner angle. The hindwing has only the beginning of the median band in the apical area. — In **ocona** Druce (= *vilcanota* Rüb.) (34b) the ground-colour in the ♂ is lighter yellow-brown. The yellow spots and the costal margin of the hindwing are semitransparent. Between the two oblong yellow spots at the end of the cell and the distal margin is placed another oblong yellow spot, so that here the usual oblique band is restored. The typical specimens come from the Upper Amazon, from Peru. At the Upper Napo in Ecuador the form is similar to *elisa*, except that in the forewing the yellow double spot of *ocona* is still present.

In the following forms the two proximal yellow spots of the forewing are united into a broad oblique band; the median band is only indicated by a few dots or is entirely absent.

M. macrinus Hew. (= ♀ *numerianus* Fldr.) (34b) has mostly 3 oblong yellow spots in the black apical third of the forewing as a remnant of the oblique band at the end of the cell. Between the median and its first branch is generally placed another, triangular black spot, especially in the ♂. The latter has moreover in the disc of the hindwing above a black longitudinal band, which is indicated beneath and in the ♀ only at the apex, or the black band is entirely absent beneath also. This species is deceptively similar to *Heliconius metaphorus*, with which it also occurs together. The examples from Colombia are distinguished by large black spots in the basal part of the forewing and broad black longitudinal band on the hindwing; those from Panama and Costa Rica have narrower wings, spots and bands. The specimens from Ecuador on the other hand have a bright yellow oblique band and small yellow spots in the forewing; the black spot at the median is mostly absent.

M. nessaea Hbn. (34b) differs from *macrinus* in the yellow longitudinal band of the hindwing and the two yellow dots at the end of the cell and the distal margin of the forewing. The species is especially common in Central Brazil. — **sulphurescens** Hsch., from Bahia in Brazil, forms the transition to the following subspecies. It differs from *nessaea* in the absence of the two yellow median dots; from *lysinnia* in the yellow instead of white subapical spot. — **lysinnia** F. (34b) is distinguished from *nessaea* by the white subapical spot and the absence of the yellow median dots in the forewing. — In ab. **albescens** Hsch. there is a white triangular spot at the distal margin of the forewing and on the under surface the subapical spot is surrounded by a white macular band, which shows through above. — The larva of *lysinnia* is blue-grey with white tubercles and black stigmata. Pupa shiny gold-yellow, with a silver gloss on the ventral side, and with black dots and lines. — *lysinnia* is one of the commonest species of *Mechanitis* and flies principally in Central and South Brazil.

13. Genus: **Aprotopos** Kirby.

Aprotopos is distinguished from the very similar *Thyridia*, as *Mechanitis* from *Melinaea*, by the aborted forelegs, from *Mechanitis* by the shorter cell. The species of this genus may be recognised superficially by 1—2 red-brown dots at the base of the forewing.

The few species have mostly a wide distribution, but are almost everywhere only taken singly.

A. melantho Bates (34c). This Central American species differs from all the others in the intense colouring of the wings. The normally vitreous spots of the forewing are almost entirely covered with black. The hindwing is dark red-brown with black distal margin and spot at the end of the cell. — In a form from the volcano Chiriqui, which I call **randolis** *form. nov.*, the whole apex of the hindwing as far as the end of the cell is black-brown except for a small red-brown streak.

A. aedesia Dbl. & Hew. (34c) has the same scheme of markings as *melantho*, but the vitreous spots of the forewing are much larger and especially at the base yellow-brown. The disc of the hindwing is likewise light yellow-brown, not so red-brown as in the figure. The black spot at the end of the cell is connected with the costal margin. Especially in Colombia and Venezuela.

A. ceto Fldr. (= *colombiana* Godm. & Salv.). This rare species has the markings as in *psidii*, on the other hand a brownish ground-colour similar to *aedesia*. Colombia.

A. psidii L. (34c). The similarity of this species to *Thyridia confusa* has been already mentioned under the latter. It occurs in Guiana and on the Lower and Upper Amazon, to the Andes of Peru and Ecuador. Specimens from the first named districts have broader black margins and bands; those from Ecuador and Peru have been designated **ino** by FELDER.

A. hippodamia F. (= *pytho* Fldr.), from Central and Southern Brazil, is a very similar, but smaller species with broader bands on the forewing and narrower ones on the hindwing. — **pallida** Godm. & Salv. is a form with brownish vitreous spots, similar to *ceto*; in Central Brazil.

14. Genus: **Callithomia** Bates.

In the species of this genus not the lower discocellular but the middle one is angled. The cell is long and extends almost to the margin. They are mostly medium-sized species, which occur especially in the north-west of South America and also in Central America.

C. hezia Hew. (36b) has very broad wings and strongly recalls *Hirsutis pinthias* in the marking. There occur here as there also the corresponding varieties, in which a yellow macular band is present on the hindwing. *hezias* is the commonest form, from Central America, with black-brown, yellow-spotted forewing and red-brown hindwing with dark apex. — **hedila** Godm. & Salv. is a form from Guatemala with larger, partly

confluent yellow spots in the forewing. On the hindwing the black marking is broader and occupies nearly half the wing. — In *tridactyla* Dew. (36 b), from Colombia, there is a yellow macular band behind the discocellular of the hindwing, similar to that of *Hirsutis hecalesina*, and the base of the hindwing is black-brown.

phagesia. **C. phagesia** Hew. (36a), from Ecuador, has similar markings; at the base of the forewing there is a red-brown stripe, and the spots are larger and dirty white. In the hindwing the area before the apex is transparent whitish.

megaleas. **C. megaleas** Godm. & Salv., from Panama, is said to have in the forewing a red-brown base, 6 yellow submarginal spots and a yellow oblique band. The hindwing is red-brown with narrow black distal margin.

schulzi. **C. schulzi** Hsch. (36 b), from the Lower Amazon, has large yellow spots in the forewing, and the basal third red-brown. The hindwing has a median macular longitudinal band and large marginal teeth with yellow dots. In the ♂ the anterior half of the hindwing is transparent yellowish, in the ♀ red-brown. — In *alexirrhoë* Bates, from the Upper Amazon, near S. Paulo, the ground-colour is darker red-brown. The hindwing is not yellowish-transparent and the marginal dots are white. — **zeuxippe** Bates, from the Cupari (a tributary of the Amazon), has at the base of the forewing broad black margins. The apex is dark brown, with 3 yellowish spots and red-brown margins. — **thornax** Bates, from the Upper Amazon, near Tabatinga, has blackish apex with 4 yellowish spots and 6 brownish marginal spots. Hindwing with black teeth at the distal margin. — **butes** Godm. & Salv., from the lower Napo in Ecuador, is said to be similar to the preceding, but to have yellowish spots in the apex of the forewing and a broad, dentate black distal margin to the hindwing. — *philomela*. **philomela** Godm. & Salv., from Colombia, is said to approximate to *zeuxippe*, but to have narrower forewing, whilst the hindwing is semitransparent with black apex. The black macular band is placed nearer to the lower end of the cell. — The last 5 forms all intergrade more or less with one another, being apparently local forms still in course of development, so that it is very difficult to refer the transitional specimens to the individual forms. — On the Ucayali in Peru there is further a peculiar form, which I call **infuscata** form. nov. Here the forewing is yellow-brown with dark margins and in addition to the black median spot in the cell a roundish spot is placed in the end of the cell and 3–4 oblong spots in the apical third. The hindwing has 2 macular bands, in the disc and at the anal angle. This form recalls *Hyposcada rezia*.

hydra. **C. hydra** Fldr. (= *valera* Stgr.), from Venezuela, has blackish forewing with 3 yellow macular bands and brownish base. The hindwing is red-brown with dark distal margin. — In the somewhat larger *beronilla* Hew. (36 c), from Colombia and Ecuador, the central macular band is absent and the proximal one is not divided by a triangular black spot, as in *hydra*. — The nearly allied **panamensis** Godm. & Salv., from Panama, has a broad yellow oblique band, in which several roundish black spots are placed. The hindwing is broadly black at the apex and distal margin.

procne. **C. procne** Godm. & Salv., from Colombia, is said to have the apex of the forewing black as far as the end of the cell, and a broad yellow oblique band, which is divided by a red-brown stripe over the 2. median vein.

villula. **C. villula** Hew. (36 c). This interesting species has exactly the markings and colouring of certain *Ceratinia*, e. g. *praxilla* and *ocna*; but it may be recognised by the angled middle discocellular, resp. not angled lower one. On the under surface the hindwing has a white double spot at the costal margin near the middle and 6 white distal-marginal dots. Colombia.

15. Genus: **Ceratinia** Hbn.

This genus contains numerous species of very varied appearance, mostly of medium size. It may be recognised by the very long cell of the forewing (especially in the ♂) with angled lower discocellular, yet there are differences in the neurulation even in specimens of the same species. The species of this genus occur from Mexico to Brazil and Argentina. Many forms of the plains are at times very common, whilst others from the valleys of the Andes are quite local and rare. The wing-pattern and colouring in *Ceratinia* is very varied. Although the *Lycorea*-habitus predominates, yet there are also many forms with vitreous or otherwise marked wings, so that similarities to almost all the markings which occur in other Ithomiid-genera may be found.

polymnides. **C. polymnides** Hsch. The marking is similar to that of *Mechanitis polymnia*, with broad yellow median band, without subapical spot on the forewing and with 2 black-brown zigzag bands in the disc and at the anal angle of the hindwing. Upper and lower surface are without distal-marginal dots. In Central Colombia. — In **menans** Hsch., from the same localities, the forewing has moreover 6 yellow distal-marginal dots, which are largest in the apex. In the ♂ the costal margin of the hindwing is lighter and transparent.

C. amica Weym., from Colombia and Ecuador, is similar to *polymnides*, but has only 3 black dots *amica*. in the disc of the hindwing and a narrow black distal margin. The yellow transverse band of the hindwing is only half as broad. — The similar **baana** Druce, from Peru, is said to be distinguished among other details *baana*. by white marginal dots on the under surface, which are wanting in *amica*.

C. mansuetus Hew., from the Upper Amazon, has similar markings to *moebiusi* following hereafter. *mansuetus*. The wings are shorter and more rounded. The forewing has in addition 3 yellow dots at the distal margin and the hindwing 4 black spots in the disc, whilst the narrow distal border is strongly dentate at the inner angle. In specimens from Peru the yellow dots on the forewing are absent. — **moebiusi** Hsch. (34 d) has a broad *moebiusi*. yellow oblique band in the forewing. At the inner angle of the hindwing there is a large black band-spot and at the end of the cell 2 more isolated spots.

C. honesta Weym. (34 d) is a similar species with differently formed oblique band and rounded black *honesta*. spot in the hindwing. Of the two black spots at the end of the cell of the forewing the one at the costal margin is here the longer, in *moebiusi* just the reverse is the case. This species flies on the eastern slopes of the Andes of Ecuador, whilst the local form **bicolora** Hsch., in which the yellow oblique band is absent, occurs still *bicolora*. further east, on the upper Rio Napo. The latter resembles, besides the larger *Melinaea mothone* and *Mechanitis deceptus*, especially *Hyposcada fallax* and *Ceratinia semifulva*. *fallax* is recognised at once by the large black antennae and the short cell of the hindwing; *semifulva*, in addition to its smaller size, by the dark base of the forewing and only 2 black spots at the end of the cell.

C. mamercus Hew. is similar to *mansuetus*, but smaller, with broader, short, distally convex yellow *mamercus*. oblique band. The black median band of the hindwing and the distal border, which is broad at the inner angle, are united at the inner margin. In some specimens median band and distal border are joined into a large patch. Flies on the eastern slopes of the Andes of Ecuador. — Thence comes also the similar **aemilia** Hew., *aemilia*. with narrower oblique band and yellow marginal spots in the apex of the forewing. At the inner angle of the hindwing is placed a distally divided black spot.

C. manaos Bates is similar to *mamercus* and *rowena*. Yellow band of the forewing extending into the *manaos*. cell. Hindwing with 2 black macular bands. From the lower Rio Negro. — **rowena** Hew. is a smaller form *rowena*. from Colombia with narrow yellow oblique band, double spot at the end of the cell, long wedge-spot and broad streak at the base of the forewing, as well as large double spots at the inner angle of the hindwing. — In **achaea** *achaea*. Hew., from eastern Ecuador, which is of the same size, the oblique band is divided into 2 spots at the end of the cell and the inner angle of the forewing. The hindwing, including the costal margin, is for the most part black-brown, only the apex is red-brown. — **semifulva** Salv. (34 d) has already been mentioned under *bico-* *semifulva*. *lora*. It is the local form of *achaea* or a nearly allied species, without the yellow oblique band on the forewing. It occurs, like all the similar forms, in eastern Peru and Ecuador, together with **occulta** Hsch., which has *occulta*. 3 more yellow spots in the apex of the forewing and white distal-marginal dots on the under surface.

C. apollinis Stgr. (34 d) approximates to *aemilia*, but has larger yellow subapical spots in the forewing *apollinis*. and a large black spot at the inner angle of the hindwing. It flies on the Upper Amazon near Iquitos.

C. viola Hsch. (34 e) has a distally lobed yellow oblique band in the forewing, dark distal margin and *viola*. spot at the end of the cell of the hindwing. The ground-colour is dark brown-red. It flies on the Upper Amazon, together with the similarly coloured *Melinaea satevis* and *madeira*. — In the local form **boliviensis** *boliviensis*. Hsch. the ground-colour is lighter red-brown; the hindwing has a dark median band and broader distal margin. — **herbita** Weym., from Surinam, has a similar yellow oblique band, and on the hindwing the median band *herbita*. and distal margin dark.

In **C. catilla** Hew. (34 e) the apex is broadly black to the end of the cell, then follows proximally the *catilla*. yellow oblique band. The broad black distal margin of the hindwing is united at the apex with the median band. The ground-colour is dark red-brown. Bolivia.

C. cantobrica Hew. (34 e) has yellow spots at the apex and distal margin of the forewing and also a *cantobrica*. curved yellow macular band. The distal border of the hindwing is narrower. The ground-colour is red-brown. The habitat is Bolivia. — In the smaller **pamina** Hsch. the yellow spot is narrower and also proximally mar- *pamina*. gined with black. The yellow marginal dots are absent. This form comes from the frontier districts of Peru and Bolivia.

C. pyrippe Hpffr., from Peru, is a form with broad yellow oblique band in the forewing and narrow *pyrippe*. streak-like longitudinal band in the hindwing. — In **tenna** Hsch. (34 e) on the other hand the oblique band *tenna*. is narrow, the dark distal margin of the hindwing broader. Eastern Ecuador. — In **napona** Hsch., which *napona*. is the same size, the oblique band of the forewing is broken up into 2 spots; the two black basal spots are larger; the distal margins have yellow marginal dots. — In ab. **calva** Hsch., which also flies on the upper Napo, the *calva*. black longitudinal band in the disc of the hindwing is absent. In the ♂ the anterior third of the hindwing is semitransparent.

- nina*. **C. nina** Hsch. is larger than *napona* and has a complete undulate transverse band in the forewing; further 2 yellow spots near the end of the median. Bolivia. — In **callanga** Hsch. (34 e) the yellow oblique band and the spots at the end of the cell have assumed the red-brown ground-colour. There is sometimes, especially on the under surface, another red-brown oblique band in the apex of the forewing. This form occurs at the boundary of Peru and Bolivia near Yungas.
- fenestella*. **C. fenestella** Hew. (34 e) is a form similar to *nina*, with yellow oblique band and broader longitudinal band on the hindwing; from Venezuela. — **intermedia** Btlr., from eastern Colombia and Ecuador, has the oblique band as in *fenestella*; above yellow marginal dots, beneath white ones. Hindwing with abbreviated longitudinal band. — In **peruviana** Stgr., from Peru, the hindwing in the ♂ is transparently yellowish at the costal margin, in the ♀ the marginal spots are yellow beneath. — In the form **hemimelas** Stgr., from Chanchamayo, the distal border and the longitudinal band of the hindwing are merged into one patch. — The Central American form of *fenestella*, from Costa Rica, which I call **valora** form. nov., is larger and has very large, oblong yellow spots in the apex of the forewing. On the upperside of the hindwing the white marginal spots are absent.
- ninonia*. **C. ninonia** Hbn. (34 f) is a smaller species and occurs in typical examples chiefly in Guiana and on the Lower Amazon. The disc of both wings is transparent in the ♂, but on the hindwing more brownish than in the figure. The yellow transverse band of the forewing is very broad. The yellow marginal dots are rather large in this and the following forms. — BATES describes as **bari** a form from Tocantins and Tapajos, which is said to have a narrower hindwing and paler, yellow spots. — In the larger **completa** Hsch. (34 f), from the Upper Amazon, the yellow oblique band is only half as broad and does not extend into the cell. — In the form **maculata** Hsch., from the Lower Amazon, the band is divided into 2 yellow spots. This large local form has very broad wings and large yellow marginal dots. — In **latefasciata** Hsch. the black spots at the end of the cell of the forewing are small, hence the yellow oblique band is very broad. It flies on the Upper Amazon, whilst the similar **philidas** Godm. & Salv. has its habitat in Colombia. The latter has a much broader black median band on the hindwing and no yellow marginal dots on the upper surface of the hindwing.
- mutilla*. The very similar **C. mutilla** Hew. (34 f), from British Guiana, has a pale yellowish oblique band and in addition a red-brown spot towards the apex. The longitudinal band of the hindwing is mostly very broad. — In ab. **pellucida** Hsch. the black spots at the end of the cell and the distal margin of the forewing form a broad band; the longitudinal band of the hindwing, on the contrary, is narrower. This form flies together with the preceding.
- pellucida*. A similar form, from Venezuela, which I call **C. vallina** spec. nov., is larger and has very broad wings. The longitudinal band of the hindwing is narrow and placed very far distad, so that the semitransparent discal area becomes very large.
- vallina*. **C. granadensis** Hsch. stands rather isolated, only to some extent recalling *philidas*. The yellow oblique band is very broad and in it are placed at the end of the cell the two black spots, which are here very small, whilst the third in the end of the cell is very long and wedge-shaped. At the apex and again at the distal margin there are 2 white dots. The hindwing is as in *philidas*, with narrower black longitudinal band. In Central Colombia.
- granadensis*. **C. maenas** (Bang-H. i. l.) (34 f) has the pattern somewhat like that of *latefasciata*, but the yellow transverse band of the forewing and the yellow marginal dots are absent. It flies with the similarly coloured forms of other genera on the Upper Amazon.
- maenas*. **C. antonia** Hew. (34 g) has a yellow-brown ground-colour and different yellow macular band. The yellow marginal dots are very large, but smallest in the apex of the forewing. — In the similar **antonina** Stgr., from the Upper Amazon, it is just the reverse, the marginal dots are largest in the apex, moreover the macular band is much smaller, proximally edged with black. *antonia* from western Ecuador differs moreover in the longitudinal band of the hindwing, the spots of which are largest at the apex.
- antonia*. **C. fimbria** Hew., from Colombia, has a broad yellow oblique band on the forewing, which is divided by a black macular band, so that there is a large yellow patch at the inner angle. The marginal dots of both wings are white. — In the similar **nemea** Weym. (34 g), also from Colombia, the yellow band is narrower and differently formed. The hindwing is not transparent as in *fimbria*.
- fimbria*. **C. philetaera** Hew. (34 f) may be recognised by the large yellow median spot on the forewing and the broad black distal border of the hindwing. In the distal margin of the forewing and mostly also of the hindwing are placed yellow dots, among them 2 larger ones in the apex of the forewing. The habitat of this easily recognised species, which resembles *Melinaea idae*, is Colombia.
- philetaera*. **C. leprieuri** Feisth., from Cayenne, has similar hindwing, which is black also at the costal margin, and white marginal dots. The yellow median spot is distally rounded; the black spots at the end of the cell are joined rectangularly with the spot at the median.
- leprieuri*. **C. ignorata** Hsch. (34 f) has similar markings, but yellow marginal dots on the forewing, and the hindwing is red-brown, with black, yellow-dotted distal margin and black longitudinal band. This species flies

on the Upper Amazon. — In the local form *michaëlisi* Hsch., from the Lower Amazon, the yellow patch is *michaëlisi*. divided by a black oblique band from the discocellular to the inner angle.

C. cornelia Guér., from Bolivia, has a narrow yellow oblique band on the forewing and 4 yellow spots *cornelia*. in the broad black distal margin of the hindwing, as well as a black spot at the apex. — In the similar *sellana* *sellana*. Hsch. the oblique band is divided into 2 spots; the middle marginal dots are absent in the forewing. The distal margin of the hindwing is proximally widened into teeth.

C. fulminans Btlr. (34 g) has a narrow yellow oblique band, strongly angled distally. The black spot *fulminans*. at the end of the cell is proximally forked. The hindwing has a narrow distal border and a longitudinal band of 3 black spots in the disc. The ground-colour is light yellow-brown. — This form from Colombia is represented in eastern Ecuador by the dark red-brown *satura* Hsch. In this the yellow colour is wanting in the *satura*. end of the cell of the forewing and at the apex of the hindwing.

C. angelina Hsch. (34 g), from the Ucayali (tributary of the Upper Amazon) has the pattern similar *angelina*. to that of *fulminans*. But the yellow marginal band and the distal-marginal dots are absent. The apex is more narrowly black, on the other hand the macular band in the disc of the hindwing is much broader, partly confluent with the dentate distal margin.

In a smaller species, **C. soror** Srka., which is confusingly like *Melinæa lucifer*, the oblique band is like- *soror*. wise absent. The apex of the forewing is, however, more broadly black and the yellow spots in it are merged into one large one. In the hindwing longitudinal band and distal margin form a large black patch, as in *Melinæa lucifer*. This interesting species comes from Pebas on the Upper Amazon.

The description of **C. acceptabilis** Weeks, from Bolivia, has unfortunately not been obtainable.

acceptabilis.
anastasia.
anastasina.

The large, broad-winged **C. anastasia** Bates has the pattern similar to *anastasina* Stgr. (35 a), but behind the end of the cell of the forewing another yellow zigzag band, like that of *fulminans*, and 7 yellow marginal dots. *anastasia* flies in the damp primeval forests near Ega on the Upper Amazon, whilst *anastasina* occurs further up at the foot of the Andes in Peru. — *castanea* Btlr., from Rio Juruá, is a darker form of *castanea*. *anastasia*, in which the yellow oblique band reaches to the hinder angle of the forewing. These 3 forms closely resemble *Melinæa maëlus* (= *pardalis* Bates) resp. *cydon*.

C. porsenna Srka. (= *amabilis* Stgr.) is similar to *anastasius* in size and markings. The yellow apical *porsenna*. spots in the forewing are much larger and proximally edged with black. On the hindwing the median band and the dark distal margin are united into a large patch. — This form flies, like the similar *soror*, on the Upper Amazon near Pebas.

In **C. fluonia** Hew. and the allied forms the anterior half of the yellow oblique band of the forewing *fluonia*. is curved distad, as may be seen in the figure of *berna* (34 g). *fluonia* has a four-branched, yellow macular band, which enters the cell and nearly reaches the inner margin. The black double spot at the end of the cell has also a corresponding curved projection towards the apex, as in *pardalina* (34 g). The hindwing is like that of *berna*. *fluonia* flies on the Upper Amazon, whilst the local form *berna* Hsch. (34 g) comes from *berna*. the upper Napo in Ecuador. The latter has instead of the large macular band in the forewing only 2 oblong yellow spots in the black apical area.

C. pardalina Hpffr. has a yellow oblique band in the forewing. The aberration figured (34 g) was des- *pardalina*. cribed by DRUCE as *tigrina*. In the latter only a yellow spot at the discocellular remains of the band. Other- *tigrina*. wise the marking and colouring is similar in both forms. Of the black colour in the apex of the forewing only marginal dots remain in *fluonia*, whilst in the hindwing the black median band and the distal border are widened. The species resembles the respective local forms of *anastasia* and *Melinæa maëlus*. Both forms fly on the Upper Amazon in Peru; *tigrina* may, however, occur further up. — *pantherina* Stgr., likewise from *pantherina*. the Upper Amazon, is an intermediate form between *fluonia* and *pardalina*, in which red-brown spots appear in the apex of the forewing. The black median band of the hindwing is as in *fluonia*.

C. thea Hew. recalls *catilla* (34 e), but the yellow median spot is rounder and does not extend so far *thea*. to the hinder angle. In a smaller form, which STAUDINGER named *theatina* (i. l.) (35 a), the yellow spot *theatina*. is likewise rounder than in the figure. This form is, however, considerably smaller, has lighter ground-colour, and at the end of the cell of the forewing there are only 2 small, black spots, whilst in *thea* a large black spot extends into the yellow and is joined to the black costal and distal margin. The hindwing has in both forms a black distal border and median band, which sometimes touch at the apex. They fly on the Upper Amazon and its tributaries.

C. xanthostola Bates (35 a) stands completely isolated. The hindwing is much shorter than the fore- *xanthostola*. wing, which is not brought out clearly in the figure. In this the species recalls some *Napeogenes*-species. Very striking moreover is the absence of the median band on the upper surface of the hindwing, as is also the case in *Mechanitis macrinus*. In an aberration, which I have described as *desmora* Hsch., the black spot at the *desmora*. base of the forewing above is absent and the black bordering at the proximal side of the yellow spot is much narrower. Both forms fly on the Middle Amazon.

- dionaea*. **C. dionaea** Hew. I only know in typical specimens from Central America (Honduras, Guatemala), on the other hand in Venezuela a local form occurs which I designate **fraterna** *form. nov.* (35 a). In *dionaea* there is proximally to the yellow oblique band a larger yellow spot which is joined to the red-brown basal part. In *fraterna* there is instead only a small spot which is mostly confluent with the oblique band, but is proximally edged with black. Moreover, in *fraterna* the yellow colouring is brownish and the distal-marginal dots are smaller. In *Mechanitis* there are 2 corresponding forms: *doryssus* from Central America and *veritabilis* from Venezuela. — *limpida* Hsch. is a peculiar form of *fraterna*, in which the yellow bands and spots are very broad and transparent; a stripe at the costal margin of the hindwing is of the same colour. This interesting local form recalls *Mechanitis franis* and flies like the latter in the Cauca Valley in Colombia.
- mergelena*. In **C. mergelena** Hew. (35 a), from Colombia, the median band of the hindwing is reduced to a black spot at the apex, which is connected with the broad black distal border. At the base of the forewing there is further a proximal yellow oblique band, which is divided by a large, triangular black spot. — In **megalogopolis** Fldr., likewise from Colombia, this black spot is absent, so that a broad yellow oblique band is formed, as in *Mechanitis macrinus*. The yellow spots at the end of the cell on the other hand are small, and also the white marginal dots on the hindwing.
- callispila*. **C. callispila** Bates (35 a), from Costa Rica, has a black-brown forewing with numerous yellow spots and red-brown base. The hindwing is red-brown with dark distal margin, blackish apex and spot at the end of the cell. — In **cleis** Bates, from Panama, the yellow spots in the disc of the forewing are much smaller. The distal margin of the hindwing and the spot at the end of the cell are united into a large patch in the apical third. — As **mylassa** DRUCE describes another form, from Veragua, with broad black apex and distal margin to the hindwing, which, however, are not confluent with the spot at the discocellular. — **leucania** Bates, from Panama, is similar to *callispila*, but has white spots in the forewing which form an oblique band at the end of the cell. The hindwing has dark distal margin and a narrow longitudinal band.
- decumana*. **C. decumana** Godm. & Salv. (= *centralis* Stgr.) (35 b). This fine, large species and especially the local form **excelsa** Fldr. recall the similar *Ituna lamirus* and *Olyras montagui*. The markings resemble those of *callispila*; the yellow spots are larger and transparent. On the hindwing the spot at the end of the cell is absent. In *decumana* the base of the forewing is black-brown, whilst *excelsa* has a red-brown stripe along the median vein. Moreover, the hindwing on the upper surface of *decumana* is uniformly red-brown in the disc, in *excelsa* a transparent oblique band runs from the apex to the inner margin. *decumana* flies in Panama and Costa Rica, whilst *excelsa* comes from Colombia. — STICHEL erected the genus *Oreogenes* for these two forms, but the characters in the neurulation are not constant.
- vallonia*. With **C. vallonia** Hew. (35 b) we come now to a group which is distinguished by a broad, transparent band in both fore- and hindwing. The forms are all indigenous to eastern South America, especially Brazil. In *vallonia* the yellow oblique band of the forewing forms a semicircle. In the cell is placed a triangular black spot. The band of the hindwing is transparent red-brown. The antennae are yellowish, with dark base. The species occurs on the Upper Amazon and in Guiana. — In the somewhat larger **daëta** Bdv. and the following forms the band of the hindwing is yellow, antennae dark with yellow club. The apex of the forewing in *daëta* is broadly black with 3 large white dots. At the hinder angle is placed a red-brown spot, whilst in the very similar, but larger **euryanessa** Fldr. (35 b) this angle is black. The latter form has very delicate, transparent colouring, even in the apex of the forewing. The black oblique band before the end of the cell of the forewing is posteriorly broad and dentate, in *daëta* posteriorly reduced. Finally in *daëta* and the following forms the base of the hindwing beneath is yellow, but in *euryanessa* red-brown. The two forms occur together in numbers in central and southern Brazil in the dense virgin forests. — Larva and pupa of *euryanessa* according to SEITZ are stout. The pupa is rounded, yellow-brown, darker at the wings, adorned all over with small black wavy markings.
- daëtina*. — **daëtina** Weym. is a very rare form of *daëta* with dark mahogany-brown ground-colour and broad black bands and margins. In addition to the two yellow bands there is a yellow spot on the discocellular of the forewing. — As *evanescens*, **evanescens** (= *melphis* Hbn.) I designate a very light, transparent form of *daëta*. Not only the very broad, light yellow band of the hindwing, but also the whole disc of the forewing is transparent yellowish. The red-brown colour is confined to the base and a spot at the hinder angle of the forewing and also a narrow stripe at the distal margin of the hindwing. — **laphria** Dbl. (35 b) is another very similar species from central Brazil. Size and markings as *daëta*, but not transparent. The white spots in the apex of the forewing smaller. Across the end of the median a further black streak. The eggs of *laphria* are laid in clusters on the leaves of a Solanaceae. The young larvae are yellow-brown with dark head; later they have 3 dark dorsal stripes which are connected by transverse lines. The pupa is short and stout with metallic surfaces at the sides. The pupal stage lasts about 11 days.
- melphis*. **C. melphis** Godt., from the Antilles, which is unknown to me in nature, is said to have black forewing with 3 pale yellow-red bands and 3 white dots in the apex. The hindwing is yellow-red with black costal and distal margins, and also a median band, which does not reach the distal margin.

As *C. mysotis* spec. nov. I designate a species from Venezuela similar to *evanescens*, with shorter wings, *mysotis*. in which the red-brown colouring is absent except for the spot at the hinder angle. The hindmargin of the forewing is broadly blackish to the median. Both wings have white marginal dots.

C. fiammetta Hew. is a peculiar, rare species from South Brazil of the size and pattern of *laphria*. On *fiammetta*. the forewing the red-brown colour only extends from the base to $\frac{1}{3}$, behind it there are 2 transparent spots apically before the yellowish band. On the hindwing the red-brown is entirely absent; this is transparently yellowish, with broad black distal margin and small white marginal dots.

C. metella Hpffr. (35 b, c) (= *alexia* Druce), from eastern Peru, has in the ♂ transparent yellowish *metella*. wings with black margins and a half-band at the end of the cell of the forewing. The base of the forewing and the proximal half of the hindwing are reddish yellow-brown. Both wings have small white distal-marginal dots. In the ♀ the wings are scarcely at all transparent, much more brightly coloured, with broader, black margins. The disc of the hindwing is red-brown. — In the similar *oulita* Hew. the base of the forewing is *oulita*. blackish, and the black margins are broader. It occurs further south at the boundary of Peru and Bolivia. — *trimaculata* Weym. is a form from Colombia with very broad black costal and distal margins to the hind-*trimaculata*. wing, so that in the ♀ only a smaller, yellow-red spot is present at the inner angle.

The ♂ of *C. norella* Hew. has a deep black basal half to the forewing, in which a yellow spot is placed *norella*. at the end of the cell. In the ♀ the whole forewing is black except for the yellow spots in the disc and the white marginal dots. The form occurs only in the valleys of the Andes of Ecuador, south-east of Cuenca. — In the allied *norellana* Hsch., from the upper valley of the Napo in Ecuador, the base of the hindwing *norellana*. is not yellowish and the reddish colour only extends to the end of the cell. The part between this and the broad distal margin is transparent blackish. This rare form occurs in open places in the primeval forests, where it is fond of hovering round single trees at a few metres from the ground or resting upon projecting branches. — *nora* Hsch. is another allied form from Peru. Here the forewing is as in *norellana*, the base trans- *nora*. parent. The black spot at the end of the cell is isolated. The hindwing is only reddish at the anal angle, as in *lurida* (35 c), the distal half is transparent yellowish.

C. lurida Btlr. (35 c) is marked like *nora*, but has white dusting instead of the yellow colour in the disc *lurida*. of the forewing and at the end of the cell of the hindwing; also the underside of the abdomen is whitish, in the preceding form yellow. — The smaller *tricolor* Salv. has similar markings to *oulita* Hew., but also white *tricolor*. instead of yellow colour. In the ♀ there is an oblong white patch at the end of the cell of the hindwing. — Whilst in *tricolor* the black spot at the end of the cell of the forewing is broadly connected with the costal margin, in an otherwise very similar form, which I call *floreus* form. nov., there is only a narrow, isolated streak at *floreus*. the end of the cell. — The last three forms are found at the boundary of Peru and Bolivia.

In the following species the wings are almost entirely vitreous.

Some, as *C. ocna* H.-Schäff. (35 c), have still a small red-yellow spot at the anal angle of the hindwing. *ocna*. The base of the wing is yellowish. This species flies singly in eastern Colombia and Ecuador. — *adelinda* *adelinda*. Hew., from Ecuador, is a very similar form, with broader, black distal margin, without white marginal dots on the upper surface.

C. praxilla Hew. is an allied, somewhat larger species from eastern Ecuador, without yellow colour *praxilla*. at the anal angle of the hindwing. In contrast to *ocna* and most of the allied forms; *praxilla*, *coeno*, etc., have black antenna and a white spot at the base of the hindwing beneath, the former a yellow streak and yellow club to the antenna.

C. guttata Weym. is a form of *coeno* Hew. (35 d). It has a red-yellow spot at the anal angle of the *guttata*. hindwing. *coeno* itself, from Colombia and Venezuela, has the basal half of the hindwing dusted with yellow. *coeno*. In the ♂ the black distal margins are narrower. — ab. *latilimbata* Weym. is a form of *coeno* with broad black *latilimbata*. margins and large white marginal dots, from Colombia.

In *C. frater* Salv., from Peru, the wings are dusted with whitish, and at the anal angle is placed a smaller *frater*. yellow patch.

In *C. cana* Hsch., from Colombia, the wings are dusted with whitish, the yellow patch is absent. On *cana*. the other hand a blackish band runs across the middle of the cell of the forewing.

C. statilla Hew. (35 c) is distinguished from the very similar *frater* by the yellow club of the antenna *statilla*. and yellow underside of the abdomen, which is grey in *frater*. The end of the cell of the forewing is without markings, whilst in *atagalpa* Hsch. a blackish band is placed across the end of the cell of the forewing. Both *atagalpa*. forms come from eastern Peru.

C. antea Hew. (35 d), from Ecuador, the largest species of the genus, has colourless wings with broad *antea*. black margins and small, white distal-marginal dots. The club of the antenna, base of the hindwing beneath and underside of the abdomen are yellow. On the high bank of the upper Pastaza this interesting species was

found rather commonly among immense trees, together with the very similar *Napeogenes glycera* and *lycora*, *Ithomia linda*, *Hypoleria coenina*, *Threnodes coenoides*, etc.

eupompe. The last species of this extensive genus, **C. eupompe** Geyer (= *phlysto* Fldr.) (35 d), from South Brazil, stands quite isolated, much more recalling certain species of the genera *Napeogenes*, *Ithomia* and *Pteronymia*. The wings are short, transparent yellowish, with black margins and a half-band across the end of the cell of the forewing; on the under surface with rows of red-brown spots and whitish double spots. Antenna black, collar red-brown. — Larva according to W. MÜLLER rather transparent, above grey-green, head yellow, later black. Pupa transparent green, with shiny gold lines and black spots.

16. Genus: **Heteroscada** Schatz.

This genus contains only 2 small, yellowish forms, which occur in Brazil. The middle discocellular of the hindwing is weakly curved proximally, the upper one in the ♂ is long.

gazorla. **H. gazorla** Godt. (= *yanina* Hew.) (36 d). This pretty little species is very similar to *Pteronymia hemixanthe* (40 d). The collar is red-brown, the abdomen beneath yellow. The wings are dusted with yellow to beyond the end of the cell and have dark margins.

fenella. The somewhat larger **H. fenella** Hew. has broader borders, a broader half-band across the end of the cell of the forewing and a red-yellow spot at the base. It closely resembles *Napeogenes xanthone*. — Both species fly in Central Brazil.

17. Genus: **Napeogenes** Bates.

In this extensive genus there are many forms whose pattern and colouring recur in certain *Ithomias*, so that they can only be recognized by the neururation. All the *Napeogenes* may be distinguished from the similar species of other genera by the non-angled discocellular, the long cell and the apparently 5-branched median in the hindwing. — The species are scattered over the whole Neotropical region, mostly mixed with the corresponding species of other genera, but are usually rare, whilst the more vigorous *Ithomias* are met with in large numbers.

peridia, *hemimelaena*. **N. peridia** Hew. (35 d), from Colombia, has similar markings to *Callithomia tridactyla* and *Hirsutis hecalesina*; the hindwing is, however, distinguished by large yellow distal-marginal dots. — In **hemimelaena** Godm. & Salv., from Panama, the yellow spots at the end of the cell of the forewing are united into one large one, as in *iquitensis* (35 d). The yellow spots at the apex and distal margin of the hindwing on the contrary are very small and the apical half consequently much more strongly coloured with black.

iquitensis. **N. iquitensis** Stgr. (35 d), from the Upper Amazon, has in the black apical half of the forewing a broad, curved, yellow band; in the red-brown basal half 2 black spots and on the red-brown hindwing a black macular band and dentate distal margin.

amara. **N. amara** Godm. (35 d), from Central America, is smaller than *peridia* and has in the apical part of the forewing fewer, but larger, yellow spots, and at the base a red-brown spot. The marginal dots are smaller and white. At the apex of the hindwing are placed 2 indistinct yellowish spots. — In the somewhat larger *tolosa* Hew. (35 e) the ground-colour of the hindwing and the base of the forewing are lighter yellow-brown. The yellow spots of the forewing are larger, the distal border of the hindwing narrower. *tolosa* inhabits Mexico and northern Central America.

olyrina. The interesting and rare **N. olyrina** Hsch. (35 e), from Bolivia, recalls *Ceratinia excelsa* and *Olyras montagui*. The black forewing has large whitish vitreous spots, the red-brown hindwing bears in addition to the broad, dark marginal band a hyaline oblique band in the apical half, as in *excelsa*.

larina. **N. larina** Hew. (35 e), from eastern Colombia, has white spots on the forewing; of the marginal spots those in the apex are larger; the base of the forewing is red-brown. In the disc of the hindwing are placed 3 isolated black spots. *Ithomia candescens* is very similar.

aethra. **N. aethra** Hew. (35 e), from the upper Napo in Ecuador, has larger, band-like, yellow spots in the disc of the forewing and indistinct yellow marginal dots. The hindwing is dark-margined, with 4 black spots in the disc.

duessa. **N. duessa** Hew. (35 e) may be recognised by the chestnut-brown ground-colour and the two black half-bands at the apex of the hindwing. The forewing has a yellow median spot with black dot and a dark brown base. This peculiar species flies on the Upper Amazon in Peru and Ecuador.

quadrilis. In **N. quadrilis** Hsch., from the Upper Napo, the ground-colour is yellow-brown and the yellow median spot of the forewing is prolonged, forming an oblique band. In the dark-margined hindwing a large black-brown spot is placed at the inner angle.

The following 5 forms are all very nearly allied; they have the usual ground-colour with black apical half and black cell-spot on the forewing, also dark dentate marginal band on the hindwing and 3—5 black spots in the disc. — **N. terastis** Hsch. (35 e) has a yellow median and subapical band on the forewing, — *terastis*. It is the form from the Lower Amazon, whilst in **zurippa** Hew., from Bolivia, the median band is broken up into 2—3 spots. — **otaxes** Godm., which, like the two following forms, occurs in Peru, has a pale, yellowish median band and in the apex 2 dots of the same colour. — **pyrrho** Druce has still the yellow subapical band, but the median band is absent. — In **deucalion** Hsch. the subapical band is also absent except for 2 yellow dots.

N. hygia Godm., from Surinam, which is unknown to me in nature, is said to resemble *Mechanitis hygia*.

N. stella Hew. (35 f). In this small species and its local forms from eastern Colombia and Ecuador the blackish colour in the distal half of both wings is almost entirely suppressed by the yellowish vitreous spots. *Calloleria jolaia* has a very similar pattern and can only be distinguished by the neurulation. — In the somewhat larger **glabra** Godm., from Colombia, the wings are still more transparent and the marginal dots yellow. The inner margin of the forewing is black. — **aster** Godm., from Ecuador, has darker wings and smaller marginal dots. — In the similar **decora** Godm. the margins of both wings are much broader. The forewing has a dark streak through the cell.

N. larilla Hew. (35 f), from Ecuador, has vitreous wings with dentate, dark distal borders and a spot at the end of the cell on each wing. In the ♀ the wings are broader, the margin of the forewing red-brown and the white marginal dots on the hindwing much larger. This rare species recalls *Velamysta pardalis* and *Dismenitis theudelinda*, with which it occurs in the mountain forests up to heights of 2500 m.

N. cranto Fldr. (35 f), from Colombia, has the margins and a half-band across the end of the cell of the forewing dark brown. The base of the forewing and the hindwing are dusted with yellow. — The similar **paedaretus** Godm. & Salv., from Costa Rica, is more brightly coloured and has yellow-brown veins, also at the apex and the dark costal margin of the forewing 2 oblong yellow spots. In the ♀ the base of the forewing is dark and the hindwing is yellow-brown.

In the smaller **N. harbona** Hew. (35 f), from Ecuador, the wings are colourless, the margins black above and red-brown beneath, with indistinct, white marginal dots.

N. apulia Hew. (35 f), from Colombia, has a pattern like *Ceratinia oena*, with red-brown spots at the inner angle of the hindwing. — In the somewhat larger **nausica** Weym., from Ecuador, the distal border of the forewing is broader, the inner border narrower. The red-yellow spot at the inner angle does not reach the base.

N. lycora Hew. (35 g), from eastern Ecuador, is similar to *apulia*, but the red-yellow colour at the inner angle of the hindwing is absent; the base of the latter is slightly yellowish. Moreover, the club of the antenna is yellow.

N. glycera Godm. (35 g) is confusingly like *Ceratinia antea*, but is somewhat smaller and the abdomen is grey-white beneath, in *antea* vivid yellow. It flies together with the similar forms on the upper Pastaza in Ecuador.

N. eunomia Godm., from Peru, corresponds to the similar *Ceratinia frater* from the same country. The black margins are narrower, the base of the hindwing is yellowish.

N. flossina Btlr. (35 g), from eastern Colombia and Ecuador, has transparent wings with narrow, dark margins and at the base of both wings yellowish colouring. — A very similar form is **hypsaeca** Stgr., from the Cauca Valley in Colombia. In it the veins at the end of the cell of the forewing are not margined with dark, and it is more weakly coloured at the base. The last two forms recall *Episcada paradoxa* and other similar Ithomias.

The following species, mostly smaller, have a dark oblique band across the end of the cell of the forewing. **N. ithra** Hew., from the Lower Amazon, and **potaronus** Kaye (35 f), from British Guiana, have a posteriorly forked, dark oblique band and whitish patch. In *ithra* the wings are slightly reddish, the margins narrow, dark brown, the base of the forewing and the distal margin of the hindwing yellow-red. *potaronus* has colourless wings with broader, dark margins and red-brown spots in the distal margin of the hindwing.

N. cyrianassa Dbl. & Hew. (35 g), from the Amazons and Colombia, may be recognised by the teeth of the black oblique band towards the apex. Hence the yellow oblique band is correspondingly sinuate. The hindwing has a broad, dark-edged, yellow-red submarginal band. — In **ercilla** Hew., from the Upper Amazon, the subapical band of the forewing is white and divided into spots. — **glycon** Godm., which is unknown to me in nature, is said to be similar to *cyrianassa*, but with a triangular, black spot in the cell of the forewing. — **adulta** Hsch. and **dilutata** Hsch. are local forms of *cyrianassa* from British Guiana. *adulta* is larger and more

brightly coloured. The base of the forewing is red-brown nearly to the end of the cell. In the apex is placed a row of red-brown dots. The red-brown band of the hindwing is broadly margined with black-brown. *dilutata* has narrower wings and yellow-brown ground-colour, which is extended beyond the end of the cell of the forewing and also borders the distal margin.

inachia. **N. inachia** Hew. (35 g) is very similar to *cyrianassa*, but the projection is absent at the end of the cell of the forewing, which is more transparent yellowish at the base. The antenna is dark. — In the local form *moles* **moles** Hsch., from British Guiana, all the margins and borders are broader. The disc of the hindwing is yellowish. The wings are short and broad. — *tunantina* **tunantina** Bates, from the Upper Amazon, is said to be similar to *cyrianassa*, but with oval subapical spot on the forewing, so that the black oblique band at the end of the cell is continued to the distal margin in the same width. — *adelphe* **adelphe** Bates, from the Lower Amazon, is likewise said to be very similar to *cyrianassa*, with less transparent wings. Apical spot of the forewing almost uniformly broad. The black oblique band gradually narrowed.

pheranthes. **N. pheranthes** Bates, from the Upper Amazon, is said to be similar to *inachia*, but with black collar and patagia, which are red-brown in the other forms.

pyrois. **N. pyrois** Bates, from the Lower Amazon, is likewise similar to *inachia*, but has no yellowish brown in the forewing. The anterior half of the hindwing, moreover, is yellowish.

corena. **N. corena** Hew. (36 b), from the Upper Amazon, as well as from eastern Peru and Ecuador, may be recognized by the broad, yellow-brown subapical band of the forewing, which is quite similar also in species of other genera, e. g.: *Dismorphia erythroë*, *Leucothyris ilerdina*, *lubilerda*, *Hypoleria sarepta* and others.

lamia. **N. lamia** Hew. resembles *Scada ethica* (36 d), but is appreciably larger and has larger white marginal dots, especially in the hindwing, as well as a non-forked band over the end of the cell on the latter.

galinthias. A similar form is **N. galinthias** Hpffr., from Bolivia, in which the dark marking over the end of the cell of the hindwing is absent.

rhezia. **N. rhezia** Hbn. recalls *Ceratinia laphria*, but the black spot in the cell of the forewing and the white marginal dots on the upper surface are absent. The species occurs in Brazil.

xanthone. In **N. xanthone** Bates (= *yanetta* Hew.) (36 b), from southern Brazil, the red-brown colouring on both wings is absent except for 2 streaks at the base of the forewing. — ab. **richardi** Fruhst., from Central Brazil, on the other hand has stronger red-brown markings at the base of the forewing and in the distal margin of the hindwing.

leptalina. **N. leptalina** Fldr., from Central Brazil, has similar markings to *xanthone*, but without red-brown at the base of the hindwing. It recalls *Dismorphia methymna*.

crispina. **N. crispina** Hew., from Colombia, has a reddish base to the forewing and a dark spot at the costal margin at one-half the length of the cell. The black distal margin is proximally dentate on the veins.

benigna. In **N. benigna** Weym., from Colombia, there is a reddish streak over the median of the forewing and the half-band on the discocellular is broad at the median.

sulphurina. **N. sulphurina** Bates (= *chinia* H.-Schäff., *pozziana* Oberth.) (36 a) is a yellowish, dark-margined species from the Amazons and Brazil, recognizable by the black streak over the median at the base of the forewing and 2 white dots in its apex, as well as by the black antennae.

osuna. **N. osuna** Hew., from Bolivia, has broad black margins and in addition to the transverse band across the end of the cell of the forewing an interrupted band across that of the hindwing, as well as a band through the cell of the forewing. — In *azeka* **azeka** Hew. (35 g) the markings are similar, but more delicate. The bands through the cell of the forewing and across the end of the cell of the hindwing are here only indicated by the absence of the yellow dusting (which is not brought out well in the figure); also the oblique band at the end of the cell of the hindwing is quite narrow from the middle onwards. Colombia and Ecuador. — *gracilis* **gracilis** Hsch., from Bolivia, is similar to the preceding, with narrower margins and broader half-band across the end of the cell of the forewing, and without the band through the middle of the cell and across the end of the cell of the hindwing.

pteronymiensis. **N. pteronymiensis** Hsch., from Colombia, has a colourless forewing and a yellow-dusted hindwing with dark margins spotted with yellow-brown beneath and a half-band of the same colour across the end of the cell of the forewing. Antenna dark with yellow-brown club. Apex of the forewing and distal margin of the hindwing with white marginal dots on the under surface.

elva. **N. elva** Godm., from Colombia, which is unknown to me in nature, is said to have transparent wings with the margins blackish above and reddish beneath.

pharo. **N. pharo** Fldr. (36 b), from the Upper Amazon, is a commoner species, with yellowish vitreous areas and broad black margins, which have yellow-brown stripes beneath. The transverse band of the forewing is gradually

pointed. The antennae are black. — In the similar *avila* Hsch., from eastern Ecuador, the club of the antenna *avila*. is yellow-brown, the wings are narrower and the forewing has beneath 7 white marginal spots, in *pharo* only 3—4 apical spots. — *crocodes* Bates, from the Upper Amazon, differs from the preceding by the black collar *crocodes*. and patagia, which in the latter are red-brown.

N. thira Hew., from Peru, has the size and markings like *syphis* Guér. (36 a), from Bolivia, but a red- *thira*. yellow stripe in the distal margin of the hindwing. On the under surface both forms have yellow-brown, dark- *syphis*. edged margins and 2 white dots in the apex.

The similar **N. verticilla** Hew. (36 a) has only a dark half-band across the discocellular and towards the *verticilla*. apex a smaller, white patch. — *sodalis* Hsch., which occurs together with the preceding at the boundaries of Peru *sodalis*. and Bolivia, is similarly marked. It has, however, a yellow base to the costal margin of the hindwing beneath, whilst in *verticilla* this is yellow-brown like the other margins.

18. Genus: **Sais** Hbn.

This small genus contains only a few forms of scarcely medium size, which are all very nearly allied and occur in northern South America, but are mostly not common. The species may be recognized by the long cell of the hindwing with feebly angled middle discocellular and by the strongly aborted forelegs of the ♂♂.

S. paraënsis Hsch. (36 c), from the Lower Amazon, has yellow-brown ground-colour; apex and 2 spots *paraënsis*. at the end of the cell of the forewing, as well as distal margin and median band on the hindwing, black-brown. Forewing with broad yellow oblique band. — *badia* Hsch. (= *mosellina* Stgr. i. l.), from the Upper Amazon, *badia*. is a large local form with chestnut-brown ground-colour and smaller yellow oblique band. — *camariensis* Hsch., *camariensis*. from British Guiana, has light yellow-brown ground-colour, a large red-brown spot in the apex of the forewing and a yellow longitudinal band at the median of the hindwing. — In *rosalia* Cr., the oldest form, from Surinam, *rosalia*. the apex is not black-brown but like the yellow-brown ground-colour. Otherwise this form is very near to *paraënsis*. — In the larger *virchovi* Dew. the apex of the forewing is black-brown and the yellow oblique band very narrow *virchovi*. and dentate. — *mosella* Hew. (36 c), which likewise comes from Venezuela, has a red-brown spot at the apex of the *mosella*. forewing, whilst the median band of the hindwing is almost entirely absent.

S. promissa Weym. and *zitella* Hew. (36 c) have broader wings and a yellow-brown apex to the forewing *promissa*. with black-brown marginal teeth, much as *Ceratinia pardalina*. The spots of the median band and the distal- *zitella*. marginal teeth of the hindwing are merged together in pairs into black stripes, so that streaks of the yellow-brown ground-colour are left between them. Both forms fly on the Upper Amazon, and *promissa* has a large, broad, yellow oblique band, like *paraënsis*, whilst in *zitella* this is short and narrow.

19. Genus: **Scada** Kirby.

This genus includes only a few delicate, yellow and black forms, which are almost all very similar and mostly occur in the neighbourhood of the equator. It has the forelegs of the ♂♂ strongly aborted in common with the preceding genus and the superficially similar *Aeria*. It may be recognized especially by the long upper discocellular, which to some extent forms a branch of the subcostal. — In size some forms are inferior even to the true Ithomiids and are hence the smallest of the whole family.

The *Scada*-species mostly occur in the thick undergrowth in the primeval forest, only coming into the open spaces in dull weather, when they are found feeding at small, white star-shaped flowers.

The rare **S. zemira** Hew. (36 d), from Ecuador, is the only species which in addition to very broad black *zemira*. markings has also a red-brown double spot at the hinder angle of the forewing.

S. kusa Hew. has somewhat narrower margins, it differs from the normal markings in that the oblique *kusa*. band joins the inner margin of the forewing, cutting off a yellow spot at the hinder angle. It flies, like the smaller *ethica* Hew. (36 d), in Ecuador. In the latter a yellow spot at the apex of the hindwing is cut off by a blackish *ethica*. transverse band across the end of the cell, as is also the case in *Napeogenes lamia* and *Ithomia derasa* from the same localities. — *excellens* Srka. is a local form from Ecuador, in which the black distal margins are almost *excellens*. entirely suppressed, the marginal dots being very large and yellow. — *quotidiana* Hsch., from the middle Napo *quotidiana*. in Ecuador, approximates to *ethica*; but the characteristic transverse band on the hindwing is absent.

S. zibia Hew. is a similar species from Colombia and Ecuador with more pointed apex to the forewing *zibia*. and red-brown collar. — *xanthina* Bates (36 d) is a similar form with broader, deeper black margins and more *xanthina*. vivid yellow. It is the only Central American form; from Panama and Costa Rica. — *amplificata* Hsch., from *amplificata*. eastern Colombia, is larger, with broad blackish margins and larger white marginal dots, especially at the apex of the forewing.

- philemon*. **S. philemon** Fldr., from Venezuela, is said to be very similar to *reckia* Hbn., but to have red-brown collar and patagia.
- theaphia*. **S. theaphia** Bates (36 d), from the Lower Amazon, is the smallest species of the genus and also of the whole family. Examples occur in which the wing-expanse is less than 30 mm. It has very delicate, yellowish wings and a straight, black oblique band at the end of the cell of the forewing. — **batesi** Hsch., a local form from the Upper Amazon to Ecuador, is larger, more vividly coloured, with broader black margins. — **majuscula** Hsch. is a larger form from British Guiana. It has broad deep black margins and very small white marginal dots. On the under surface there is a red-brown streak in the distal margin near the inner angle.
- reckia*. **S. reckia** Hbn., from northern Brazil, is a smaller species and may be recognised by the absence of the white marginal dots on the upper surface. The yellow ground-colour is only slightly transparent.
- ortygia*. In **S. ortygia** Druce (= *garleppi* Stgr. i. l.), from Peru, the white marginal dots are likewise absent; but it is considerably larger with very long, pointed wings. The dark margins, especially in the ♂, are very transparent; the inner margin of the forewing very broad.

20. Genus: **Dircenna** Dbl. & Hew.

With this begins the group of the true *Ithomias*, in which the lower discocellular of the hindwing forms a sharp angle with the median, so that the cell is short.

In *Dircenna* the palpi are strongly hairy, the cell of the hindwing is short. The forelegs of the ♀♀ are four-jointed. The genus comprises for the most part fine-looking species with transparent wings and short antennae. Representatives of this genus are found almost everywhere from Mexico to Argentina; they are mostly not rare and some, such as *klugi* from Central America and *dero* from Brazil, are among the commonest butterflies of the respective districts.

- klugi*. **D. klugi** Hbn. (36 e ♂, ♀). The ♂ has longer hindwing and more delicate colouring, which is not sufficiently brought out in the figure; the hindwing in the ♂ is yellowish, only at the inner angle yellow-brown, not red-brown, in the ♀ uniformly yellow-brown. Examples from the volcano Chiriqui in Costa Rica, which I therefore call **chiriquensis** *form. nov.*, are distinguished from typical specimens from Mexico, Honduras, etc., by brighter colouring and also by a much broader spot in the cell of the forewing. In the ♂ the distal margin of the hindwing is broadly coloured with red-brown near the dark border and proximally distinctly defined by the transparent basal part.
- relata*. **D. relata** Btlr. & Druce, from Costa Rica, has a blackish base to the forewing, blackish apex to the hindwing and a broad, vitreous oblique band on the hindwing, especially in the ♀. — **olyras** Fldr. (36 e) is a very similar, larger and much more brightly coloured form from Colombia, which recalls *Olyras montagui* and *Ceratinia excelsa* by the vitreous oblique band of the hindwing, especially on the underside (which is not visible in the figure) and other markings. In the ♀ the hyaline spots of the forewing and the oblique band of the hindwing are yellow. — **lonera** Btlr. & Druce is another, similar form from Costa Rica with blackish spot at the median of the forewing and blackish veins. The disc of the hindwing is colourless. The abdomen is beneath black-brown, not yellow as in *olyras*.
- jemina*. **D. jemina** Hbn. (36 e ♂, ♀) has a dark spot in the middle of the cell of the forewing and red-brown inner margin and median. The hindwing in the ♂ is blackish at the inner margin, in the ♀ with spots across the dark median veins. The species varies somewhat, the ground-colour ranging from pale red-brown to yellow; it occurs in Colombia and Venezuela, but is said also to be found in Nicaragua (= *jambe* Dbl. & Hew.). — **bairdi** Reak. is said to be similar to *jemina*, with black inner margin of the forewing. The basal half of the hindwing is ochreous, the distal half blackish with black veins. — **euchytma** Fldr. (36 f ♂, ♀) has shorter wings and red-brown inner margin. Across the cell runs a forked, black oblique band and through the cell a half-band. The hindwing has broad distal margin. The ground-colour of this wing is yellowish with red-brown veins. In Colombia and Venezuela; common.
- visina*. **D. visina** Hsch. (36 f), from eastern Ecuador, has almost colourless wings with very slight whitish smears, as in *olyras*. The median of the forewing is broadly red-brown.
- sunu*. **D. sunu** Hsch., from western Ecuador, is a very similar, smaller species, in which only the club of the antenna is yellow-brown. The spot in the cell of the forewing is linear, as in *marica*. In the ♀ the subcostal of the forewing is also red-brown, as well as the veins in the disc of the hindwing.
- marica*. **D. marica** Fldr. (36 f ♂, ♀), from Venezuela, and **steinheili** Stgr., from Colombia, are two nearly allied forms with black antennae. In *marica* the patches at the end of the cell and the apex are yellowish, in *steinheili* whitish.

D. mantura Hew. (36 g) may be recognized by the broad band across the end of the cell of the forewing *mantura*. to the distal margin. In this it recalls some *Thyridia* and *Aprotopos*. Bolivia.

D. loreta Hsch. (36 g), from Ecuador, is a similar, larger species, without the band in the hindwing. *loreta*.

D. xanthophane Hpffr., from Peru, has narrower, dark margins and vivid sulphur-yellow veins in the *xantho-* disc of the hindwing, as well as a yellow base on the underside of the wing. *phane*.

D. dero Hbn. (= *celtina* Burm.) (36 g ♂, ♀) is somewhat smaller, with short, yellowish club to the *dero*. antenna. The band across the middle of the cell of the forewing is somewhat curved. In the ♀ the margins and bands are broader. Southern Brazil to Paraguay and Argentina; very common. — **rhoeo** Fldr. is an allied form *rhoeo*. from northern Brazil, with ochre-yellow colour, also on the veins, particularly in the hindwing.

D. hugia Schaus, from Bolivia, is said to have yellow-grey wings with brown veins and margins, which *hugia*. are broadest at the end of the veins; with yellow spots at the end of the cell and the distal margin.

D. honrathi Srka. (36 g) is a rare species from Chanchamayo in Peru, with delicate, blackish margins, *honrathi*. without spot through the cell of the forewing; with larger, whitish dots at the apex of the hindwing.

D. vandona Hsch. (37 a) recalls the similar species of *Ceratinia*, *Napeogenes*, etc., by the red-brown *vandona*. patch at the inner angle of the hindwing. The wings are otherwise colourless except for the yellowish base of the hindwing; the dark distal margins sharply defined. It flies together with ab. **immaculata** Hsch., in which *immaculata*. the red-brown patch at the inner angle is absent, in the eastern Andes of Ecuador at the upper Pastaza River.

D. lorica Weym., from Guiana, is a smaller, colourless species with narrow, brown margins, without *lorica*. band across the end of the cell of the forewing.

The beautiful **D. varina** Hew. (37 a), from the eastern Andes in Ecuador, is a very distinct, brightly *varina*. coloured and rare species. The base of the forewing and the hindwing are delicate red-brown; the apex of the forewing black; across the end of the cell a broad yellow macular band with 3 dark spots: all semitransparent. — In ab. **partita** Hsch. the yellow oblique band is broken up into separate spots by a black band across the end of *partita*. the cell.

D. pulcheria Hew., from Ecuador, has the hindwing and the base of the forewing orange-coloured. *pulcheria*. The greater part of the forewing is blackish with yellow spots in and below the cell.

D. euteles Ersch., from Cayenne, is not known to me. *euteles*.

D. lenea Cr. (♀ = *melanida* Cr.) (37 a ♂, ♀), from the north-east of South America, has in the hindwing *lenea*. a peculiar, blackish longitudinal band, which is interrupted at the apex. Between this and the dark distal margin the colour is red-brown, proximally yellow in the ♂, reddish in the ♀. The forewing has a yellow oblique band; the base is red-brown, apex and end of the cell are black. — **elvira** Weym. is a very similar form, in which the *elvira*. black and the red-brown band completely surround the apex.

D. methonella Weym. (37 a) has yellowish wings with black margins and half-band across the end of *methonella*. the cell of the forewing. Behind the end of the cell of the forewing and in the disc of the hindwing the veins are partly yellow-brown. In the ♀ the margins are much broader and in the cell of the forewing there is a triangular spot at the median. It flies in southern Brazil and Paraguay. — **xantho** Fldr., from Central Brazil, is a similar *xantho*. form with yellow-brown spot in the cell of the forewing, yellow-brown veins in the hindwing and stronger yellow dusting. Larva according to W. MÜLLER on *Solanum*; the body is cylindrical, without appendages, greenish, the head very large. The pupa is short, at the ventral side strongly convex, transparent green, the greater part with a golden gloss. — **D. hulda** Fldr., from Venezuela, is said to be similar to *xantho*, but larger, with narrower *hulda*. subapical spots in the forewing and without yellow-brown in the cell.

In **D. obfuscata** Btlr., from the Upper Amazon, the base of the forewing is black. The spots at the distal *obfuscata*. margin yellowish. Hindwing near the base of the inner margin with large, transparent brownish spot and 2 smaller ones at the apex.

D. zelia Guér., from Bolivia, is said to be allied to *dero*, with black margins and band across the end *zelie*. of the cell. Veins at the base of the hindwing yellow.

D. epidero Bates, from the Amazons, has on the hindwing from the costal to the distal margin a black *epidero*. transverse band, like *Thyridia confusa*; in the cell of the forewing a triangular, black spot is placed at the median. — In ab. **signata** ab. nov. Stgr. i. l. (37 b) there are red-brown spots in the black distal margin of the hindwing, *signata*. sometimes also at the base of the forewing.

21. Genus: **Epithomia** Godm. & Salv.

This genus only contains a few forms, which were formerly placed in *Dircenna*. The species are distinguishable especially by the short hairy palpi, the 5-jointed tarsi of the ♀♀, and also by the presence of the upper discocel-

lular in the hindwing. Superficially they resembles some species of *Callithomia*, *Ithomia* and *Calloleria*. Their area of distribution is confined to north-west South America and Panama.

agrippina. **E. agrippina** Hew. (= *callipero* Bates, ♀ *balboa* Bates) is the same size as the figured *alpo*. Base of the forewing and the hindwing red-brown, the latter with broad, dark margin. Forewing with 2 yellow oblique bands across the end of the cell and at the apex, as well as a spot between these at the distal margin. The rest of the apical half is blackish, also a spot in the cell. The species flies in Colombia and Panama. — In a form *fumantis*. from Colombia, which I call **fumantis** *form. nov.*, the dark margin of the hindwing is proximally spot-like, irregular, widened almost to the cell. The ground-colour is darker. The white marginal spots of the under surface are very large.

alpo. **E. alpo** Fldr. (37 b) has semitransparent wings with diffuse, yellow-brown colouring and similar markings to *agrippina*. — In a form which like *alpo* comes from Venezuela, there is a median band in the hindwing which *nikita*. is composed of 3 angular, dark spots. I call this form **nikita** *form. nov.*

22. Genus: **Ithomia** Hbn.

Formerly most of the small, transparent forms of the family were included under this name. At the present time we understand by it a smaller, but still numerous group whose best distinguishing characters are the large, oval scent-spot of the ♂♂ and the long cell of the hindwing with angled lower discocellular. Very striking in many ♂♂, e. g. *hyala* (37 c), are the large broad forewing and small hindwing; in the latter the costal margin is strongly arched anteriorly by the scent-spot. In the ♀ the cell of the hindwing is cut off rather straight, a vein extending into the cell. The variety of colour and form in this genus is very great; it contains both gay-coloured species which closely resemble certain *Ceratinia* and *Napeogenes* and also inconspicuous, colourless forms, which are mimicked by species in the following genera. The area of distribution of the genus is correspondingly also a very large one, including the whole of the Neotropical Region. North-Western South America, however, produces the most representatives of this, as also of other genera.

heraldica. **I. heraldica** Bates (37 b), from Costa Rica, has black-brown forewing with red-brown base, 3 yellowish *plaginota*. macular oblique bands and whitish subapical dots. The hindwing is red-brown with dark distal margin. — **plaginota** Btlr. & Druce (37 b) is a similar, larger and more brightly coloured form from the same district. In it the yellow subapical and marginal dots are more strongly developed; but of the oblique bands only the distal one and the half of the median band in the cell are yellow. The base of the forewing is more broadly red-brown.

celestia. In **I. celestia** Hew. (37 c), from Colombia, the oblique bands are broken up into smaller spots. The *lurida*. distal margin of the hindwing is broader and in it are placed yellow dots. — **lurida** Hsch. is a local form of the preceding from the Cauca Valley in Colombia with very large, band-like spots in the disc of the forewing and large dots in the apex of the forewing and the distal margin of the hindwing. — **candescens** Hsch. is a form of *splendens*. *celestia* from Colombia and Venezuela with white instead of yellow spots and dots. — **splendens** Hsch. is coloured like *candescens*, but with very large, white spots and dots, corresponding to *lurida*.

iphianassa. **I. iphianassa** Dbl. & Hew. is a somewhat smaller, very variable species, of which *anaphissa* (37 c), *panamensis* (37 c) and others are merely local forms. *iphianassa*, from Venezuela, best represents the *Lycorea*-habitus and the pattern of the other forms can be derived from it. The scheme of markings is the same as in *anaphissa*, but the base of the forewing and the hindwing yellow-brown. The latter with undulate distal margin and black-brown longitudinal band, bent in hook-shape at the apex. The basal area, especially in the ♂, is lighter yellowish, semitransparent, with dark dots at the end of the cell. The forewing has an indistinct, yellow-brown median band and a yellow subapical band; between them is placed at the distal margin a roundish, yellowish spot. The rest of the apex and 2 spots in the basal part are black-brown; apex with 2 or more whitish marginal dots. In **anaphissa** H.-Schäff. (= *pepita* Oberth.) (37 c), from Colombia, the distal margin of the hindwing and the median band are united into a broad, black distal margin; also the apical half of the forewing is more *panamensis*. broadly black with larger, white marginal dots. — **panamensis** Bates (37 c), from Panama, has a much broader, dark distal margin to the hindwing, which reaches to the end of the cell. The yellow subapical band of the forewing *lycaste*. is entirely suppressed except for 4 very small spots. This form strongly recalls *Mechanitis macrinus*. — **lycaste** F. *negrita*. is a very similar form from Kansas in North America with still more strongly black markings. — **negrita** Reak., from California, is another allied form, in which the black median spot of the forewing is enlarged, half of it *boucardi*. being on the hindwing. — In **boucardi** Druce, from Panama, the yellow median band of the forewing is absent. The whole basal half is yellow-brown with large, black median spot. The broad distal margin of the hindwing *pumensis*. and a spot at the end of the cell are black. — As **pumensis** REAKERT designates a form of *iphianassa*, from Venezuela, with larger black spots and red-brown basal part, without the yellow median band. The yellowish spot at the distal margin is very small. The forewing has 3 white dots at the distal margin.

I. phanessa H.-Schäff. and **alienassa** Hsch. (37 d), from Colombia, have transparent yellowish wings. *phanessa* has broad, yellow-brown submarginal distal border to the hindwing and in the cell of the forewing an isolated, triangular spot. In *alienassa* the distal margin of the hindwing is black-brown with red-brown macular streak, and across the middle of the cell of the forewing there is a dark half-band. *phanessa*. *alienassa*.

I. cleora Hew. (= *chimborazana* Reak., *spruceana* Bates) (37 c ♂, ♀), from western Ecuador, was formerly often confused with the preceding two. It may, however, be recognised at once by the long, pointed, black spot in the cell of the hindwing. On the other hand the red-brown colouring varies very much. There are ♂♂ in which this is almost entirely absent and ♀♀ in which the basal half of the forewing and of the hindwing are almost entirely red-brown.

I. epona Hew. (37 d) has transparent smoke-brown wings with darker margins; half-band across the end of the cell of the forewing, as well as median spot in the cell. In the ♀ the distal margin of the hindwing is broader, with whitish dots. The species flies in the mountains of eastern Ecuador at elevations of 1500—3000 metres together with the similar *Dismenitis hewitsoni*. *epona*.

I. xenos Bates (37 d) is a similar species with narrower wings, from Costa Rica. The forewing has slightly yellowish patch and a dark half-band through the middle of the cell. The distal border of the hindwing in the ♂ is very narrow. In the rare ♀ the margins and patches are broader, at the median of the forewing and on the hindwing proximally red-brown. *xenos*.

I. ulla Hew. (= *radata* Weym.) (37 e) is another species from Colombia, but with peculiar neuration. *ulla*. BOISDUVAL erected for it the genus *Tagyris*. The forewing is very broad; the discocellulars close the cell in arc-shape and form an acute angle with the very small third section of the median vein. The scent-spot of the hindwing terminates with a neck at the end of the cell, as in *Hypoleria*-species. *ulla* has behind the band at the end of the cell of the forewing a yellowish patch and a yellow-brown subcostal. In the ♀ the margins are broader and there is also a half-band across the end of the cell of the hindwing. — The same neuration is found in **dimidiata** Stgr., *dimidiata*, from the Cauca Valley and eastern Ecuador. This species has slightly smoke-brown wings with brown margins, but without half-band across the end of the cell and without yellow patch.

Another similar species is **I. mira** Stgr., from the Amazons, but with different neuration, red-brown subcostal and small spot at the end of the cell of the forewing. *mira*.

I. peruana Salv. (= *abendrothi* Hpfr.) (37 d) has transparent, yellowish wings with broad, black margins and half-bands across the end of the cell and through the cell of the forewing. It occurs at Chanchamayo in eastern Peru. *peruana*.

I. linda Hew. (37 d), from Ecuador, has exactly the appearance of *Ceratinia antea* and *Napeogenes glycera*, with which it also flies in company. It is somewhat smaller and the ♂ is conspicuous by the broad costal margin of the hindwing. — **theuda** Hew., likewise from Ecuador, is a very similar species with somewhat yellowish wings and black antenna, whilst in true *linda* the club of the antenna is yellowish. *linda*. *theuda*.

I. nigrimargo Btlr., from Ecuador, approximates to the preceding, but has a red-brown spot at the anal angle of the hindwing and is hence very similar to *Ceratinia adelinda* and other forms. *nigrimargo*.

I. lagusa Hew., from Colombia, and **I. hymettia** Stgr. (37 d), from the Cauca Valley, strongly recall certain *Napeogenes*-species. The neuration of the ♂♂ almost exactly agrees with that of this genus in the long cell of the hindwing with the lower discocellular only weakly curved proximad. The forms may, however, be recognized with certainty by the scent-spot of the ♂♂ and the recurrent cell-vein in the ♀. In *lagusa* ♂ the basal third of the forewing is black-brown with oblong yellow-brown spot and broad half-band at the end of the cell. In the ♀ the dark margins at the base are narrower, at the apex and at the distal margin of the hindwing on the contrary broader. *hymettia* has colourless wings, broad inner margin to the forewing and yellow-brown streak at the median; further a half-band at the end of the cell and in the ♂ narrow, in the ♀ broad, dark margins to both wings. *lagusa*. *hymettia*.

The beautiful **I. ellara** Hew. (37 e), from Bolivia, has colourless wings with broad black margins and patches at the end of the cell and in the cell of the forewing, and large, transparent marginal spots. On the under surface the markings are for the most part brown-red. The antenna has a yellow-brown club. — The very similar **eleonora** Hsch., from the border of Peru and Bolivia, has narrower distal margins, without the transparent marginal spots, but at the costal margin of the forewing a suggestion of a subapical band, and also black antenna. — In an aberration, which I call ab. **beata** ab. nov., there is a large, yellow-brown spot in the distal margin at the inner angle of the hindwing above. — **avella** Hew. (♀ = *cesleria* Hew.) (37 e), from Colombia, is a similar, smaller species with red-brown subcostal to the forewing and without the dark colouring in the cell of the hindwing. The ♂ has considerably narrower margins and patches than the figured ♀. *ellara*. *eleonora*. *beata*. *avella*.

The ♂ of **I. hyala** Hew. (37 e) is conspicuous by the broad forewing and small hindwing. The wings are slightly smoke-brown with dark margins and 2 half-bands through the cell and at its end. The base of the hindwing is yellow beneath. In the ♀ the wings have the usual shape, somewhat as in *diasia*. *hyala*.

- diasia*. **I. diasia** Hew. (37 f) is a similarly marked species, without the striking forewing of the ♂♂, with glossy bluish wings margined with black. On the under surface the margins in this species are also black in exceptional cases except for the costal margin of the hindwing, which is brown and at the base yellow.
- ossuna*. As **I. ossuna** spec. nov. I designate an interesting species from Colombia, which is similar in pattern and colouring to the preceding species except for the distal margin of the forewing. This is much widened before the inner angle and red-brown.
- hippocrenis*. **I. hippocrenis** Bates, from southern Central America, is similar to *diasia*, but has a much broader spot at the end of the cell of the forewing and also a white patch, as well as red-brown margins on the under surface. —
- morena*. **morena** Hsch. is another similar form from western Ecuador. The wings are colourless; the markings as in *diasia*, only the half-band in the cell is reduced, and the margins are beneath red-brown with dark edges.
- aelia*. **I. aelia** Hew. (= *centromaculata* Weym.) (37 g) has whitish-dusted forewing with dark margins and veins, as well as broad band across the end of the cell of the forewing. The hindwing is light red-brown with dark costal and distal margins. This rare species flies in Eastern Colombia.
- jucunda*. **I. jucunda** Godm. & Salv., from Panama, has similar forewing, but colourless hindwing with broad, black-brown distal margin and a red-brown spot in it near the inner angle. The species thus recalls *ossuna* and
- galata*. is distinguished by the absence of the half-band in the cell of the forewing. — **galata** Hew., from Colombia, is also similar, with narrower band at the end of the cell of the forewing, and moreover yellow-brown, dark-edged distal margin to the hindwing.
- patilla*. **I. patilla** Hew. (= *psyche* Bates) (37 f), from Central America, has a black-brown apical half to the forewing with a large white subapical patch; the base and the hindwing are colourless, with dark red-brown
- leila*. margins. — **leila** Hew., from Mexico, is larger, with broader bands and spots, and white dots in the apex of the forewing and at the distal margin of the hindwing.
- terra*. **I. terra** Hew. (37 f), as well as **terrana** Hsch. and a third form, which I call **vulgana** form. nov., may be
- terrana*. recognized by the broadly dark-margined veins at the end of the cell of the hindwing. *terra* is one of the most
- vulgana*. widely distributed and commonest Ithomias; it occurs in north-western South America, from Colombia and Venezuela to Bolivia. The wings are transparent, shiny bluish, with triangular, black spot at the end of the cell of the forewing and small white spots near it at the costal margin. The black margins of the upper surface are beneath red-brown with dark edges. Whilst *terra* occurs in the eastern part of the Andes in Ecuador, the smaller *terrana* is found in the west. The wings in this form are colourless, with broader margins and large, white patch at the apex of the forewing. On the under surface the colour of the margins is yellow-brown. *vulgana*, from Costa Rica, has the colouring as *terrana*, with narrower, black-grey margins and smaller white patch. In size it is intermediate between *terra* and *terrana*. On the under surface the margins are yellow-brown with fine, dark border. The scent-spot of the ♂ in *vulgana* is yellow-brown, in the other two forms black-brown.
- derasa*. **I. derasa** Hew. (= *mellilla* Weym., *soligena* Weym.) (37 f) has dark-shaded veins at the end of the cell of the hindwing, like the very similar *Napeogenes lamia* and *Scada ethica*, which species likewise have yellow-dusted wings. *derasa* was described by HEWITSON from Nicaragua. But I find no difference between it and the
- travella*. form described from eastern Ecuador by WEYMER as *soligena*. — From thence also comes **travella** Hsch., which is similar to the preceding; but the dark marking at the end of the cell of the hindwing is absent and the band
- salapia*. at the end of the cell of the forewing is broader. — **salapia** Hew. (37 f) has the wings more weakly dusted with yellow and broader, black margins, without white dots in the anal margin and with red-brown central line in the margins of the underside.
- drymo*. **I. drymo** Hbn. (= *diaphana* Cr., *phono* Geyer) (37 g ♂, ♀) is a small, inconspicuous species, common in Brazil, with colourless, dark-margined wings and broad half-band across the end of the cell of the forewing. At the costal margin follows a small, white spot. In the ♀ the margins are somewhat broader and across the
- napho*. end of the cell of the hindwing is placed a triangular, dark spot. — **napho** H.-Schäff. (= *phono* Hew. p., *naxo* Oberth.), from Colombia, is a very similar form with slightly smoke-brown wings and without the spot at the
- pellucida*. discocellular of the hindwing in both sexes. — **pellucida** Weym. is also a very similar species with longer oblique band at the end of the cell of the forewing. It is said to occur both on Trinidad and in Brazil.
- agnosia*. **I. agnosia** Hew. (37 f), from Colombia and Venezuela to Peru, is a common species with similar markings to the preceding, but distinguishable by the large, white patch at the end of the cell of the forewing.
- pseudo-agalla*. **I. pseudo-agalla** Reb. (37 g), from western Ecuador, has smoke-brown wings with dark margins; yellow spot at the end of the cell and yellow-brown median vein on the forewing.
- oenanthe*. **I. oenanthe** Weym. (37 g) has more pointed forewing with brownish margins, which are vivid yellow-brown on the under surface. The half-band at the end of the cell of the forewing is pointed. It flies in the Cauca Valley of Colombia and is closely allied to *terra*.
- salcata*. **I. salcata** Schaus, from Colombia, is said to have transparent, whitish wings, with black-brown veins and margins. Forewing sparsely scaled with white at the end of the cell and the costal margin. On the under

surface the margins are light reddish brown with dark edges; forewing with 3 white apical spots. Hindwing yellowish at the costal margin, at the distal margin with small, white dots.

Whilst in the forms already dealt with the dark oblique band of the forewing was more or less distinctly forked, in the following otherwise similar species it is simple, tapering to a point posteriorly.

I. amarilla Hsch. (37 g) has very similar markings and colouring to *travella*, but the oblique band is *amarilla*, gradually pointed posteriorly. It flies with the latter on the upper Napo.

I. aquinia Hpffr., from Peru, is very similar to *salapia*, but with a simple oblique band. The 3rd median *aquinia* vein is not darkly coloured.

I. ardea Hew. (38 a) is very similar to *agnosia*, with the oblique band on the forewing prolonged to the *ardea* distal margin. It varies much in size and flies in Bolivia.

I. drogheda and **hamlini** Weeks, from Venezuela, are not known to me.

drogheda.
hamlini.

23. Genus: **Calloleria** Godm. & Salv.

Here belong a number of smaller forms which are almost all nearly allied and have mostly a red-brown ground-colour, with yellow oblique band on the forewing. The neurulation of the ♂♂ shows in the hindwing between costal and subcostal on the under surface a raised ridge, as well as an indistinctly angled lower discocellular with very long lower and very short upper divisions, so that it appears almost without angle; moreover with recurrent cell-veins as continuation of the lower radial. In the ♀ the neurulation is very similar except for the raised ridge.

The area of distribution extends over northern South America and the Isthmus of Panama to Costa Rica.

C. dorilla Bates (38 a), from Panama and Costa Rica, has between the red-brown base and the black- *dorilla*. brown apex an irregular, yellow oblique band which is connected with a yellow spot placed at the inner margin. The triangular, dark spot in the middle of the cell is mostly only indistinct; on the other hand the two at the end of the cell are very large and connected. In the apex are placed a larger and a smaller yellow spot, as well as several yellow dots at the distal margin. The hindwing is red-brown with dark distal margin and spot at the end of the cell. — The very similar **azara** Hew. (38 a), from eastern Ecuador and Colombia, has lighter, narrower *azara*. wings. The two spots at the end of the cell are smaller than in *dorilla*, so that the yellow oblique band is broader at the costal margin. Only one of the yellow dots at the distal margin is present here. The distal border of the hindwing is broader. — **tutia** Hew. (38 a) has even more transparent wings with narrower yellow oblique band *tutia*. and smaller apical spots; between the two appears another large, transparent, yellowish subapical spot. The hindwing has narrow distal margin and a distinct longitudinal band. This form flies in Venezuela and Costa Rica. — **tosca** Schaus, from Colombia, is a local form with yellow apex to the forewing and yellow colour between *tosca*. the median band of the hindwing and the distal margin. — **chanchamaya** Hsch. has similar markings to *tutia*, *chanchamaya*. without the yellow spots in the apex of the forewing, with stronger, black macular band in the disc of the hindwing and yellowish colouring between the disc and the costal margin. It flies at Chanchamayo in Peru.

In true **C. hopfferi** Weym. the yellow oblique band in the forewing is absent, the specimen figured represents *hopfferi*. a local form, which I call **onoma** form. nov. (38 a). Both forms fly on the Upper Amazon; they may be recognised *onoma*. by the red-brown colour of the large subapical spot of the forewing and resemble *Ceratinia pardalis* resp. *tigrina*. The marking is otherwise similar to that of *chanchamaya*. The distal margin of the hindwing, especially in *hopfferi*, is broken up into several spots.

C. poecila Bates (38 a) is a commoner, widely distributed species from Colombia, Ecuador and the *poecila*. Upper Amazon. It has a broad, distally dentate yellow oblique band and at the end of the cell 2 separated, roundish black spots. — **callichroma** is the name given by STAUDINGER to a form of *poecila* from Ecuador with narrow, yellow *callichroma*. band. — In **poecilana** Hsch., from eastern Ecuador, the median band of the hindwing is united with the distal *poecilana*. margin into a large, blackish spot. — In **azarina** Weym., also from Ecuador, there is a large black spot in the *azarina*. disc of the hindwing, which reaches to the base. — **nigronascens** Hsch., from the Upper Amazon, has the hindwing *nigronas-* black except the apex, which remains red-brown. *cens.*

C. selenides Weym. (38 a), from the Upper Amazon, has a yellow oblique band, widened in the middle *selenides*. towards the apex, which is also proximally bordered with black. The broad median band of the hindwing is continuous.

C. porrecta Hsch., from Bolivia, has longer, narrower wings, narrow yellow oblique band, similar to *porrecta*. *tutia*, and large blackish spots at the end of the cell. The hindwing has 3—4 sagittate spots in the disc. In the blackish apex of the forewing is placed a lighter, sometimes yellow-brown patch.

C. robusta Hsch., from Bolivia, is the same size as *dorilla*. The narrow, yellow oblique band is broken *robusta*. up into 2 spots. The hindwing is narrow, with dark margin. — In **fuscens** Hsch., the oblique band is also broken *fuscens*. up into spots, but its colour is the same as the ground-colour: transparent, faintly red-brown. The hindwing has 3 sagittate spots in the disc and narrow, proximally dentate distal border.

- singularis*. **C. singularis** *Reb.* is a form from western Ecuador with narrow, delicate wings. The yellow oblique band is narrow, not dentate towards the apex, provided with a projection towards the base. The median band of the forewing is broad, shadowy. The antenna is dark with brownish club.
- melanoptera*. **C. melanoptera** *Hew.*, from Ecuador, is a peculiar form with blackish wings, the cells of which are transparent yellowish brown, as also 3 larger spots at the distal margin of the forewing. On the under surface there are some quadrate reddish spots at the distal margin of the hindwing. It appears to be a melanistic aberration.
- nise*. **C. nise** *Cr.* (♀ = *selene Cr.*) (38 b ♂, ♀) has a yellowish, broad oblique band in the forewing, reaching to the inner angle, where it is strongly denticulate. The ground-colour in the ♂ is faintly red-brown, in the ♀ dark red-brown. The hindwing has a narrow median band, which is connected with the costal margin in bow-shape and in the ♂ forms the border of a transparent, light longitudinal band. *nise* flies on the Lower Amazon, as well as in Guiana and Venezuela. — **C. peruensis** *Hsch.* (38 b) is a similar form from the Upper Amazon, from Peru. The ground-colour is light red-brown in both sexes, with transparent longitudinal band at the base of the hindwing. The yellow oblique band of the forewing is still broader, not transparent, with small dark spots at the end of the cell. The dark spot in the cell is very faint. — **C. espriella** *Hew.*, from Ecuador, is a more strongly coloured form with dark apex to the forewing, without the transparent longitudinal band in the hindwing. — As **C. tarapotis** *form. nov.* I designate a form from the Lower Amazon, in which the yellow oblique band is almost entirely absent except for an indistinct spot at the costal margin. The colour, as in *espriella*, is vivid red-brown to the apex.
- radiosa*. In **C. radiosa** *Hsch.*, from eastern Ecuador, the apical half of the forewing is blackish, with radiate, yellow macular band. The dark spot at the base is elongate-pointed. The hindwing has a macular median band and dentate, dark distal margin.
- cayana*. **C. cayana** *Salv.* (38 b), from Guiana, has in the blackish apex a peculiarly formed, yellow oblique band with approximated spot at the inner angle. The spot in the cell is absent. The hindwing has a broad median band and both wings whitish marginal dots.
- jolaia*. **C. jolaia** *Hew.* (38 b), from Colombia, resembles *Napeogenes stella*. In the disc of the forewing there are a number of yellow spots, and in the distal margin of both wings large, yellow marginal dots; in the cell of the forewing a black, rounded spot and at the apex of the hindwing the commencement of a median band. — *conveniensi*. In **C. conveniens** *Hsch.* the spots in the forewing are united into an angular band at the end of the cell.
- doto*. **C. doto** *Hbn.* (38 b), from the Lower Amazon, is a very aberrant species with diaphanous wings; the margins and the discocellular of the forewing are margined with dark. The median of the forewing and a broad submarginal band on the hindwing are yellow-brown.

24. Genus: **Hyposcada** *Godm. & Salv.*

It is not possible to differentiate this genus very sharply from *Leucothyris*, as there is a gradual transition in the characters. Thus a number of forms which approximate to one another, as *ilerdina* and *ina*, have been placed in two different genera. I therefore only leave in this genus the forms which are allied to the typical species and place the others with the similar forms of *Leucothyris*.

Hyposcada is distinguishable by the long, thin antennae and the short cell of the hindwing. Costal and subcostal run at a distance from one another. Upper and middle discocellulars of the hindwing are short and almost equal in length. They are medium-sized butterflies of mostly red-brown ground-colour, which recall many species of *Ceratinia*. They occur especially in north-west South America, some also in Central America and are for the most part not common.

- adelphina*. **H. adelphina** *Bates* (38 c), from Colombia and Panama, has a broad, red-brown base to the forewing and red-brown hindwing with broad black distal margin. The rest of the forewing is black with a large number of white spots. Also at the apex of the hindwing are placed 2—3 white dots. The under surface is similarly marked to the upper. — **H. virginiana** *Hew.*, from Mexico and northern Central America, has narrower wings. The red-brown colour of the forewing reaches nearly to the end of the cell and the two white spots there are small and roundish. Especially worthy of note is the under surface, which is brown also in the whole apex of the forewing. — In a third form, from Costa Rica, which I call **C. evanides** *form. nov.*, the ground-colour of the forewing is black-brown except for two red-brown streaks at the base, and the same beneath. The wings are narrow as in *virginiana*, the white spots as in *adelphina*.
- consobrina*. **H. consobrina** *Godm. & Salv.* (38 c) is similar to the preceding, with larger, yellowish spots, without the two spots in the end of the cell of the forewing. It flies in eastern Ecuador, at the foot of the Andes.
- anchiala*. **H. anchiala** *Hew.*, from the Upper Amazon to Peru and Ecuador, has smaller white spots in the black apical half and a black streak at the median of the forewing, as well as black margins to the hindwing and a broad, spot-like median band in the disc.

H. abida Hew., from Colombia, is similar, somewhat smaller, without black streak over the median of *abida*, the forewing, with narrower median band on the hindwing. Both wings have small white marginal dots.

H. kezia Hew., from the Upper Amazon, has the markings like *anchiala*. But in the apex of the forewing *kezia*, there are only three white spots, the others are replaced by an irregular, yellow-brown band at the end of the cell. — In **rezia** Hsch. (38 c) the whole apex of the forewing is also yellow-brown except for the three indistinct whitish *rezia* spots, to each of which a black oblong spot is joined. This form flies on the Ucayali.

H. fallax Stgr. (38 c) is an interesting species from Chanchamayo in Peru, which strongly resembles *fallax*. *Ceratinia bicolora* and *semifulva*, as well as the larger *Mechanitis deceptus* and *Melinaca mothone*, by the black wings with broad red-brown bands. But it may be recognised, apart from the neurulation, by the long, thin black antenna and the differently placed black spots situated at the end of the cell and in the cell of the forewing.

H. aesion Godm. & Salv., from Panama, is similar to *abida*, smaller, without the white marginal dots *aesion*, and without the median band on the hindwing.

H. illinissa Hew., from the Upper Amazon, is similar to the preceding, with larger white spots and an *illinissa*, additional one in the cell of the forewing. The red-brown hindwing has in addition to the dark border a black submarginal band, curved correspondingly to the distal margin.

In **H. similia** H.-Schäff. (38 d) the whole base of both wings is black brown like the hindwing; on the *similia*, hindwing remains only a yellow-brown submarginal band at the distal margin.

25. Genus: **Leucothyris** Bdv.

This genus is as at present constituted rather extensive and might better be divided into several subgenera. Externally two principal groups are already differentiated: the first has shorter, rounded wings with broad whitish bands, often also with red-brown colour, especially at the apex of the forewing. The second has more pointed apex and peculiar whitish macular marking, especially at the apex and at the distal margin of the forewing, without brownish colouring. In the neurulation, however, both forms fluctuate between the typical short *Hyposcada*-cell of the hindwing and long thin antenna and long cell and shorter antenna with distinct club. In typical *Leucothyris* the costal and subcostal are said to run close together. The cell of the hindwing in the ♂ is longer anteriorly than posteriorly; the middle discocellular longer than the upper.

Considering the large number of forms which belong here it is not surprising that representatives of the genus are found in the whole Neotropical region; but as in most Ithomiids, the eastern slopes of the Andes from Colombia to Bolivia produce the greatest abundance of forms. The range of distribution of the separate forms is mostly very restricted. Almost every large river-valley has its distinct local form, which sometimes occurs there in great abundance, but a few hundred metres higher or lower, or about 10 miles to either side, is no longer met with.

On this account some forms of this and other genera remain for decades great rarities, until the restricted locality is at last revisited by some collector, who then obtains the coveted species in abundance.

L. ida Hsch. (38 d), from the Upper Napo in Ecuador, has black wings with milky vitreous spots and *ida*, a red-brown submarginal band on both wings. The latter is very broad in the apex of the forewing, as is also the case in a large number of similar forms. *ida* is distinguishable especially by the two white dots in the apex of the forewing, moreover the forewing has four white spots and a triangle at the base. The hindwing has a large whitish discal longitudinal band. In the ♂ the spots and band are smaller. — **idina** Hsch. is a smaller local *idina*, form from the Upper Amazon with indistinct dots in the apex of the forewing and broader, light red-brown apical band. Moreover, on the hindwing the red-brown submarginal band is lighter and broader. — **kena** Hew., from *kena*, eastern Ecuador, is considerably smaller than *ida*. The two vitreous spots at the apex of the forewing are confluent and completely enclosed by the red-brown subapical band. At the end of the cell three vitreous spots form an oblique band and the other three spots are also larger. — In **ilerdinoides** Stgr. (38 d) the two vitreous spots *ilerdinoides*, at the apex are absent, on the other hand there are two at the end of the cell. The red-brown subapical band of the forewing is broader. — Another similar form, which I call **lerda** form. nov., differs from the preceding in *lerda*, having only one spot at the end of the cell of the forewing, on the other hand there is another at the lower angle of the cell in the disc. These forms fly on the Upper Amazon, but each of them probably occurs in a separate district.

Whilst the preceding forms have a short cell, like *Hyposcada*, in the following, otherwise very similar forms, the middle discocellular of the forewing, and hence also the cell, begins to be appreciably longer anteriorly.

- ilerdina*. **L. ilerdina** Hew. (38 d), from Peru, which is regarded as type of the genus *Leucothyris*, differs superficially from *ilerdinoides* in the absence of the two vitreous spots at the end of the cell of the forewing.
- lerida*. **L. lerida** Kirby is similar to *kena*, but without the two apical vitreous spots. It flies on the Lower Napo.
- lerdina*. **L. lerdina** Stgr. (38 d), from Pebas on the Upper Amazon, is smaller than *ilerdina*. In it the two vitreous spots in the end of the cell and at the hinder angle of the forewing are united into a broad oblique band.
- lubilerda*. **L. lubilerda** Hsch., from eastern Colombia, is a similarly marked species, but may be recognised at once by the transparent vitreous spots, which in the other forms have a milky dusting.
- ilerda*. **L. ilerda** Hew., also from eastern Colombia, is a form similar to *ilerdina*, without the vitreous spot in the red-brown band.
- In the following forms the red-brown subapical band of the forewing is much narrower.
- sexmaculata*. **L. sexmaculata** Hsch. (38 d), from the Upper Napo in Ecuador, has 6 vitreous spots in the forewing, namely besides the two in the cell: one at the end of the cell, one at the hinder angle and 2 smaller ones at the distal margin. — In *confluens* Hsch., from the Napo, there are only 5 spots, and in *lota* Hew. (38 e) only 4. The latter form occurs at the base of the eastern Andes in Ecuador. It has a posteriorly forked, dark oblique band at the end of the cell, which in *confluens* is moreover connected with the inner margin, so that in the latter
- confluens*. a further vitreous spot is separated off. — *escura* Hsch. is a darkened form of *lota*, without the red-brown markings on the upper surface, and with brown-red instead of yellow-red colour on the under surface. The whitish dusting
- escura*. of the vitreous spots is weaker. — A form nearly allied to *escura*, from the Upper Amazon, which I call **praemona**
- praemona*. **form. nov.**, is distinguished by much broader black margins and bands. The costal and distal margins of the hindwing especially are much widened and leave in the disc only a vitreous longitudinal band, which is broader at the inner margin, as in *epicharme* (38 e).
- agarista*. **L. agarista** Fldr. (38 e). The red-brown colour is mostly much lighter than in the figure. This form may be recognised by the two large, connected vitreous spots in the apex of the forewing. It flies on the upper
- janarilla*. Rio Negro and the Upper Rio Napo. — **janarilla** Hew. is a very similar form from eastern Ecuador and Peru, without the red-brown colour on the upper surface, and without the whitish dusting in the disc of the hindwing.
- priscilla*. **L. priscilla** Hew. (38 f) and **gunilla** Hew., both from the Upper Amazon (Rio Juruá, Fonte Boa), are two rare, brightly coloured forms, with red-brown hindwing. *priscilla* has a submarginal band in addition to the dark distal margin on the hindwing. In *gunilla* only the commencement of this band is present in the apex. *priscilla* has in the dark brown forewing 4 vitreous spots and a basal triangle; in *gunilla* the vitreous spot at the hinder angle is wanting, the basal area is more extended and of a red-brown colour.
- gunilla*.
- tigilla*. **L. tigilla** Weym. (38 e) is a larger species from eastern Ecuador of similar appearance to *lota*, but without the fork of the oblique band and with broader wings.
- assimilis*. **L. assimilis** Hsch. is a very similar species from the same district, somewhat smaller, without the white spot at the costal margin and end of the cell of the forewing. The markings of the two forms also differ somewhat in other details. But they may be recognised especially by the neuration. The middle discocellular of the hindwing is considerably larger in *assimilis*, and the cell is consequently much larger.
- zelica*. **L. zelica** Hew. (38 f), from the western Andes of Ecuador, may be recognised by the yellowish colour of both wings. The pattern of the otherwise blackish apical half of the forewing consists of two subapical dots and two larger whitish spots at the end of the cell and the hinder angle. The hindwing is very broadly margined
- pagasa*. with black. — A similar form is **pagasa** Druce, from Panama and Costa Rica. The hindwing is like that of *zelica*, but the forewing has a broad band through the cell. The subapical spots are larger.
- aegle*. **L. aegle** F. (= *hippodamia* Hew.) (38 f). The wings are almost diaphanous with dark margins. In the forewing some oblique bands divide the vitreous area into a number of spots, namely besides the two in the cell: one each at the end of the cell and the hinder angle, as well as 2 smaller ones and 1—2 dots at the distal margin. A red-brown stripe traverses the distal margin of the hindwing. The species flies with the similar following form
- zarepha*. in Guiana. — **zarepha** Hew. (38 f) has at the end of the cell of the forewing a band-like row of spots to the hinder angle and 2 vitreous spots in the apex. On the under surface the white marginal dots are absent. Guiana.
- dolabella*. **L. dolabella** Hew. (38 e), from Bolivia, has a broad, white oblique band at the end of the cell of the forewing and a double spot at the apex; across the cell runs an incomplete, dark oblique band. The vitreous
- brisotis*. spots and the disc of the hindwing are dusted with white. — As **brisotis form. nov.** I designate another form, likewise from Bolivia, with narrow white oblique band on the forewing, especially at the end of the cell. The dark distal margin of the hindwing is strongly widened proximally.

I give the name of *flexibilis spec. nov.* to a species from northern Peru which is similar to *dolabella*. It is smaller and has a narrower whitish oblique band, constricted in the middle. At the hinder angle of the forewing is placed an oblong vitreous spot, as in *crispinilla*, from which *flexibilis* is distinguished by the double spot in the apex. — From Bolivia comes another very similar form, which I call *virina form. nov.* It has a white oblique band like *dolabella*, but the other vitreous spots are colourless, not dusted with white. At the hinder angle of the forewing there is a vitreous spot as in *flexibilis*, but the black oblique band across the end of the cell is quite narrow, linear from the median onwards.

L. perspicua Btlr. (38 e) is very similar to *janarilla*, considerably larger, with subapical band instead of the double spot, and also a pear-shaped spot at the hinder angle of the forewing. It flies with the allied *onega* and *epicharme* at the Upper Amazon. — *onega* Fldr. has a broader white oblique band on the forewing and the hindwing is black with a narrow, curved vitreous band behind the middle, which is shaded with dark at the inner margin. — In *epicharme* Fldr. (38 e) the vitreous band of the hindwing is broader, wedge-shaped, broadest at the inner margin.

L. amazona Hsch., from the Upper Amazon, is similar to the preceding, with uniformly broad oblique band on the forewing, without the vitreous spot at the hinder angle. — Another similar form, which I call *ramona form. nov.*, has colourless vitreous spots except for the white oblique band, the spot at the hinder angle being elongate-quadrate. The median band of the hindwing is narrowest in the middle, the broad costal margin forming an angle at the 2nd median vein. It flies near Sara-yacu on the Ucayali.

L. crispinilla Hpffr. (38 e), from eastern Peru, is distinguished from the preceding by whitish dusting and narrow black costal margin to the hindwing, which does not enter the cell.

A species very similar to the preceding, which I call *L. enania spec. nov.*, flies also in Peru. It is appreciably smaller and has different neurulation, as well as narrower bands and margins. Especially noteworthy is the black streak across the cell of the forewing, which is here placed in the prolongation of the 1st median vein, whilst in *crispinilla* it is nearer to the base.

L. didymaea Hew., from Bolivia, has a similar pattern to *virina*, without the double spot in the apex of the forewing. It may be recognised by the black oblique band across the end of the cell of the forewing, which forms a streak from the median to the distal margin, as well as by the narrow, uniformly broad distal margin of the hindwing.

In the following forms the band-like streak through the cell of the forewing is absent.

L. borilis spec. nov. I thus name a similar species to *didymaea*, from Pozuzo in South Peru, with the wings dusted with white, without the streak in the cell. The distal margin of the hindwing is much broader.

L. synnova Hew. (38 f). This rare and beautiful species is very strikingly distinguished by the orange colouring (in the figure this is too dark) from the otherwise similarly marked species, such as *ramona*, etc. According to BATES it only flies on the north bank of the Upper Amazon, near Tunantins.

L. quintina Fldr. (38 f) is said to come from Venezuela, I know it only from Bolivia and Peru. It has white-dusted wings with black margins and an oblique band at the end of the cell of the forewing, which is gradually narrowed posteriorly. — The very similar *alexina* Hew., from Peru and Bolivia, has colourless wings, only the subapical band of the forewing is dusted with white. The markings strongly recall *Ithomia ardea*, which, however, is distinguished by the neurulation.

Next follows another small group with broad, rounded wings and black streak through the cell of the forewing, of which *L. astraeca* Cr. (39 b) is often mistaken for some other species. The typical form comes from Guiana. It has a broad, black oblique band on the forewing, which is only forked shortly before the distal margin; also quite faint red-brown colour in the distal margin of the hindwing. — *thimei* Oberth. (= *flora thimei* Hew. Exot. But. f. 68), from the Rio Magdalena in Colombia, is very similarly marked, but has no red-brown on the upper surface and beneath only at the base. Moreover, the distal margin of the hindwing is narrower and uniformly broad. — *flora* Cr., from Cayenne and Surinam, is a larger form with broad margins and bands and also red-brown markings in the distal margin of the hindwing. At the distal margin of the forewing 2 distinct white spots are marked off by the branches of the oblique band. — On the Lower Amazon flies a smaller form of *astraeca*, with roundish apex to the forewing, which I call *antaxis form. nov.* It has a light red-brown, dark-bordered distal margin to the hindwing and a similar spot at the hinder angle of the forewing.

An extremely similar species from the Middle Amazon, which I call *L. stradopsis spec. nov.*, has different neurulation and more pointed apex to the forewing. The upper arm of the lower discocellular and also the middle discocellular are longer. The oblique band of the forewing is rather gradually narrowed beyond the 2nd median, the 3rd is not thickened,

In *L. egra* Hew. (39 b) the black oblique band of the forewing is very broad, runs on the 3rd median vein and is connected at the other side with the black inner margin. The species flies on the Amazons.

aquata. **L. aquata** Weym. (39 b), from Brazil, is similar to *astraea*, with narrower margins and bands. The oblique band at the end of the cell only extends a little beyond the inner angle. The black streak across the middle of the cell is said to be of uniform width in typical specimens. Many examples, however, occur in which it is wedge-shaped.

serdolis. In another species, which I call **L. serdolis** *spec. nov.*, a wedge-shaped oblique band runs from the end of the cell across the 3rd median vein, and the vitreous spots are dusted with white. The pattern otherwise the same as in *astraea*. This form flies on the Upper Amazon.

Here begins the 2nd principal group of *Leucothyris* with elongate, colourless wings, which bear delicate whitish spots. Of these one at the distal margin of the forewing between the 2nd and 3rd median veins is especially characteristic of the group, as it is placed so close to the distal border that the dark distal margin is always narrowed here. There are two similar whitish spots at the apex of the forewing. The neurulation of the hindwing is also very varied in this group. There occur both species with typical *Hyposcada*-neurulation and also very many in which the cell is considerably longer than in typical *Leucothyris*-species.

susiana. **L. susiana** Fldr. (38 g). This beautiful and rare species from the eastern Andes of Colombia and Ecuador has black wings with several rows of white vitreous spots. On the under surface the predominant colour is red-brown. The forewing has at the base an oblong spot, then follow 2 rows of white spots before and behind the end of the cell, and also 3 subapical spots and some white marginal dots. The hindwing shows in the disc a continuous white macular oblique band and large white double marginal dots. — *susanna* Stgr. is a very similar form from Colombia with smaller white spots and dots, but a broader yellowish oblique band on the hindwing.

cyrene. **L. cyrene** Latr. is similar to *susiana*, from the Upper Amazon and Peru. The position of the vitreous spots is somewhat different. The middle spot of the first row is absent and the band of the hindwing is widened at the inner margin. — A nearly allied form from Colombia, which I call **radina** *form. nov.*, has a double spot in the end of the cell of the forewing and behind it 3 vitreous spots. The oblique band of the hindwing is widened at the inner margin to the base. — *Napeogenes domiduca* Hew., from Bolivia, very closely resembles the *Leucothyris*-forms now under consideration, but belongs to the genus *Napeogenes*, as I have only recently been able to prove from typical specimens. It has a large basal vitreous area in the forewing and from the end of the cell to the hinder angle a broad macular band, divided at the costal margin. Cf. Additions, p. 165.

attalia. **L. attalia** Hew. (38 g) has a black spot in the end of the cell of the forewing and numerous vitreous spots in the apical half. The species flies in Bolivia and Peru. — **attalita** Hsch. is a much smaller form from Bolivia. The vitreous spots have a strong milky colouring and on the under surface the yellow-brown colour of *attalia* is here grey-brown.

taliata. **L. taliata** Hew., from Peru, has larger, contiguous vitreous spots in the disc of the forewing and a very broad vitreous band on the hindwing, as well as larger marginal dots on both wings.

solida. **L. solida** Weym. (38 g). Here the vitreous spot between the 2nd and 3rd median veins in the discal macular band of the forewing is the longest (in *taliata* it is the one between the 1st and 2nd veins). The large marginal dots are almost entirely absent. On the hindwing the vitreous band is narrower in the middle. — In *ab. completa* Hsch., which flies with the type in eastern Ecuador, the costal margin of the hindwing is black to beyond the cell, so that the vitreous band is narrower.

orestilla. **L. orestilla** Hew. (38 g) is the largest species of the true Ithomiids. The markings are similar to those of *solida*, with much larger vitreous spots. The third apical spot at the costal margin is absent. It flies in the eastern Andes of Colombia and Ecuador in thick mountain woods near the tree-limit at elevations of up to 3000 m.

valida. **L. valida** Hsch., from the borders of Peru and Bolivia, is the same size as *susiana* and resembles *completa*, without the white marginal spots on the upper surface. The small white dot between the end of the cell and the apex is in alignment with the two other subapical spots, and the vitreous spots at the hinder angle are larger.

fasciata. **L. fasciata** Hsch., from the Upper Pastaza in Ecuador, is smaller, with narrow black costal margin to the hindwing and spot across the end of the cell. It has a milky oblique band in the vitreous area of the hindwing, whilst in *solida*, which is otherwise similar, the whole disc is milky coloured.

deronda. **L. deronda** Hew. (39 a), from Peru and Bolivia, is distinguishable from the similar forms by the yellowish tinted forewing. In markings it is similar to the preceding forms, but the apex is much more narrowly black, so that the two apical vitreous spots are not defined proximally. — **derondina** (Stgr. i. l.) is a much smaller but otherwise extremely similar form from Bolivia with somewhat different neurulation. The second yellow spot at the costal margin of the forewing above is absent. The spot in the cell is narrower and in the ♀ the black spot is absent in the angle which the median forms with its 1. branch.

cytharista. **L. cytharista** Hew., from Peru, probably also belongs here. It is of the same size as *deronda* and has yellowish forewing with dentate distal margin and curved half-band across the end of the cell. The hindwing has a bluish white tone and broad distal margin, strongly dentate proximally, with large white dots. -

Under the name **L. athalina** (38 g) STAUDINGER united several similar forms. I regard as typical specimens according to STAUDINGER's figure those from Bolivia of which the ♀ bears a dark mark across the cell of the hindwing. The forewing is similar to that of *valida*, but the second white dot at the costal margin near the apex is absent. — The similar form from Colombia I call **tremona** *form. nov.* In the ♀ the dark mark on the median of the hindwing is absent and also the connecting triangle between the end of the cell and the inner margin. The half-band at the end of the cell is produced into a point at the 3rd median vein. — **banjana** Hsch. is the form from eastern Ecuador, which occurs at elevations of from 2—3000 m. The two apical vitreous spots are proximally bordered with black. The half-band at the end of the cell is as in *athalina*, but in the ♀ the dark mark on the median of the hindwing is absent. On the under surface the colour is brown-red, lightest in *tremona*: yellow-brown. — **santineza** Hsch. is a smaller form from Ecuador; it flies at elevations of from 1000—15000 m. The spot in the cell of the forewing in the ♂ is wedge-shaped, in the ♀ broader, with the extremity obtuse.

L. tabera Hew. (39 a), from the eastern Andes of Ecuador, has narrower half-bands across the end of the cell of the forewing and in the middle of the cell. The distal margin of the hindwing is very broadly edged with black. On the under surface the margins have dark brown-red markings. — In ab. **maerenda** Hsch. the apex of the forewing is broadly black with two vitreous spots. The hindwing has the distal half and the apex black.

The following forms have a narrower distal margin to the hindwing.

L. makrena Hew. (39 a), from Venezuela and Colombia, differs from the similar forms, such as *santineza*, etc., in the much narrower distal margin of the hindwing. The half-band at the end of the cell of the forewing is broad, the streak in the middle of the cell narrow. — **makrenita** Hsch. (39 a) is considerably smaller, it flies in eastern Ecuador. The markings are similar to those of *makrena*, behind the end of the cell of the forewing there is a white macular band.

L. baizana Hsch., likewise from the eastern Andes of Ecuador, may be recognised at once by the smoky brown colour and the long, narrow wings. The markings are similar to those of *makrena*. The dark brown distal border of the hindwing is proximally dentate at the veins.

L. quadrata Hsch. (39 a), from eastern Ecuador, is smaller than the preceding and may be recognised by the broad wings and the 2 vitreous spots in the apex of the forewing. The wings have a bluish white sheen.

L. amalda Hew. (39 b), from Colombia, has very similar markings, but differs notably in the red-brown colour in the distal half of the hindwing. It flies together with the very similar *Pseudoscada lavinia*, but is easy to recognise by the dark streak in the cell of the forewing. — **amaldina** (Stgr. i. l.) is a smaller, more weakly marked form, likewise from Colombia. Its hindwing is diaphanous except for a yellow-brown distal margin.

L. modesta Hsch., from western Ecuador and Colombia, has similar markings to *quadrata*. The apex of the forewing is rounded; the half-band at the end of the cell is short, triangular; the dark distal border of the hindwing narrow.

L. bioculata Hsch., from Bolivia, is likewise a similar form to *makrenita*; with 2 vitreous spots in the apex of the forewing and indistinct streak in the cell. Beneath the margins are yellow-brown, with only 2 white dots in the apex of each wing.

L. epimakrena Hsch., from Bolivia, is about the same size as *makrena* and has similar markings. It may be recognised by having the distal border of the hindwing proximally dentate at the veins and a dark streak at the end of the cell. The wings are elongate; the spot in the middle of the cell of the forewing wedge-shaped.

L. zea Hew. (39 b) is one of the few but peculiar Ithomiids which occur in Mexico. Prominent characters are the brown-red margins and the presence of only one vitreous spot in the apex of the forewing. — **vicina** Salv. is a similar form, also with brown-red margins, from Costa Rica. It is smaller, the margins in the apex of the forewing are narrower. The spot at the end of the cell is triangular; the streak in the middle of the cell narrower.

L. caucana Stgr. (39 b), from the Cauca Valley in Colombia, has narrower margins and patches than *makrena*. The black streak in the middle of the cell is often entirely absent.

L. phemonö Dbl. & Hew. (= *morphenoë* H.-Schäff.) (39 b), from Colombia and Venezuela, has rounded wings with narrow margins and a narrow streak in the cell of the forewing. The subcostal of the forewing is red-brown; the whitish patches at the apex and distal margin are indistinct. — **burchelli** Sand., from the Rio Tocantins, is said to be nearly allied to the preceding form, but to be distinguished by broader margins and patches. Especially the dark oblique band across the end of the cell is prolonged and then continued as a distinct stripe on the 2nd median vein to the distal margin.

- rubescens.* **L. rubescens** Btlr. & Druce (39 c), from Costa Rica, has the margins partly red-brown, as in *vicina*, but a broad black-brown apex to the forewing, and also a broad white oblique band.
- The following forms have no dark streak in the cell of the forewing.
- inelegans.* **L. inelegans** Hew., from Ecuador, is of the same size as *susiana* and has vitreous wings with dark distal margins, strongly dentate proximally, especially in the hindwing. Across the end of the cell of the forewing is placed a half-band, with process at the 3rd median vein. On the under surface the margins are red-brown with white distal-marginal double spots.
- fumata.* **L. fumata** Hsch., from the Cauca Valley, is of the same size as *makrenita* and has narrow borders to the slightly smoke-brown wings and narrow half-band at the end of the cell of the forewing. Beneath the margins are light yellow-brown.
- manora.* **L. manora** Schaus, from Central Brazil, is said to have transparent bluish white wings with blackish margins and veins. In the apex of the forewing a vitreous spot, at the end of the cell a whitish patch.
- sarilis.* As **L. sarilis** spec. nov. I designate a form from the Upper Amazon, similar to *graciella*, with 2 vitreous spots in the black apex of the forewing. The half-band at the end of the cell has a projection above the 3rd median vein; the whole of the 2nd vein is broadly black.
- graciella.* **L. graciella** Oberth. (= *victorina* Hew.) (39 c), from the Upper Amazon, and **victorina** Guér., from Venezuela and Colombia, are very much alike. They have a broad black apex and a broad white oblique band at the end of the cell. In *graciella* the veins in the white oblique band are completely covered, whilst in *victorina* the upper vein and half the second one appear black. — **padilla** Hew., from western Ecuador, is also very similar, with broader white oblique band, which reaches to the hinder angle, so that the 2nd median vein also is dusted with white. — **paula** Weym., from Central America, is likewise similar, with narrow white oblique band, broad, almost quadrangular, black spot at the end of the cell and red-brown costal margin, and also a red-brown spot at the hinder angle of the forewing and distal margin of the hindwing.
- estella.* **L. estella** Hew. (39 c), from eastern Ecuador, is a small species with broad black apex to the forewing and distal margin to the hindwing, the latter with a red-brown stripe, and also with a broad white oblique band in the forewing. On the under surface the dark margins have yellow-brown central stripes. — In Bolivia occurs a similar form, which I call **subosa** form. nov. It has a narrower white oblique band and narrower distal margin to the hindwing. Moreover, the whole disc of the latter is whitish, together with the veins; in *estella* only at the apex, the rest being colourless with black veins.
- Finally I refer here 2 new forms, which are very different from the preceding, but according to the neururation agree best with *Leucothyris*.
- ferra.* **L. ferra** spec. nov. (39 d) strongly recalls by its markings species of *Thyridia*, *Aprotopos* and *Dircenna*. The wings are almost colourless with dark brown margins and a transverse band across the end of the cell of each wing. In the middle of the distal margin of the hindwing there are 3 white dots. The antenna has yellowish club. On the under surface all the distal margins have white marginal dots as far as the apex. From southern Peru. — **thyridiana** form. nov. is a similar, larger form from Bolivia with black margins and bands and a triangular spot in the cell of the forewing. Otherwise the markings are as in the preceding. On the under surface a yellowish streak is placed behind the base of the hindwing.
- thyridiana.*

26. Genus: **Episcada** Godm. & Salv.

This also is only a genus of convenience, whose characters are not sharply defined. Properly the upper discocellular of the hindwing should be entirely absent in the ♂, but mostly it is still feebly present. The habitus of the species referred to *Episcada* is always very different from that of *Leucothyris* and approaches much more that of the following genus *Pteronymia*. The lower discocellular in *Episcada* appears to be always very distinctly angled, whilst in *Leucothyris* the anterior arm disappears in the dark costal-marginal stripe. The cell of the hindwing in typical species is almost equally long anteriorly and posteriorly.

The species of *Episcada* are mostly not easy to recognise as such, since superficially they closely resemble certain species of *Pteronymia*. Only the ♂♂ are more certainly distinguishable by the upper discocellular and radial of the hindwing. The few species of *Episcada* are scattered over the whole Neotropical region and are generally not very common.

- salvinia.* **E. salvinia** Bates (39 d), from Guatemala, has delicate, almost colourless wings with narrow brown margins and half-band at the end of the cell of the forewing, and also a white spot at the costal margin. On the underside the margins are lighter yellow-brown. — **rufocincta** Salv., from Mexico, is a similar form with yellow-brown margins, blackish streak at the inner margin of the forewing, and without white patch at the end of the cell.
- clausina.* **E. clausina** Hew. (39 d), from Bolivia, has dark brown margins and half-band with yellow spot at the end of the cell. The costal margin of the hindwing is yellow beneath. The subcostal of the forewing is red-brown; in the ♀ also the inner margin. — In Central Brazil occurs a very similar form, which I call **striposis**
- striposis.*

form. nov. It has additional yellow dusting in the end of the cell of the forewing and on the hindwing. On the under surface the margins are darker red-brown with blackish borders.

E. carcinia Schaus, from South Brazil, is said to have colourless wings with narrow margins and a *carcinia*. white spot behind the cell at the costal margin of the forewing. — In **pasena** Schaus, from Central Brazil, the *pasena*. body is said to be grey beneath; the transparent wings with very narrow brown margins. Forewing with narrow streak at the end of the cell and a transparent streak at the costal margin. Hindwing with 1—2 white dots at the apex of the under surface.

E. mira Hew. (= *segesta* Weym.) (39 d), from eastern Ecuador, has a very broad yellow half-band at *mira*. the end of the cell of the forewing and is otherwise similar to *clausina*.

E. hymenaea Prittw. (39 e), from Central Brazil, has brownish margins and half-band at the end of the *hymenaea*. cell of the forewing and in addition a whitish patch. Diaphanous spots are placed at the distal margin of both wings. On the under surface the margins are lighter. — **hymen** Hsch. (39 e), from southern Bolivia, *hymen*. is smaller with broader margins and half-band at the end of the cell, and also a yellow oblique band. Subcostal red-brown at the base. The median, the end of the cell and the hinder angle of the forewing are dusted with yellow, and also the lower radial of the hindwing and a stripe at the costal margin on the under surface.

E. sulphurea Hsch., from the border of Peru and Bolivia, has longer wings, broader yellow oblique *sulphurea*. band and broader dark brown margins. The yellow dusting is extended over the cell of the forewing and the greater part of the hindwing; on the other hand it is absent at the costal margin of the hindwing beneath.

E. sao Hbn. (39 d), from Brazil, has broader dark margins and yellow patch at the end of the cell of *sao*. the forewing. Base of the under surface of the hindwing yellow-brown, distal margin with 4 white crescents.

— **obscurata** F. is according to BUTLER a dark form of the preceding. *obscurata*.

E. sylpha Hsch. (39 e), from Venezuela, is similar to *Miraleria sylvella*, but is smaller and has different *sylpha*. neurulation. The wings are diaphanous with brownish margins; at the costal and inner margins of the forewing with yellow-brown, and the same at the inner angle of the hindwing. At the end of the cell of the forewing a yellow patch.

E. polita Weym. (39 e) is very similar to *Pteronymia aletta*. The wings are dark-shaded with dark *polita*. brown margins. The inner margin and the subcostal of the forewing, as well as the veins in the disc of the hindwing, are yellow-brown. Besides the yellow spot at the end of the cell both wings have further yellowish patches at the distal margin and in the end of the cell. *polita* flies together with *Pteronymia aletta* in Colombia.

E. cabenis Hsch. is somewhat larger, with colourless wings, dark brown margins and white half-band *cabenis*. behind the brown one at the end of the cell. On the under surface the margins are yellow-brown, dark-margined with 1—2 dots in the apex of both wings. It flies like the similar *helena* Hsch. in eastern Colombia. The *helena*. latter is still larger, with narrower margins, triangular spot at the end of the cell of the forewing and broader white half-band.

E. sidonia Hsch., from southern Peru, has more pointed wings; cell of the hindwing with long recurrent *sidonia*. vein. The white patch at the end of the cell of the forewing is only distinct at the costal margin and on the radials. On the under surface the margins are deep ochreous coloured, without white dots in the apex.

E. cora (Bang-H. i. l.), from Bolivia, is larger than the similar *tigidella* Hew. (39 e), from eastern Ecuador. *cora*. *tigidella*. The wings in *cora* are slightly brownish; behind the end of the cell of the forewing, at the distal margin and at the inner angle of the hindwing yellowish. Across the end of the cell of the forewing there is a broad brown wedge-spot; in *tigidella* there is only a very narrow dark mark here and behind it a whitish patch. On the under surface the margins in *cora* are light yellow-brown, in *tigidella* brownish with white dots in the apex of the forewing and at the distal margin of the hindwing.

E. canilla Hew. (= *canaletta* Stgr.) (39 e) has elongate wings with yellow dusting, except in the apex. *canilla*. The margins are dark brown; in the ♀, especially in the hindwing, much broader. On the under surface the margins are brown-red, with dark borders; at the base of the hindwing yellow; with white double spots in the apex of the forewing and at the distal margin of the hindwing.

E. perasippa Hew. (39 e) is a very large, little marked species from Ecuador and Colombia. The wings *perasippa*. are yellowish, vitreous with narrow brown margins and a streak across the end of the cell of the forewing. The subcostal of the forewing and the underside of the margins are yellow-brown.

E. dirama Hsch. (39 f), from Bolivia, is smaller, with broader streak at the end of the cell and yellow *dirama*. spot behind it. The costal margin of the hindwing is yellow on the under surface. — **alidella** Hew., from Co- *alidella*. lombia, is a very similar form, which also much resembles *Pteronymia alida*. HEWITSON has noticed that there is a difference between the two in the neurulation, which also appears to be constant for other species of *Episcada* and *Pteronymia*: in *alida* the lower arm of the lower discocellular of the forewing is the longer; in *alidella* it is the upper one. *alidella* has broader wings with dark margins and broad yellow half-band at the end of the cell of the forewing. In the ♀ there are further several yellow patches at the distal margin.

E. scantilla Hew., from eastern Ecuador and Colombia, has similar wing-form to *dirama*, a white spot *scantilla*. at the end of the cell of the forewing and white patches at the distal margins.

- paradoxa*. **E. paradoxa** Stgr., from the Cauca Valley, is a large species with colourless wings and narrow borders. only the costal and inner margins of the forewing have broad margins, the end of the cell is without marking. Similar species are *Napeogenes flossina* (35 g) and *Hymenitis quinta*.
- praestigiosa*. **E. praestigiosa** Hsch. closely resembles *Dismenitis cleonica* (41 e), but is distinguishable at once by the acutely angled lower discocellular of the hindwing. The forewing is slightly shaded, the hindwing tinged with yellowish; with white patches at the end of the cell of the forewing and the distal margins. The end of the cell of the forewing is in the ♂ very narrowly, in the ♀ broadly coloured with brown. The distal margins are proximally produced into points at the veins. — A similar, smaller species from Colombia, which I call
- lobusa*. **lobusa** spec. nov., has a yellowish patch at the end of the cell, more weakly dentate distal margins, narrower marks at the end of the cell and at the distal margin of the hindwing; on the under surface large white double spots, which are entirely absent in *praestigiosa*.
- philoclea*. The following **E. philoclea** Hew. (39 d), from southern Brazil, has already quite the appearance of a *Pteronymia*, but still a distinct upper discocellular and radial in the hindwing of the ♂♂. It has yellowish wings with black margins, half-band across the end of the cell and yellowish patch beside it. In the disc of the hindwing the veins are also yellowish. On the under surface the margins are dark brown-red, with white double spots at the distal margin of the hindwing and the apex of the forewing. The costal margin of the hindwing is yellowish with reddish spot at the base. The species recalls *Ceratinia eupompe* (35 d), with which it occurs
- munda*. together. — **munda** Weym. is a form with broader margins and connecting streak between the half-band and the inner margin of the forewing.

27. Genus: **Pteronymia** Btlr. & Druce.

To this genus should rightly belong only species in which the upper discocellular of the hindwing is absent and in the ♂♂ of which at least the greater part of the upper radial is coincident with the subcostal. But when one has only female specimens it is often difficult to determine whether the species belongs to *Pteronymia* or *Episcada*, for superficially forms of the two genera are often very similar. There are no distinctive external characters for the whole genus, as in *Leucothyris*. The commonest pattern is that shown in *zerlina* (39 g); yet there are also gay-coloured species, such as *latilla*, which recall *Episcada*. The forms belonging to *Pteronymia* are rather numerous. They often occur in numbers, are mostly widely distributed and therefore not rare. A few even occur in great profusion, such as *zerlina*, *simplex*, *artena*, *euritea*. The Andes from Bolivia to Colombia produce the largest number of species.

- latilla*. **P. latilla** Hew. (39 f), from Venezuela and Colombia, has transparent yellowish wings with yellow-brown dusting, especially at the base of the forewing and the inner angle of the hindwing. The apical half of the forewing is blackish with 2 yellow macular bands. The margins of both wings and a spot in the cell
- albicans*. of the forewing are also blackish. — In ab. **albicans** Hsch. the yellow macular bands are whitish and the end
- nigricans*. of the cell of the forewing and the apical third of the hindwing are dusted with yellow. — In ab. **nigricans** Hsch. the spot in the cell, the costal and inner margin, and also the end of the cell of the forewing and a band on the median are broadly black-brown. It flies in Colombia.
- barilla*. **P. barilla** Hsch. is a form similar to *latilla*; from western Ecuador. It has more delicate colouring, smaller yellow dots, a red-brown base to the inner margin of the forewing, slightly reddish colour on the hindwing and much smaller white marginal dots in the distal margin of the hindwing beneath.
- picta*. **P. picta** Salv., from Colombia, has a blackish forewing, the base of the cell is brown, the middle yellow, across the end is placed a black spot. In the distal half there are 2 yellow macular bands consisting of 4 or 5 spots. The hindwing is yellow, with broad black distal margin and brown streak at the inner angle.
- notilla*. **P. notilla** Btlr. & Druce (39 f ♂, ♀). The ♂ has a similar pattern to *latilla*, but paler, also the dark spot in the cell is absent. In the ♀ the colouring is much lighter; the cell shaded with dark and the hindwing unicolorous. red-brown. This is the Central American form of the group, from Costa Rica. It has black
- olyrilla*. antenna, while that of the preceding forms has a yellowish club. — **olyrilla** Btlr. & Druce, likewise from Costa Rica, recalls the similar *Dircenna olyras* by the vitreous longitudinal band in the hindwing, and differs principally in this from the preceding form.
- donella*. **P. donella** Fldr., from Colombia, has a red-brown basal third to the forewing and a differently shaped half-band at the end of the cell. The hindwing as in the ♀ of *notilla* is uniformly red-brown with broader dark distal margin.
- donata*. **P. donata** (Bang-H. i. l.) is a smaller form from Panama and Costa Rica with lighter colour and very broad, angled yellow band to the forewing, which extends from the costal margin across the end of the cell to the inner margin. Otherwise the markings are similar to those of *donella*.
- fulvimargo*. **P. fulvimargo** Btlr. & Druce, from Costa Rica, is said to be similar to *Episcada obscurata* and *Dircenna olyras* (36 e). The forewing is transparent with faint yellowish macular band at the end of the cell and the distal

margin, and also with blackish half-band at the end of the cell. The hindwing has dark margins and also a red-brown sub marginal band and red-brown veins. ♂ and ♀ are coloured almost alike.

P. fulvescens Godm. & Salv., from Costa Rica, is said to be similar to *latilla* and *fulvifrons*. The *fulvescens*. upper radial of the hindwing is entirely absent. The club of the antenna is yellow.

P. splendida Hsch., from eastern Colombia, of which only the ♀ is known to me, has the fore- *splendida*. wing similar to that of *notilla*-♀, with broader black margins and dark spot in the middle of the cell. The hindwing is slightly yellow-brown, with a yellow spot at the apex and very broad black distal margin. The club of the antenna is yellow-brown.

P. dispar Hsch. (39 f) has transparent yellowish wings with black margins and half-band at the end *dispar*. of the cell, which beneath are variegated with brownish. Club of the antenna yellow-brown. In the ♀ the subcostal and median of the forewing, as well as the veins in the disc of the hindwing, are yellow-brown. The species flies in Colombia and Venezuela.

P. alinda Fldr., from Venezuela, is said strongly to recall *donella* in the markings. Forewing in the *alinda*. cell yellow-brown, subcostal and median red-brown, the other margins black-brown. In the blackish apical area 2 yellowish macular bands. Hindwing dusted with yellow-brown, with red-brown veins and broad blackish distal margin.

P. veia Hew. (39 g), from Venezuela and Colombia, has a broad yellow oblique band at the end of *veia*. the cell of the forewing and yellow-brown margins on the under surface with large white crescents. In the ♀ the margins are broader and a dark spot is placed at the end of the median of the forewing. — In ab. **brunnea** (Stgr. i. l.) the subcostal and median of the forewing and also the veins in the disc of the *brunnea*. hindwing are yellow-brown. The yellow oblique band is still broader and more brightly coloured.

P. zerlina Hew. (= *arinia* H.-Schäff.) (39 g) has vitreous wings with blue-grey sheen and dark *zerlina*. brown margins; only the costal margin of the forewing is red-brown. At the dark band at the end of the cell and at the distal margin of the forewing there are whitish patches. In the red-brown margins of the under surface are placed at the apex of the forewing single, and at the distal margin of the hindwing double white dots. In the ♀ the inner margin and the half-band of the forewing are connected by a dark triangle. — In a local form from southern Peru, which I call **tamina** *form. nov.*, the club of the *tamina*. antenna is yellow-brown. The basal half of the cell is shaded with dark; the apical half of the forewing is yellowish and the disc of the hindwing has bluish white sheen. On the under surface the white dots are much smaller. — **hara** Hew. is a local form of *zerlina*, from Ecuador, with whitish patches behind the *hara*. end of the cell and at the distal margin of the forewing. The subcostal is red-brown.

P. lincera H.-Schäff. (39 g) has transparent yellow-brown wings, with yellowish patches at the end *lincera*. of the cell and at the distal margin of the forewing. Subcostal and median are light red-brown. Otherwise the markings are similar to those of *zerlina*. Eastern Ecuador and Colombia. — **alina** (Stgr. i. l.) is *alina*. a form similar to *zerlina*, from Bolivia, with red-brown, dark-edged margins on the upper surface, light yellow-brown beneath; with yellowish patches in the end of the cell, behind the cell, at the distal margin of the forewing and at the apex of the hindwing. In the ♀ the margins are proportionately broader.

P. pronuba Hew., from western Ecuador, has colourless wings with black margins and black-white *pronuba*. half-band at the discocellular. Subcostal and median are red-brown at the base. In the ♀ both the margins and the white half-band are much broader.

In **P. tucuna** Bates (39 g), from the Upper Amazon, the dark-margined wings are provided with *tucuna*. numerous yellow dots, namely in and behind the end of the cell, at the distal margin and hinder angle of the forewing, and also in the disc of the hindwing. The black antennae have yellow-brown clubs. — **tanampaya** (Stgr. i. l.), from Bolivia, has narrower wings. The whole cell of the forewing and the *tanampaya*. disc of the hindwing are dusted with yellow. The margins beneath are dark red-brown, in *tucuna* yellow-brown. — **bueya** (Bang-H. i. l.) is very similar to the preceding, but with red-brown subcostal and red- *bueya*. brown margins on the underside. It likewise flies in Bolivia.

P. zabina Hew. (40 b), from Colombia and Ecuador, has broader wings with smaller yellowish dots *zabina*. at the end of the cell and the distal margin of both wings. Antenna black; subcostal and a narrow inner-marginal stripe are red-brown. — In ab. **brunneata** Hsch. the median and the veins in the disc of *brunneata*. both wings are also red-brown. At the end of the cell of the forewing there is a yellow half-band.

P. huamba *spec. nov.* I call a small form similar to *lincera*, also from the eastern Andes of Ecu- *huamba*. dor, with slightly yellowish wings and faint yellow-brown patches at the end of the cell and distal margin of the forewing. The margins are black-grey, only the subcostal of the forewing slightly yellow-brown. The white double spots at the distal margin of the hindwing are very large. — **oneida** Hew. *oneida*. (39 g), from Colombia and Ecuador, is somewhat larger, with more brightly coloured wings. The distal margin of the hindwing is proximally dentate, especially in the ♀. There is a dark, isolated spot in the disc of the forewing at the end of the cell. The subcostal is broadly yellow-brown.

inania. **P. inania** Hsch. is a similar, larger species with broader wings and deep black-brown margins. Behind the end of the cell is placed at the costal margin an oblong yellow-brown spot. On the under surface there are numerous roundish white dots in the distal margin. This species, like the preceding, comes from the border of eastern Ecuador and Colombia.

serrata. **P. serrata** Hsch. has still larger and broader, slightly yellowish wings with strongly dentate distal border. The half-band at the end of the cell of the forewing is proximally widened. On the under surface there are quadrate, yellow-brown, dark-margined spots at the distal margin of the hindwing between the white double spots. This species flies with *Dismenitis theudelinda* (41 d) and other similar forms in the mountain forests of the eastern chain of the Cordilleras of Ecuador at elevations of from 2—3000 m.

teresita. **P. teresita** Hew. (40 a, b), from eastern Ecuador, has broad wings, almost colourless in the ♂, with narrow dark margins. In the ♀ the wings are dusted with yellowish, especially the hindwing. The latter has much broader distal border than in the ♂. On the under surface the margins are dark red-brown, with white dots in the apex of the forewing and at the distal margin of the hindwing.

evonia. In **P. evonia** Hsch., from Colombia, with shorter wings, the ♀ is of a yellow-brown colour, especially in the cell and at the end of the median of the forewing, and also at the proximal border of the costal and distal margins and on the veins in the disc of the hindwing. The antenna is black. The distal margin of the hindwing very broadly black.

sulmona. **P. sulmona** Hew., from Ecuador, is said to be similar to *teresita*, with narrower margins and black antenna. The base of the forewing and the hindwing are dusted with red-brown. On the under surface there is a white spot in the apex of each wing and the base of the hindwing is yellow.

suesa. **P. suesa** Hew., from Ecuador, has transparent wings with yellowish sheen and narrow brown margins and half-band across the end of the cell of the forewing. The club of the antenna is yellow-brown. On the under surface the margins are yellow-brown, with 2 white dots in the apex of the forewing and a row of double dots at the distal margin of the hindwing.

thabena. **P. thabena** Hew. (40 a), from the eastern ridge of the Andes in Ecuador, has broad, transparent wings, the forewing with yellowish, the hindwing with bluish sheen. Unfortunately only ♀♀ are known of this and the following similar forms, so that the genus cannot be exactly fixed. The marking recalls forms of *zerlina*. The distal margin of the hindwing especially is very broad, and on the underside, where it is red-brown, provided with whitish double dots. The antenna has yellow-brown club. — A local form from Bolivia, which I call **stantis form. nov.**, is distinguished by a narrow black half-band at the end of the cell of the hindwing. — From Ecuador comes another similar form, **aegineta** Hew. It has the distal margin of the hindwing strongly dentate proximally and a proximally widened half-band at the end of the cell of the forewing. — **cleobulina** Hew., from Bolivia, probably also belongs here. It has the hindwing like *thabena*, but in the cell of the forewing in addition a black bar, and at the black distal margin a projection in the direction of the somewhat prolonged half-band at the end of the cell.

denticulata. **P. denticulata** Hsch. (40 b), from Bolivia, has black margins and half-band at the end of the cell of the forewing; the distal margins are proximally dentate. The club of the antenna is yellow-brown. — In *dispaena*, **dispaena** Hew. (40 a), from the same district, the margins are brown; subcostal of the forewing reddish; antenna black. In the ♀ the margins are broader and partly red-brown.

alida. **P. alida** Hew. (40 a), from Venezuela, has narrower margins and a broad yellow half-band behind the uniformly broad half-band at the end of the cell. It closely resembles *Episcada alidella*.

calgiria. **P. calgiria** Schaus (? = *diracennoides* Stgr. i. l.), from Bolivia, is said to have transparent yellowish wings, with narrow dark brown margins and veins, and also curved half-band at the end of the cell of the forewing; behind this there are yellowish spots at the costal and distal margins; also at the base and in the end of the cell of the forewing. The distal margin of the hindwing is broadest at the 2nd median vein and in the apex. Club of the antenna yellow-brown.

tigranes. **P. tigranes** Godm. & Salv. (40 b), from Central America, has colourless wings with narrow dark margins, somewhat broader in the ♀; in the forewing red-brown subcostal, and also a broad dark and white half-band at the end of the cell. — **timagenes** Godm. & Salv., from Mexico, at elevations of up to about 2000 m., differs from the preceding by the red-brown margins, only the inner margin of the forewing is blackish. The half-band at the end of the cell is much smaller. — **alcmena** Godm. & Salv., from Guatemala, is somewhat smaller, with broader, reddish margins. The dark and the white half-band at the end of the cell are larger and more obliquely placed.

adina. **P. adina** Hew., from Venezuela, is a similar species to *tigranes*, without red-brown subcostal and with oblong white spot at the costal margin of the forewing. The costal margin of the hindwing is strongly arched, the middle discocellular very long and curved.

eulyra. **P. eulyra** Fldr., from Venezuela, is said to be similar to *Episcada alidella*, but much smaller, with white submarginal spots on the under surface.

P. apuleia Hew. (? ♀ = *santanella* Hsch.) (40 a), from eastern Ecuador, is very similar to *Mira- apuleia*, *leria sylvella* (40 e), but may be known by the strongly angled lower discocellular of the hindwing. The margins, except the yellow-brown costal margin of the forewing, are narrowly dark brown; the half-band at the end of the cell of the forewing is somewhat curved and pointed.

P. granica Hew. is a similar species, also from Ecuador; but the half-band at the end of the cell is absent. On the under surface the base of the costal margin of the hindwing is yellow and each wing has 2 whitish dots in the apex.

P. ticida Hew. (40 e), from eastern Ecuador, has narrow wings with black margins; at the base of *ticida* both wings yellowish dusting. It closely resembles *Episcada tucidella* (39 e). But on the under surface the margins are black, only the base of the hindwing is yellow. In the apex of the forewing are placed 3, at the distal margin of the hindwing 5 oblong white dots. — **yungava** Hsch. is a similar form from Bolivia. *yungava*. The margins are brownish; subcostal of the forewing red-brown, on the underside yellow-brown with only one white dot in the apex of the hindwing.

P. starkei Stgr., from Venezuela, has broader wings and in addition to the usual dark markings and *starkei*, the half-band at the end of the cell an indistinct bar in the cell of the forewing. In other respects this form approaches *adina*. — A form from western Ecuador, similar to *adina* and *starkei*, which I call **semonis** form. nov., has broad vitreous wings with narrow dark margins and red-brown subcostal, as *semonis*, well as dark half-band and whitish spot at the costal margin of the forewing. On the under surface very minute whitish dots are placed in the dark distal border of the yellow-brown margins.

P. ladra Stgr., from Ecuador, has similar wing-contour to *ticida*. The margins are brown above, *ladra*, yellow-brown beneath except the yellowish costal margin of the hindwing. The end of the cell of the forewing has no markings.

P. minna Schaus, from Bolivia, is said to have transparent wings of 55 mm. expanse; with narrow *minna*, dark margins and a yellow streak at the costal margin of the forewing, which is continued in a patch at the end of the cell. There are also yellowish patches at the distal margin. The subcostal of the forewing is red-brown. On the hindwing the cell and the inner margin are dusted with yellowish. On the under surface the margins are red-brown, with 3 white, dark-edged spots in the distal margin of the hindwing.

P. ilsia Schaus, also from Bolivia, is said to be smaller, with broad brown and white half-band at *ilsia*, the end of the cell of the forewing; apex broadly brown.

P. medellina Hsch. (40 e), from Venezuela and Colombia, is a smaller species with fairly uniformly *medellina*, broad dark margins and triangular half-band as well as white spot at the end of the cell of the forewing. In the basal part both wings are dusted with yellowish. — **ozia** Hew. is a very similar form from Ecuador, *ozia*, with yellowish club to the antenna.

P. antisao Bates (40 d), from the Upper Amazon, has a sulphur-yellow oblique band at the end of *antisao*, the cell of the forewing to the distal margin. In the ♂ the median and subcostal of the forewing are only slightly yellow-brown, in the ♀ very broadly; here also the veins in the disc of the hindwing, as well as a more or less broad stripe in the dark distal margin, are yellow-brown.

P. simplex Salv. (40 b), from Costa Rica and Panama, has delicate wings with narrow brown mar- *simplex*, gins; yellow-brown subcostal and white spot at the narrow half-band of the forewing. On the under surface the veins are yellow-brown with indistinct dots at the apex. In the ♀ the margins are broader, half-band and white spot larger. Before the distal margins are placed whitish dots.

P. nepiscada Hsch., from southern Peru, is a similar, smaller species, which recalls forms of *Epi- nepiscada*, *scada*. Subcostal and median of the forewing are broadly yellow-brown. The spot at the end of the cell is yellowish. On the under surface an elongate yellow-brown spot is separated off at the costal margin by sulphur-yellow bordering and there are yellow dots in the apex of both wings.

P. sylvo Hbn., from Guiana, Venezuela and Brazil, in an insignificant-looking species, similar to *sylvo*, *alissa*, with wedge-shaped dark spot at the end of the cell of the forewing and white spot at the costal margin, as well as a streak at the end of the upper discocellular and a whitish patch in the hinder angle. — **carlia** Schaus, from Central Brazil, is probably, if not the same, at least a very similar form. *carlia*.

P. hemixanthe Fldr. (40 d), from Central Brazil, has the proximal half of both wings strongly *hemixanthe*, dusted with yellow. In this it resembles the smaller **euritea** Godt. (= *eudema* Godt.) (40 d), from the same *euritea*, district. The latter has, however, dark bands across the end of the cell and at the inner margin of the forewing, which are absent in *hemixanthe*; the present species on the other hand has a large reddish dot at the base of the hindwing beneath.

P. cotytto Guér. (40 c), from Central America and Mexico, has a broad black-brown apex to the *cotytto*, forewing and a broad half-band at the end of the cell, together with a white oblique band, which extends to the distal margin. The subcostal is red-brown. — **parva** Salv., from Costa Rica, is smaller than *parva*, *cotytto*, with narrower black apex to the forewing.

- fizella*. **P. fizella** Bdv., from Guatemala, is said to be very similar to *Ithomia agnosia* (37 f), with the margin of the forewing widened towards the apex and quadrate spot at the end of the cell. The white oblique band reaches the distal margin.
- artena*. **P. artena** Hew. (40 c) is said to come from Mexico, but a similar form is common in the eastern Andes from Colombia to Peru. *artena* has about the size and appearance of *tigranes* and *adina*. The black half-band at the end of the cell of the forewing is proximally forked, the white band ends at the third median vein. In the apex of the margins, which are red-brown beneath, are placed in the forewing 2 white dots, in the hindwing only one. — **olimba** Hsch., from southern Peru, is distinguished by a yellow base to the hindwing beneath and yellow underside to the abdomen, which is grey in *artena*.
- derama*. **P. derama** Hsch., also from the border of Peru and Bolivia, recalls *Pseudoscada salonina* (41 b). The wings are diaphanous with narrow margins. Across the end of the cell of the forewing is placed a wedge-shaped black spot and towards the apex a delicate yellow-white half-band, cut off at the 3rd median vein. On the under surface the margins are brown-red with 3 whitish dots in the apex of the forewing.
- afrania*. **P. afrania** Hpfr., from Bolivia, resembles *Miraleria sylvella* (40 e) and *Episcada salvinia* (39 d), without the red-brown colouring of the subcostal and median of the forewing. The narrow black margins are broadest in the apex and at the inner margin of the forewing. Beside the narrow, uniform black band at the end of the cell is placed a similar white one.
- apia*. **P. apia** Fldr., from Colombia, is similar to *tigranes*, with narrow margins and pointed dark half-band at the end of the cell of the forewing, and also a broad white one beside it. Subcostal red-brown. On the underside the costal margin of the hindwing is yellowish at the base.
- asopo*. **P. asopo** Fldr., from Venezuela and Colombia, is smaller than *artena*. The half-band at the end of the cell of the forewing is triangular; the white patch beside it proportionally broader. On the under surface there are 3 whitish spots in the apex of the forewing, 2 in that of the hindwing, as well as 3 indistinct ones at the distal margin. — **asellia** Hpff. (= andreas Weeks) (40 c), from Peru and Bolivia, is a similar form with the triangular spot at the end of the cell broader costally and beneath not blackish but rust-brown. Moreover the white marginal spots are absent and the 2nd median vein of the forewing is dark-margined. — In **aselliata** Hsch., from Ecuador, the white oblique band of the forewing is broader and reaches the 2nd median vein; also the white patch at the hinder angle is larger and in the ♀ united with the oblique band.
- alissa*. **P. alissa** Hew. (40 c), from western Ecuador, has a somewhat curved half-band at the end of the cell of the forewing and a small, white, black-edged spot at the costal margin. The apex of the forewing is more strongly rounded. — In **alissana** Hsch. the forewing has also a broad white oblique band, which, however, is semitransparent and not sharply cut off at the 2nd median vein, as in the similar *aselliata*. It flies likewise in western Ecuador.
- restilla*. **P. vestilla** Hew., from the Upper Amazon, has broader dark margins; the dark oblique band at the end of the cell is continued beyond the 2nd median vein to the distal margin. Behind it follows towards the apex a yellow oblique band. There is in addition yellow dusting in the end of the cell and at the hinder angle of the forewing, as well as in the anterior half of the hindwing. — In **ucaya** Hsch., from the Ucayali River, the yellow oblique band is whitish. — **sparsa** Hsch. is another form of *restilla*, from the Upper Napo in Ecuador. The yellow dusting of the wing is much stronger, especially in the whole of the hindwing, where also the veins stand out strongly yellow.
- laura*. **P. laura** Stgr. (40 d), from Colombia, is one of the few brightly coloured small species. It is similar in colouring to *Hypoleria vanilia* (40 g) and *Pseudoscada lavinia* (41 b). The half-band at the end of the cell is somewhat emarginate towards the apex and encloses a white patch. In the dark shaded apical area of the forewing are placed in addition a number of whitish dots at the distal margin and in the disc. The hindwing, especially at the distal margin, is red-brown (more strongly in the ♀) and with dark margins at the apical half.
- aletta*. **P. aletta** Hew. and **agalla** Godm. & Salv. (40 d) are 2 very similar forms, the former from Colombia and Venezuela, the latter from Panama and Costa Rica. *agalla* has a sharply defined yellow oblique band at the end of the cell of the forewing and roundish spots before the distal margin. In *aletta* the oblique band is composed of indistinct spots, between which the lower radial remains dark. On the yellow-brown hindwing the veins in *agalla* are bright red-brown, in *aletta* blackish in the distal half. Both forms have a broad red-brown inner margin to the forewing, whilst in a third form, **alopec** Godm. & Salv., from Panama and Venezuela, which is said to be otherwise similar to *aletta*, the inner margin remains blackish. Another species similar to these forms is *Episcada polita* (39 c).
- lilla*. **P. lilla** Hew. (40 c) has in addition to a yellow oblique band yellow dusting in the cell of the forewing and the costal half of the hindwing, and yellow dots at the distal margin of the forewing. On the under surface the margins are brown with yellow-brown markings, only the base of the hindwing is reddish yellow-brown. In the apex of the forewing are placed beneath 4 white dots, in the distal margin of the hindwing 5 oblong double dots. In western Ecuador at the foot of the Andes.

P. primula Bates, from the Upper Amazon, is a species similar to *vestilla*; the dark oblique band at the end of the cell is forked at the 2nd and 3rd median veins. The vitreous parts of both wings are for the most part dusted with yellow. The distal margins are broadly blackish brown, broadest in the apex of the forewing and the middle of the distal margin of the hindwing; on the under surface they are suffused with light brown, yellow-brown at the base and the inner angle of the hindwing. — **tenuis** Hsch. (40 c), from Colombia, is a similar form with delicate wings. Between the 2nd and 3rd median veins of the forewing is placed a triangular additional yellow spot. The yellowish oblique band is arc-shaped. On the under surface the margins are paler and in the distal margin of the hindwing there are no white dots as in *primula*.

P. auricula Hsch. (40 c), also from eastern Colombia, is larger, with broader black margins. The proximal edge of the distal border of the hindwing is nearly straight, not parallel to the outer edge. On the under surface the edges are dark, except at the end of the cell of the forewing and at the costal and distal margins of the hindwing, where they are yellow-brown.

P. glauca Hsch., from western Ecuador, recalls *Leucothyris quadrata*, but the vitreous spots in the apex of the forewing are absent. The wings have a strong blue-white sheen. The oblique band at the end of the cell is forked at the median veins. At the costal margin there is only one small whitish spot. On the under surface the margins are red-brown, dark-edged; with 4 white dots in the apex of the forewing, and 5 in the apex and distal margin of the hindwing.

28. Genus: **Miraleria** Hsch.

Here belong only a few forms, which may be recognised by their having the end of the cell straight in the hindwing. The lower and middle discocellulars are of equal length, weakly curved and alone closing the cell, whilst both the upper discocellular and the upper radial are absent in the ♂. The ♂ has an oblong scent-spot, which, as in *Hypoleria*, is not closed distally. The known forms are plain-looking, medium-sized butterflies, and occur only in the north-west of South America; they are not rare.

M. cymothoë Hew. (40 c), from Venezuela and Colombia, has colourless wings with brown margins, of which the distal ones are proximally dentate. The subcostal of the forewing is red-brown; the costal margin of the hindwing and all the margins on the under surface are yellow-brown. Beside the brown half-band of the forewing is placed a whitish band and in the apex of both wings on the under surface 2 whitish dots. — In ab. **flavomaculata** Hsch., from Venezuela, the band at the end of the cell is yellow, and also the dots on the underside.

M. sylvella Hew. (40 c), from western Ecuador, closely resembles the smaller *Episcada sylpha* (39 c). The ♂ has in addition to the red-brown subcostal a broad streak at the median of the forewing and also a partly reddish brown distal margin to the hindwing. The half-band at the end of the cell is proximally narrower and beside it is placed only a small white spot at the costal margin. In the ♀♀ the red-brown colour is absent above, only the subcostal of the forewing is slightly red-brown. — In ab. **ornata** Hsch. the forewing has a broad white half-band, which in the ♀ is sometimes continued, though here less distinct, to the distal margin.

29. Genus: **Aeria** Hbn.

Here begins the group of genera in which the lower discocellular of the hindwing in the ♂ is not angled and forms an acute angle with the median. In *Aeria*-♂ the lower discocellular is slightly undulate, the middle somewhat shorter than the long upper one; in the ♀ the lower is angled, the upper is absent, as the upper radial branches off from the subcostal. The ♂♂ of some forms have at the end of the cell of the forewing on the upper surface a larger spot of thickly massed, glossy brown scales. The few known forms are all very nearly allied and recall species of *Scada* by their yellow-black colouring. They mostly occur in northern South America and in Central America, and are not rare in open places in the woods.

A. eurimedia Cr. (= *aegle* Hbn., *indola* Dbl. & Hew.) (40 f). Typical examples of this species occur only in Guiana and on the Lower Amazon. They have a large, half oval yellow subapical spot in the forewing and also broad black oblique band and margins, there being only an oblong yellow spot at the base. — In the form **negricola** Fldr., from the Upper Amazon, the subapical spot is longer and the yellow basal patch is broader and triangular. On the under surface of both forms the margins are variegated with red-brown. — **pacifica** Godm. & Salr. is the form from northern Central America. The black markings are very broad, so that only narrow yellow stripes remain at the base of the forewing and in the disc of the hindwing. The subapical band of the forewing is very large and like the other yellow markings darker than in *eurimedia*. The under surface, as in the latter, is variegated with red-brown. — **agna** Godm. & Salr. (40 f) is the form from southern Central America as well as Colombia and Venezuela. It may be recognised especially by the absence of the red-brown colour on the under surface. The pattern and colouring are otherwise similar to the preceding, with somewhat broader yellow bands at the base of the forewing and on the hindwing. — **palmara** Hsch. is a form from western Ecuador. It differs from *agna* in

sisenna, the narrower yellow subapical band and broader basal triangle on the forewing. ab. **sisenna** Weym. is a form of the preceding in which the yellow subapical band of the forewing is broken up into 2—3 small yellow spots. It occurs together with the principal type in Ecuador.

elara, **A. elara** Hew. is a smaller, delicate species from the Upper Amazon, with proximally sinuous yellow subapical band and narrower distal margin to the hindwing. On the under surface it shows the red-brown colour especially at the hinder angle of the forewing and the inner angle of the hindwing. — **elarina** Oberth., from the Lower Amazon, is somewhat larger, with narrower wings and brighter colouring. The special character of this form is the presence of a black triangle at the end of the cell of the hindwing, extending from the costal margin.

elodina, **A. elodina** Stgr., from Venezuela, is pale yellow and has a narrow black oblique band across the end of the cell of the forewing, the costal and distal margins of the forewing are also black and the costal margin of the hindwing is narrowly so. *elodina* may be recognised especially by the narrow yellowish costal margin of the hindwing beneath.

olena, **A. olena** Weym. (40 g), the only species from Central Brazil, differs from the preceding by the absence of the white marginal dots on the under surface. It is of only small size, and has delicate, blackish colour with narrow yellow subapical band on the forewing and longitudinal band on the hindwing. The yellow basal triangle in the forewing on the contrary is broad.

30. Genus: **Velamysta** Hsch.

Under this name I unite a small group of species which differ from *Hypoleria* in the absence of the oblong scent-spot in the middle of the costal margin in the ♂. Costal and subcostal in this genus separate gradually and only approach one another again behind an indistinct scent-spot which is placed at the extremity of the cell, after which, parting once more, they reach the margin in a curve. The scent-spot is mostly marked by a whitish angular spot on the under surface and on the upperside covered by a hair-pencil arising at the end of the cell. In the ♀ costal and subcostal are coincident to one half, the upper discocellular is absent and the lower is mostly angled, which is not the case in the ♂. There belong here only a few rare, medium-sized forms, which in the markings recall species of *Leucothyris* and *Dismenitis*. They occur apparently only in high-lying mountain-forests of the eastern Andes from Ecuador to Bolivia.

crucifera, **V. crucifera** Hew. (40 f), from Ecuador, is similar to *Dismenitis theudelinda* (41 d) and *V. pardalis*, but somewhat smaller. The forewing is shaded with light brown, with whitish dots, dark borders and a brown, irregular spot at the end of the cell of the forewing. The hindwing has bluish sheen and a peculiar, broad black-brown colouring at the distal margin, in which are placed large whitish distal-marginal spots. The costal margin of the hindwing is blackish to the apex with a wedge-shaped spot at the end of the cell. In the ♂ the colouring is on the whole somewhat weaker than in the figured ♀.

torquatilla, **V. torquatilla** Hew. (40 f, as *peninna*) and **peninna** Hew., both from Bolivia, are very similar, so that I at first regarded them as one species. Only after seeing a specimen of the true *peninna* I discovered my mistake and it seems to me now that the two even belong to different genera. The specimen figured is a ♀ of *torquatilla* (**not** *peninna*); in the ♂ the dark markings are weaker, especially in the disc of the forewing; and on the hindwing the median band is only indicated at the apex. On the under surface all the margins are rust-brown. — In *peninna* the otherwise similar marking is on the whole weaker and lighter brownish. In the ♀ the oblique band of the hindwing is placed nearer to the distal margin.

pardalis, **V. pardalis** Salv. (40 e) is probably also best placed in this genus. The venation appears to vary somewhat, as I possess a ♂ with the lower discocellular of the hindwing angled, much as in *Callithomia*, whilst in other specimens this vein is not angled. Superficially this rather rare species recalls *Dismenitis theudelinda* (41 d), with which it occurs in the highest mountain-forests of the Andes in Ecuador. It may be known by the dark oblique band at the end of the cell of the hindwing and the spots between the end of the cell and the apex of the forewing. In the ♀ the hindwing is of the same brownish colour as the forewing.

pupilla, **V. pupilla** Hew. (40 f), from Bolivia, is smaller, with similar markings and lighter margins, especially the costal margin of the forewing, which is reddish. The half-band at the end of the cell and the spot in the cell of the forewing are narrower. The dark marking in the apex of the hindwing is only very weak in the ♂. The ♀ probably resembles *dispersa*, if this is not indeed the ♀ of *pupilla*. — **dispersa** Weym., from Bolivia, has very similar markings to the ♀ of *torquatilla*. The dark patches at the apex and between the cell and distal margin of the forewing are fainter. — Another similar form, but somewhat larger, is **circilla** Hew., from Bolivia. The wings have a yellowish tint, with similar markings on the forewing to *crucifera*, but with yellow-red costal margin and yellow spot at the end of the cell. The hindwing has in the ♀ a proximally dentate dark distal margin, with 2 white dots at the apex and a half-band at the end of the cell.

anomala, **V. anomala** Stgr., from the Cauca Valley, has almost unmarked wings and recalls *Episcada canilla* (39 c) and *paradoxa*. The ♂♂, however, have the characteristic white spot at the costal margin of the hindwing beneath. The wings have a slightly yellow-green appearance, with no other markings. The costal and inner margins of the forewing are brown, the distal margins only very finely edged with dark.

31. Genus: **Hypoleria** Godm. & Salr.

The ♂♂ may be recognised by the elongate oval scent-spot at the costal margin of the hindwing and by the non-angled lower discocellular, which forms an acute angle with the median, is curved inwards and mostly aborted at the lower radial. In the ♀ costal and subcostal are coincident to the middle, otherwise the venation is as in the ♂.

The forms which belong here have mostly a rounded apex to the forewing and roundish hindwing. In addition to those with colourless wings there are also gay-coloured species, especially a group with red-brown band in the apex of the forewing, such as may be found in *Leucothyris* and also in *Pseudoscada*. Some forms also resemble the latter genus in other respects, so that it is often not easy to differentiate ♀♀ of the two genera.

Of this not very extensive genus also the region of the eastern Andes produces the largest number of species, yet some forms also occur as far as South Brazil and in Central America.

H. vanilia H.-Schäff. (40 g), from Colombia, is very similar to the smaller *Pseudoscada lavinia* (41 b). *vanilia*. The forewing is shaded with dark, with black margins and 2 oblique bands at the end of the cell and before the apex. The interspace is divided by the dark-marked veins into a number of whitish spots. The hindwing is rust-brown, with broad border at the apex; in the ♀ with yellow-brown, proximally dark brown costal margin, in the ♂ transparent at the costal margin. — **libera** Godm. & Salr. is a local form of *libera*, the preceding from Central America (Panama, Costa Rica). It has more strongly marked dark patches and brighter red-brown colour on the hindwing. — **fumosa** Godm. & Salr., from Panama, is a form of the *fumosa*, preceding with darkened apical spots and triangular spot in the cell of the forewing.

H. hyalinus F., from Brazil, is a doubtful form and unknown to me in nature. According to *hyalinus*. BUTLER it is a form similar to *vanilia*, with transparent forewing and black margins, and also a macular band in the apex. Hindwing red-brown with narrow black distal border.

H. fausta Stgr., from the Upper Amazon, is a smaller species with brownish hindwing and base of *fausta*. the forewing. Across the end of the cell of the forewing is placed a broad dark half-band, which is divided at the median veins. In the end of the cell and at the distal margin there are whitish patches.

H. alema Hew., from Colombia, has according to HEWITSON'S figure transparent yellowish wings with *alema*. dark margins and narrow band across the end of the cell of the forewing; before the distal margin of the latter with whitish dots. On the under surface the margins are reddish, except the blackish costal margin of the hindwing.

H. ina Hew., from Ecuador, is a similar species with a row of whitish submarginal dots at the *ina*. distal margin of the forewing and without markings at the end of the cell. The inner margin of the hindwing is broadly reddish yellow-brown. In this the species recalls *Napeogenes apulia* (35 f).

H. ocalea Dbl. & Hew. (41 g), from Venezuela, Trinidad and Colombia, has light yellow-brown wings *ocalca*. with dark margins and an oblique band across the end of the cell of the forewing, which is continued beyond the 3rd median vein. The median of the forewing and the veins of the hindwing are yellow-brown. The macular band of the forewing is yellowish. — The white, longitudinally ribbed eggs are according to GUPPY attached singly about 2 ft. above the ground. The larvae hatched in 5 days. They are transparent, green, with whitish head and take 9 days to feed up.

H. gephira Hew. (41 g), from Colombia and the adjoining parts of Central America, is a similar *gephira*. species with broader margins; with whitish spots in the apex of the forewing and at the distal margin of the hindwing. Moreover the veins in the distal half of both wings are black.

The following forms have a broad yellow-red subapical band in the forewing and hence resemble the similarly marked forms of *Leucothyris* and *Napeogenes*, and also certain Erycinids.

H. chrysodonia Bates, from the Upper Amazon, is almost the same size as **aureliana** Bates (= from *chrysodonia* *aureliana*. *bona* Srka.) (41 a), from the same district. In the former the yellow-red colour is proximally semitransparent. The 2nd and 3rd median veins of the forewing are only narrowly margined with dark. In *aureliana* the yellow-red band is broader and the extremity of the median and also its branches are broadly margined with dark brown, so that between the veins only 2 smaller vitreous spots remain. Moreover, the base of both wings is also shaded with dark. The antennae are black in both species, whilst in **karschi** Hsch., which is otherwise very similar to *chrysodonia* and flies at the Upper Napo in Ecuador, they *karschi*. have a yellow-brown club. In *karschi* the yellow-red subapical band only reaches the 3rd median vein. — Another similar form is **cidonia** Hew., from Colombia. In this the antennae are black and between the *cidonia*. median veins there are 2 larger colourless vitreous patches. The hindwing has a yellowish submarginal band.

H. orolina Hew. (40 g), occurring at the Upper Amazon as far as the foot of the Andes in Peru and *orolina*. Ecuador, is a smaller, delicate species with almost colourless wings and yellow-brown subapical band. — In **oculata** Hsch., from the Upper Napo, which is the same size, there is another rounded vitreous spot be- *oculata*. tween the end of the cell and the band, which is narrower. — A similarly marked form, but larger than *oculata*, from Ucayali, which I call **sedusa** form. nov., has a white patch at the end of the cell of the *sedusa*.

forewing and 3 whitish dots before the distal margin. The vitreous areas of both wings are slightly shaded with brownish.

- oncidia*. **H. oncidia** Bates, from the Upper Amazon, has similar markings to *orolina*; it is somewhat smaller and has whitish dusting in the end of the cell and before the distal margin of the forewing, and also in *tenera*, the disc of the hindwing. — A very nearly allied form is **tenera** Srnka, from Pebas, which has 3 white dots between the median veins of the forewing, whilst only 2 of these are said to be present in *oncidia*. — *quadrona*. In a further form from Yurimaguas, on the Upper Amazon, which I call **quadrona** form. nov., the yellow-red band is only very narrow and between it and the broad band at the end of the cell of the forewing there is another whitish patch.
- cymo*. **H. cymo** Hbn. (= *galita* Hew.) (41 a) has a dark half-band across the end of the cell of the forewing and adjoining it a white patch. The distal margin of the hindwing is red-brown, with dark edges. On the under surface the distal margins together with the costal margin of the hindwing are light red-brown with dark edges. — In the form **indecora** Hsch. (= *sylphis* Kaye), from British Guiana, the red-brown colour at the distal margin of the hindwing is absent. At the distal margin of the forewing there are white dots, and the margins of the under surface are yellow-brown.
- garleppi*. **H. garleppi** Hsch. is similar to the preceding, with narrower white patch at the end of the cell and without the whitish dots at the apex of the forewing.
- famina*. **H. famina** Hsch. (41 a), from Peru, has the wings more strongly dusted with white and an angular smoke-brown spot in the cell of the forewing. On the under surface the dark margins are variegated with yellow-brown. — In **oriana** Hew., from the Upper Amazon, the costal and distal margins of the hindwing are much broader and leave in the disc only a vitreous longitudinal band, just as in *Leucothyris onega*.
- virginia*. **H. virginia** Hew. (40 g), from the Amazons, has smoke-brown wings with broad dark margins and broad apex to the forewing. Across the cell of the latter is placed a wedge-shaped oblique band and towards the apex a broad, segment-shaped, white band.
- xenophis*. As **H. xenophis** spec. nov. I designate an isolated species from the Rio Ucayali, with elongate, yellow-dusted wings, which recalls *Episcada canilla* (39 c). The forewing has before and behind the end of the cell a dark pointed half-band, as well as dark margins. The greater part of the hindwing is dusted with yellow; it has likewise dark margins. On the under surface all the margins are red-brown, dark-edged, without white marginal dots.
- coenina*. **H. coenina** Hew. (40 g) differs considerably from most of the other forms by the pointed apex of the forewing and the absence of marking at the end of the cell. The wings are dusted with grey and have fairly uniform black margins. The latter are black also beneath. — In ab. **adornata** Hsch. the margins are bright red-brown on the underside, especially at the base and the anal angle of the hindwing.
- veronica*. **H. veronica** Weym., from Colombia, is larger than *coenina*; the distal margins are proximally dentate. Across the end of the cell of the forewing there is a black triangle and at the anal angle of the hindwing a rust-coloured oblong spot. The species resembles *Pteronymia thabena* and *tucuna*.
- oreas*. **H. oreas** Weym. (41 a), from southern Brazil, has broad, glossy bluish white wings with dark margins and on the forewing whitish dots at the distal margin. The half-band at the end of the cell is broad, especially in the ♀. — A nearly allied form is **proxima** Weym., likewise from South Brazil. Here the wings are colourless, the margins above grey-brown and beneath yellow-brown. In *oreas* the margins are red-brown beneath.
- mirza*. **H. mirza** Hew. (= *lavinia* Hew. p., *ryphaeno* Oberth.) (41 a), from western Ecuador, has a narrower half-band in the forewing and whitish dots at the end of the cell and the distal margin, of which those before the apex are proximally bounded by a weak oblique band. — **riffarthi** Hsch., from Ecuador, has similar, but stronger markings. But here the forewing is further distinguished by a white half-band between discocellular and apex.
- cassotis*. **H. cassotis** Bates, from Guatemala, and **rhene** Godm. & Salv. (41 a), from Panama, are very similar to each other. In *cassotis* the half-band at the end of the cell of the forewing is proximally forked, in *rhene* pointed. Moreover, the cell of the hindwing is said to be much longer in *rhene*, the lower radial on the contrary very short. — **cajona** Hsch., from south-eastern Peru, is another similar form with broader black apex to the forewing and without reddish subcostal.

32. Genus: **Pseudoscada** Godm. & Salv.

This genus differs from *Hypoleria* in the absence of the oblong scent-spot in the ♂. Costal and subcostal are almost entirely coincident. The separation of the two genera, however, cannot be rigidly carried out, as in some species an oblong raised patch combined with an indistinct costal indicate the transition. On the other hand *Pseudoscada* shows also relationship to *Hymenitis*, so that it is doubtful to which genus some species belong.

To *Pseudoscada* are referred a number of small species, some of which are also externally very similar to forms of *Hypoleria*. The sources of the Amazon and Brazil produce the most species, whilst from Central America only a few species are known from the southern part.

P. lavinia Hew. (= *saturata* Stgr.) (41 b), from eastern Colombia, much resembles *Hypoleria vanilia*, *lavinia*, but is smaller and the shape of the wings is different, as is also the neuration. — An allied form is **troetschi** *troetschi*, Stgr., from Costa Rica. The base of the forewing is colourless and the hindwing has only at the dark distal margin a broad red-yellow stripe. The rest of the hindwing is colourless.

P. florula Hew., from Cayenne, has a similar pattern to the figured local form **exornata** Hsch. (41 b), *florula*, *exornata*, from British Guiana. It lacks, however, the red-brown colour in the distal margin of the hindwing, which distinguishes *exornata*. On the under surface the margins in both forms are yellow-brown. *exornata* resembles *Napeogenes potaronus* (35 f), which likewise flies in British Guiana, and also *Hypoleria cymo* (41 a).

P. egla Hew., from the Upper Napo, and the two following forms are very similar to *Hypoleria on- egla*, *cidia* and its allies, as well as *Napeogenes corena* (36 b). *egla* has a broad yellow-red subapical band in the forewing and at the hinder angle 2 separated, roundish vitreous spots between the median veins. — In **aureola** Bates (41 b) the yellow-red band is still broader, so that at the hinder angle only one larger vitreous *aureola*, spot remains. This form flies on the Upper Amazon. — In **sarepta** Hew., from the Rio Negro, the yellow- *sarepta*, red band is proximally bordered by a broad brown stripe, which extends from the end of the cell beyond the 2. median vein to the hinder angle, as in *Napeogenes corena*.

P. utilla Hew. (= *pusio* Godm. & Salv.) (41 b), from western Colombia and Ecuador, recalls *Hypo- utilla*, *leria mirza* (41 a), but is considerably smaller and the whitish dots in the apex of the forewing are not proximally surrounded with dark.

P. seba Hew., from eastern Ecuador, has broader distal margins and no white dots at the distal margin *seba*, of the forewing, on the other hand a faint white macular oblique band at the end of the cell. — A similar form is **timna** Hew. (41 c), from Venezuela and the eastern Andes from Ecuador to Bolivia. Here the white *timna*, oblique band is stronger and the veins intersecting it are dusted with white. — Another similar form is **arzalía** Hew. (41 b), from Bolivia, with broader black apex, broader half-band at the end of the cell of the *arzalía*, forewing and a broader, arched, white oblique band.

P. adasa Hew. (41 c), from southern Brazil, is larger than the preceding, and has only a whitish spot *adasa*, at the end of the cell and whitish dots at the distal margin of the forewing. — **acilla** Hew. is a similar *acilla*, form, but smaller, with pointed half-band at the end of the cell and narrower distal borders. — **jessica** Hew. *jessica*, is the same size as *adasa*, but has a pointed half-band like *acilla*. It differs from the latter in the neuration of the hindwing, the lower discocellular forming a very acute angle with the median and ending proximally to the middle discocellular, in *acilla* on the contrary distally to it. — A fourth similar form is **erruca** Hew., *erruca*, with the distal margins more strongly dentate at the veins and white half-band beside the end of the cell on the forewing. It is said to be further distinguished from *adasa* by its more elegant form and to have the end of the cell of the forewing placed almost transversely to the length of the wings. — All four forms come from southern Brazil and are not easy to differentiate. They might even belong to different genera, which can only be determined with certainty from the types.

There follows now another group of forms whose ♂♂ are distinguished by the more pointed apex of the forewing.

In **P. fallens** Hsch. (41 c), from Central Brazil, the basal half of both wings is dusted with yellow, *fallens*, especially in the ♀, which on account of the broader distal borders strongly resembles *Pteronymia euritea* (40 d). The half-band at the end of the cell of the forewing is strongly pointed. The base of the hindwing beneath is red-brown, in *euritea* yellow.

P. salonina Hew. (41 b), from Bolivia, has colourless wings with dark brown margins and half-band *salonina*, at the end of the cell of the forewing and also a yellowish oblique band towards the apex. — A very similar form, with somewhat broader margins, flies also in Paraguay. — As **trepotis** *form. nov.* I designate a form *trepotis*, like *salonina* with white instead of yellow oblique band on the forewing. It flies likewise in Bolivia. — **subtilis** Hsch., from eastern Ecuador, is distinguished from *salonina* by yellowish dusting on the wings and *subtilis*, weaker half-band across the end of the cell of the forewing.

P. emyra Hsch., from Central Brazil, is a similar form to *arzalía*. The black apex of the forewing *emyra*, and the triangle at the end of the cell are broader. The 3. median vein remains black in the white oblique band. The distal margin of the hindwing is narrower.

33. Genus: **Dismenitis** Hsch.

The species of this genus were formerly united with those of *Hymenitis*. In the ♂♂ the lower radial of the hindwing is completely developed, hence the cell is closed. In the ♀ the upper radial is partly coincident with the subcostal; the lower radial is distinctly present; the lower discocellular is angled, with short upper arm and recurrent vein.

The genus contains for the most part imposing-looking species, some of them brightly coloured, which inhabit especially the high mountain range of the eastern Andes near the Equator. Some species also fly in the mountains of Central America.

- zavaleta*. **D. zavaleta** Hew. (41 c), from Colombia and Peru, has yellow-dusted wings, a transverse band in the cell of the forewing and broad black distal margin to the hindwing with white dots. The distal half of the antenna is yellowish. — In the form **amaretta** Hsch., from eastern Ecuador, the transverse band through the cell of the forewing is absent, on the other hand the basal third of the cell is dark-shaded. The distal margin of the hindwing is narrower and the white dots are smaller. In the ♀ the base of the hindwing is broadly black. — **matronalis** Weym., from Ecuador and the Upper Amazon, is a form of *zavaleta* in which the white marginal dots are entirely absent above and beneath. — **telesilla** Hew., from western Ecuador, has a similar ♂ to *amaretta*, with weaker yellow dusting and without the dark half-band across the end of the cell of the forewing. The distal margin of the hindwing is broader with very small white dots. The ♀, in which the distal margin of the hindwing is twice as broad, may be recognised especially by a large red-yellow spot at the inner margin of the hindwing.
- gonussa*. **D. gonussa** Hew. (41 c, d, ♂, ♀), from Colombia, is somewhat larger than the preceding species. The ♂ is similarly marked to the ♀ of *zavaleta*. The half-band at the end of the cell of the forewing is broader and the wing has white marginal dots on the upper surface also. In the ♀ the black markings are much broader and the yellow dusting of the ♂ is in this red-brown. The white marginal dots of the hindwing are much larger. — **petersi** Dew., also from Colombia, is a form of the preceding in which the red-brown colour on the forewing and at the apex of the hindwing becomes bright yellow.
- zygia*. **D. zygia** Godm. & Salr. (41 d), from Costa Rica, is similar to *gonussa*. In the ♂ not only the transverse band in the cell but also the whole of the forewing is shaded with dark. The yellowish spots round the end of the cell are larger and joined into a band. The disc of the hindwing is brownish yellow near the veins, especially at the inner margin. In the ♀ the inner margin of the forewing is red-brown in the middle as far as the median, as is also the entire disc of the hindwing. The black distal margin is narrower than in *gonussa* and not proximally dentate at the veins. — **sosunga** Reak. is a form from Honduras with broader yellow oblique band on the forewing and broadly blackish apex to the hindwing. Hence in the ♂ only the basal half of the hindwing is red brown.
- dircenna*. **D. dircenna** Fldr. (41 c) strongly recalls certain species of the genus *Dircenna*, such as *epidero*, etc., but may be recognised by the neuration of the hindwing. The forewing has 2 narrow half-bands across the end of the cell and through the middle of it. The black distal margin of the hindwing is broadened and dentate at the anal angle and in the ♀ there is a roundish black spot at the end of the cell. This interesting species flies in the eastern Andes from Colombia to Bolivia. — **pittheis** Weym., from Colombia, is a similar form, without the bands on the hindwing and with diaphanous forewing. On the under surface the margins are yellow-brown, with a white dot at the apex and the distal margin of the hindwing. — **barretti** Dan. is another similar form from Peru without the bands in the cell of the forewing and at the end of the cell and the distal margin of the hindwing. There are 4 white dots in the black distal margin of the hindwing above.
- duilia*. **D. duilia** Hew. (41 d) is one of the largest and most beautiful species of the whole family. When the sunlight falls on the bluish-white-dusted wings the most magnificent colour effects are produced. On the forewing the veins and margins are edged with dark brown, only beyond the end of the cell at the costal margin there is a yellow-red stripe. The hindwing has a broad dark brown costal margin and a broad red-brown inner margin as far as the 1. median vein. *duilia* flies in the eastern Andes from Colombia to Bolivia and is not rare at certain places. A deceptively similar species is the smaller *Hymenitis alphasiboea* (41 f). Another similar form is **nepos** Weym. (= *lora* Stgr.), from Colombia. The streak at the costal margin of the forewing is only half as long and yellow-brown. The costal margin of the hindwing is much more narrowly bordered with dark. The inner margin is likewise narrower and dark brown, only reddish at the base. The neuration is also somewhat different.
- theudelinda*. **D. theudelinda** Hew. (41 d), from the eastern Andes from Colombia to Peru, is very similar to *Velamysta pardalis* (40 e). But the band-like marking at the apex of both wings is absent, on the other hand a dark spot is placed at the end of the cell of the hindwing. The marking is fairly similar in both sexes.
- hermana*. — **hermana** Hsch., from Ecuador, is a very similar form. In the ♂ the costal and subcostal of the hindwing

are coincident to the end of the cell; only one hair-pencil is present, the upper radial is absent. The dark spots at the end of the cell on both wings are smaller. The white marginal dots of the hindwing are triangular. — **zalmunna** Hew., from Ecuador and Peru, is another similar form with narrower margins, narrower marking across the end of the cell of the forewing and without a spot across that of the hindwing in the ♂.

D. cleomella Hew., from Bolivia, is likewise similar to *theudelinda*, but the yellowish club of the antenna is distinctive. The costal margin of the forewing is not yellow-brown. Both wings have yellow tone. The pattern is somewhat different from that of *theudelinda*. The distal margin of the forewing is more broadly margined with black between the teeth. The white marginal dots of the hindwing are smaller. The spots at the end of the cell on both wings narrower, band-like.

D. crinippa Hew. (41 d), from Bolivia, has brown, dentate distal margins and in addition to the half-band of the forewing a spot in the cell, as well as yellowish dots at the end of the cell and before the distal margins.

A similar, somewhat smaller species, which I call **D. lauta** spec. nov., differs especially in the absence of the band-spot in the cell of the forewing. It is very similar to *Hymenitis umbrosa*, from which it may be distinguished both by the size and the different neuration. In the ♀ the two white dots of *umbrosa* at the apex of the hindwing beneath are wanting.

In **D. cleonica** Hew. (41 e), from eastern Colombia and Ecuador, the markings are similar, without the spot in the cell of the forewing and with yellowish colour in the basal half of the hindwing and a white spot at the end of the cell of the forewing. — **panthyale** Fldr., from Colombia, is similar to the preceding, without the yellowish colour on the hindwing and with red-brown subcostal and median to the forewing.

D. hewitsoni Hsch. (41 e), from eastern Ecuador, has transparent wings with yellow-brown sheen, with fine, darker margins and no other markings. Subcostal and inner margin of the forewing are light brown.

34. Genus: **Hymenitis** Hbn.

In this genus the lower discocellular of the ♂ is not angled and is undeveloped towards the costal margin, hence the cell open. The principal difference from *Dismenitis* is seen in the ♀♀. In these the upper radial of the hindwing is coincident with the subcostal to one-half, in *Hymenitis* it is coincident with the lower radial half-way. Hence the middle discocellular is absent here.

To *Hymenitis* belong mostly medium-sized, plain-looking forms, which resemble certain species of *Leucothyris* and *Pteronymia*, but may be recognised by the non-angled, slightly curved lower discocellular, which closes the cell almost alone. Some larger species recall forms of *Velamysta* and *Dismenitis* in the pattern and colouring. This genus is rather rich in species, of which the south-west of South America produces the largest number, but Central America and Mexico have also some characteristic forms.

H. albinotata Btlr. (41 g), from Colombia, recalls *Velamysta crucifera* (40 f) and *torquatilla* (40 f) by the dark markings of the hindwing; the forewing is similar to that of *Dismenitis gonussa* (41 e, d). The colour is yellowish, at the base of both wings red-brown. Particularly striking are the two white dots in the apex of the forewing. — **kedema** Hew., from Venezuela, is a similar, smaller form with weaker, pale colouring and indistinct band-marking at the distal margin of the hindwing. — **furina** Godm. & Salv. is a form of *albinotata* from Panama with dark base to the cell of the forewing, lighter base to the hindwing and weaker black markings at the distal margin of the hindwing.

H. andromica Hew. (41 f), from Venezuela, Colombia and western Ecuador, and its subspecies are some of the commonest and most widely distributed local forms. In typical *andromica* the colourless wings have a slight smoke-brown tinge and black-brown margins and patches. Beside the pointed half-band of the forewing runs a broad, undulate white oblique band from the costal to the distal margin. In the apex are placed 2 whitish vitreous spots, which in the ♀ are completely enclosed by the broad black apex. — As **dromica** STAUDINGER (i. l.) designated a smaller form from Colombia with narrow margins, weak half-band and narrow white oblique band at the end of the cell of the forewing. — **andania** Hpffr. (= *lyrina* Stgr. i. l.) is a form from eastern Ecuador, Peru and Bolivia with vitreous, black-margined wings and interrupted white oblique band on the forewing. The apex of the forewing is more narrowly black and in the ♀ the hyaline spots are not proximally bordered with black. — **lyra** Salv. is the form from Central America (Guatemala, Costa Rica). It is distinguished from *andania* by having the half-band of uniform breadth and not pointed, and a narrower white macular oblique band on the forewing. The black tooth bordering the subapical hyaline spots at the costal margin is absent.

H. nero Hew. (41 e), from Central America, Costa Rica to Mexico, is similar to the preceding, larger, with broader margins and patches. The subcostal of the forewing and the distal margins are partly red-brown. On the underside of the forewing the 2 white apical dots of *lyra* are absent.

- oto*. **H. oto** Hew. (41 e), from Honduras and Guatemala, has broad black apex to the forewing and a broad half-band at the end of the cell as well as a white oblique band. The subcostal of the forewing and the distal margin of the hindwing are partly red-brown.
- morgane*. **H. morgane** Hbn.-G. (41 e), from Mexico and Honduras, is noteworthy on account of the rust-brown margins. Behind the irregular half-band at the end of the cell of the forewing an indistinct, narrow white macular band runs from the costal to the distal margin. — In **moschion** Godm., from Mexico, the rust-brown apex and the half-band across the end of the cell of the forewing are said to be narrower; the white spots do not form a distinct band; the genitalia of the ♂♂ differ from those of *morgane*.
- annetta*. **H. annetta** Guér., from Mexico and Central America, is smaller than *morgane*, with narrower, dark brown margins and a half-band on the forewing. From the end of the cell to the distal margin of the forewing runs a row of white spots, which are not parallel with the dark half-band, much as in *Pteronymia simplex* (40 b). In addition there are 2 white dots at the apex and one at the hinder angle.
- nerina*. **H. nerina** Hsch., from Colombia, is of the same size as *andromica* and has similar markings to *nero* (41 e). The white oblique band of the forewing is broken up into spots. The margins are brown-grey above and light brown beneath, with 2 white dots in the apex of the forewing and one in that of the hindwing.
- polissena*. **H. polissena** Hew., from western Ecuador, closely resembles a form from Costa Rica which I call **umbrana** form. nov. (41 f). Both forms have diaphanous wings with narrow black margins and pointed half-band at the end of the cell of the forewing, and also white dots at the end of the cell and the distal margin of the forewing. *umbrana* has further white dots at the apex of both wings, *polissena* on the contrary only 2 white dots in the red-brown apex of the forewing beneath. In *umbrana* the abdomen beneath is whitish, in *polissena* yellowish. In the ♀♀ the margins and half-bands and also the white spots are broader.
- diaphanus*. **H. diaphanus** Drury (= *unzerina* Hbst.), from the Antilles (Jamaica), which is also said to occur in Texas, is a similar species with narrow distal margin to the forewing and fine distal border to the hindwing. The half-band at the end of the cell of the forewing is of uniform breadth.
- cubana*. **H. cubana** H.-Schäff., from Cuba, has similar markings to *oto*, but very narrow wings and narrower margins. The half-band of the forewing is constricted in the middle and forked at the median. The white oblique band is narrower than in *oto*.
- alphesiboea*. **H. alphesiboea** Hew. (41 f), from eastern Ecuador, is a copy on a small scale of *Dismenitis duilia* (41 d) and apart from the size can only be recognised with certainty by the different venuration. In the ♀ the upper radial of the hindwing is coincident with the lower to one-half, in *duilia* with the subcostal.
- ortygia*. **H. ortygia** Weym. (41 f), likewise from the eastern slopes of the Andes in Ecuador, stands in the same relation to *Dismenitis cleonica* (41 e). In the figure of the ♂ the white dots at the end of the cell and the distal margin of the forewing stand out too little; in the ♀ they are much stronger.
- enigma*. **H. enigma** Hsch. (41 f), from Bolivia, has yellow-brown costal margin of the forewing and dark brown, dentate distal margins, and also yellowish patches at the end of the cell of the forewing and before the distal margins. On the under surface all the margins are ochre-coloured. — A similar form is **umbrosa** Hsch., from the high mountains of the eastern chain of the Andes in Ecuador. In it the margins are narrower, the yellow patches more indistinct, and in the forewing only the subcostal is yellow-brown. In the ♂ the end of the cell of the forewing has no marking. — **esula** Hew., from Colombia, is similar to the preceding; the margins are still narrower, the yellow patches are absent, on the other hand the hindwing is yellowish at the inner angle. Moreover in the ♀ also the end of the cell of the forewing is without marking. — **depauperata** Bdv., from Guatemala, which is unknown to me in nature, is probably a form similar to *enigma*. It is said also to resemble *zalmunna* and to be distinguished from it by the narrower distal margin of the hindwing and the absence of the white spots.
- sappho*. A species from Bolivia which I received as **H. sappho** (Bang.-H. i. l.), of the same size as the preceding, has colourless wings with black-brown margins, of which the distal ones are dentate at the veins. Beside the irregular half-band at the end of the cell of the forewing is placed at the costal margin a white spot, and at the distal margin of both wings there are small whitish patches. Beneath the margins are deep red-brown, at the base of the hindwing yellow-brown.
- gardneri*. **H. gardneri** Weeks, from Bolivia, is a similar form to *pittheis*, without the band in the cell of the forewing. The costal margin of the forewing is red-brown to the end of the cell. At the end of the cell of the forewing and before the distal margins are placed white patches.
- libethris*. **H. libethris** Fldr. (41 f), from Colombia to Peru, and a number of similar forms are distinguished by a bright yellow oblique band in the forewing. *libethris* differs from the very similar **dercetis** Dbl. & Hew., from Venezuela, Colombia and Ecuador, in the more elongated forewing and the shorter inner margin of the hindwing. Moreover the base of the hindwing beneath is yellow. — **ochretis** Hsch., from Colombia to Bolivia, is of the same size and shape as *dercetis*. The oblique band of the forewing is broken up into 2 yellow-brown spots. In the apex of each wing there are 2—3 further yellowish patches. The base of the hindwing beneath is yellow, on the other hand the white dots in the apex of the forewing are absent.

H. lydia Weym., from Ecuador, has a broad, yellow-brown costal margin to the forewing, in which *lydia*, it recalls *Pteronymia apuleia* (40 a) and *Hymenitis enigma* (41 f). The pattern is as in *ochretis*, with smaller, indistinct, yellowish patches.

H. quinta Stgr., from the Cauca Valley in Colombia, is one of the Ithomiids which are entirely without markings on the wings and recalls the very similar *Episcada paradoxa*, with which it also agrees in size, and also *Velamysta anomala*, *Napeogenes hypsaea*, *Ithomia dimidiata* and other forms with unmarked, colourless or yellowish wings. *quinta* is distinguishable from the similar species of other genera by the large, non-angled lower discocellular of the hindwing, which almost alone closes the cell.

35. Genus: **Heterosais** Godm. & Salv.

In this last genus of the Ithomiids the cell of the hindwing in the ♂♂ is open, the middle discocellular and upper radial being absent. The subcostal is strongly developed and curved in the middle. The lower discocellular is directed proximad and forms with the lower radial an acute angle, from the point of which a vein runs into the open cell. In the ♀ the cell is closed, as the lower discocellular is angled and reaches to the upper. Middle discocellular and upper radial are absent here also.

The species of this genus are not numerous. They occur mostly in the north-west of South America and the adjoining districts of Central America. They are mostly inconspicuous forms of medium size, which are found with the similar species of other genera in the undergrowth of the primeval forests.

H. nephele Bates, from the Upper Amazon, and **gedera** Hew. (41 g), from eastern Ecuador and Colombia, are two very similar forms. Both have vitreous wings with bluish sheen and black-brown margins and half-band on the forewing in addition to a white spot at the end of the cell and 2 whitish patches in the apex of the forewing and on its underside 2 more white dots in the distal margin; in the distal margin of the hindwing a row of dark edged white dots. — **edessa** Hew. (41 g) is a similar form from southern Brazil with smaller white spot at the end of the cell of the forewing, yellow-brown margins on the under surface and light base to the hindwing. *nephele.*
gedera.

H. pallidula Hsch., from western Ecuador, has yellowish wings with yellow-brown subcostal and a broad stripe on the median of the forewing. The other margins are dark brown, only the distal margin of the hindwing is partly variegated with yellow-brown. At the end of the cell of the forewing and the distal margins there are yellowish dots. In the ♀ only the subcostal of the forewing is yellow-brown, the other margins are brown. *pallidula.*

H. giulia Hew. (41 g), from Colombia and Venezuela, has a similar ♂ to *pallidula*, with broad yellow-brown subcostal vein and stronger yellowish dots. The ♀ is quite similar, but more brightly marked, with broader margins, yellow oblique band on the forewing and large yellowish dots at the distal margin. *giulia.*

H. cadra Godm. & Salv., from Panama, is said to be similar to *nephele* and *giulia*. The wings are colourless. The dark half-band of the forewing is proximally broader, the band beside it is white, the inner margin yellow-brown. *cadra.*

Addenda.

Napeogenes domiduca Hew. very closely approaches some *Leucothyris*, such as *Leuc. cyrene*; further details are given under the latter, p. 148; from Bolivia.

Alphabetical List

with reference to the original description of the forms of the American Danaidae.

* signifies that the form is also figured at the place cited.

4. Family: **Satyridae.**

This family, which is very rich both in genera and species, is well distinguished by several characters not only in the perfect insect but also as larva and pupa, so that Satyrids are easy to recognise in all stages.

One of the chief characteristics of the butterflies consists in the basally swollen veins of the forewing. In most cases it is only the costal vein which shows this bladder-like thickening, in many cases the median likewise has it, but in some genera also the submedian, e. g. in *Oressinoma*, *Coenonympha*, and to a less extent in *Pierella*. The first three genera *Callitaera*, *Haetera* and *Pierella* have the submedian of the forewing, apart from the above-mentioned bladder-like thickening, also basally forked and form in this the transition to the *Ithomias*, which is also indicated by the partly thin, hair-like scaling and the transparency of the wings. Of the subcostal veins 2 mostly arise before and the rest behind the end of the cell of the forewing, but several genera differ in that the 2. subcostal vein only arises at the end of the cell or behind it. The middle cell of both wings in all the Satyrids is closed, the lower discocellular vein of the hindwing moreover in almost all the genera runs into the curve of the upper median; only in two of the first genera, in *Haetera* and *Pierella*, is this not the case. In *Haetera* the lower discocellular and the median meet at the origin of the middle median vein, in the genus *Pierella* on the other hand between the origin of the middle and that of the lower median.

The shape of the wings is rather variable. Sometimes both wings are rounded, sometimes only the forewing, whilst the margin of the hindwing is undulate or dentate. Often the forewing also shows angles at one of the radials, sometimes the apex of this wing is sickle-shaped or the costal margin itself is produced into a sharp point. Moreover sharper angles and points occur at the three median veins and at the submedian of the hindwing or the lower median vein is prolonged into a rather long tail (*Corades* and *Bia*).

The inner margin of the forewing in the greater number of species is straight or deviates but little from the rectilinear, only in the ♂♂ of the genus *Antirrhoea* and in one species of *Caerois* is it so much outcurved that the anterior part of the hindwing is covered by it. In this expansion is placed on the under surface between median and submedian the so-called scent-organ, consisting of a row of closely approximated, stiff hairs, which often form a semicircle or a wedge-shaped, pointed ellipse, the curly tips of the hairs bending over towards one another. In addition to the genus *Antirrhoea* the scent-organ is only found in the ♂♂ of the *Caerois*-species. In one species of this latter genus, however, it is placed close to the inner angle on the underside of the forewing, so that it is not covered by the hindwing. Tufts of hair are also found in the genus *Bia* on the upperside of the hindwing, smaller hair-pencils in some *Euptychia*. Perhaps these may likewise be regarded as scent-organs, as they only occur in the ♂♂.

The greater proportion of the species of Satyrids are above uniform dark brown, so that the markings are confined to the under surface. Here belong most species of the genera *Taygetis*, *Euptychia*, *Lymanopoda*, *Pedaliodes* and *Pronophila*. But all these genera show at the same time a number of species which are brightly coloured also on the upper surface and have striking and beautiful markings. On the underside the ocellated markings are represented in a variety of ways. Several species have also beneath larger or smaller silver spots or silver stripes and dots. Some Chilian species have the wings entirely silver-coloured above.

The antennae of the Satyrids are mostly thin and delicate, at the same time rather short, not reaching half the length of the forewing. The shaft widens very gradually into the little-thickened club, only a few genera have a short, broad club. The palpi are usually densely and strongly haired, sometimes the eyes are also hairy, the forelegs in both sexes aborted.

The eggs of the American Satyrids, as far as they are known, have a rather spherical or hemispherical form, with the sides ribbed or regularly divided by raised transverse ridges.

The larvae are spindle-shaped, thicker in the middle, narrowed towards each end, but the head in several species is thicker than the anterior segments, also sometimes with 2 short, obtuse horns above, in others also at the sides provided with conical protuberances on which are placed short bristly hairs. The smooth or finely granulated, spineless body terminates at the posterior end in 2 points, which are mostly straight, but sometimes also curved upwards. The colour is mostly green, but there occur also longitudinal stripes of various colours. They live on grasses, reeds, species of bamboo, sugar-cane and palms, remain hidden by day and come out at dusk to feed.

The pupae are comparatively short and thick, without strikingly projecting angles. They are either attached at the tail-end or lie free on the earth or are hidden under stones.

Many of the tropical Satyrids are dusk-butterflies, i. e. they remain at rest all day and fly about near the ground in the early morning and the dusk of evening with unsteady, sometimes jumpy flight in woods or thickets. Here belong the dark-coloured species of *Taygetis* and *Euptychia*. All day long we find single *Taygetis* in the dense timber-forests, resting with closed wings on the ground, where they can

scarcely be distinguished from the dried foliage and are not noticed until they fly up. Herr HAENSCH, who has been kind enough to give me these notes on the habits of the Satyrids, for which I am much indebted to him, has observed that specimens when pursued lay down flat on the dry leaves on the ground and could then only be found by startling them up. The transparent species of *Callitaera* and *Haetera*, as well as the nearly allied *Pierella*, are always found in the shady timber-forests, mostly singly near the ground, and prefer the narrow foot-paths. When one comes near them, they rise at a distance of a few paces and fly along the path close to the ground, soon settling again, but only again to fly off on being pursued. In this way the weak-flighted insects may often be followed for quite a distance, until, leaving the path, they are lost in the wood. The least shy of light are the genera *Oxeoschistus*, *Lasiophila*, *Pedaliodes* and *Corades*, thus in general the most brightly coloured forms. These are frequently mountain species, occurring at elevations of over 2000 m. They are met with gregariously fluttering backwards and forwards on the road or feeding on the ground at the excrement of cattle and other foul substances, but always near to thickets, where they take refuge in danger. The species of *Corades* are not easy to recognize in a bush, as they rest on twigs with the wings closed after the manner of *Kallima*.

The Satyrids are distributed in America from the extreme south (Tierra del Fuego) to the arctic regions of the far north. Tierra del Fuego produces an *Erebia* and a *Cosmosatyrus*, whilst in the northern region occur, besides representatives of the genus *Erebia*, also of the genera *Coenonympha*, *Satyrodes* and *Oeneis*. In the high mountains of South America the Satyrids ascend to the snow-line and hence we find in Colombia, Ecuador, Peru and Bolivia even at elevations of over 4000 m. single representatives of the genera *Pedaliodes*, *Lymanopoda*, *Pseudomaniola* and *Cosmosatyrus*. Among these inhabitants of the mountains there are some species which are very local and only have a limited range of distribution. Hence on closer investigation of such remote, hitherto little explored districts new forms are still found.

1. Genus: **Callitaera** Btlr.

Delicate butterflies with thin body, transparent, thinly scaled, rounded wings, small, sparsely haired palpi, thin antennae, only a little thickened apically. The costal vein of the forewing is strongly swollen at the base, the median on the other hand but little, the submedian is basally forked. Two subcostal veins arise before the end of the cell, the upper discocellular is absent. In the hindwing in this and the 2 following genera the costal and subcostal veins arise from the base near together. The lower discocellular runs into the origin of the upper median vein. — The species are distributed over tropical South and Central America. They fly slowly and low in the early morning hours in dark timber-forests. Several of the species are very similar and all are of nearly the same size.

menander. **C. menander** Drury (= andromeda F. (pt.)) (42 a). Forewing with the margins narrowly dusted with brownish and 2 fine brown transverse lines, one running through the middle of the cell, the other across the discocellulars, but both extending from the costal to the inner margin. On the hindwing near the distal margin and apex a round black eye surrounded by a yellow and a brown ring and with a white pupil, which, however, is not placed in the middle but at the distal margin of the black part. The inner transverse line of the forewing is continued indistinctly on the hindwing, the outer one is somewhat broader and more band-like; forms on the anterior median vein a distally directed, acute angle and then extends to the hindmargin. The posterior part of the distal margin is narrowly edged with brownish and the space between it and the above-mentioned band is light rose-red, especially in the ♂. — Central America. Colombia.

pireta. **C. pireta** Cr. (42 a) is very similar to the preceding species and differs from it chiefly in having in the posterior half of the hindwing near the brown distal-marginal stripe a further brown submarginal stripe, which is not present in *menander*. All these stripes, marginal, submarginal and outer median, are covered, as it were, by the light rose-red colour. — From the Upper Amazon, Ecuador.

aurora. **C. aurora** Fldr. is similar to the preceding species, but according to the original description is not marked with purple but pale lilac in the posterior part of the hindwing and is dusted with ochre-yellow, and also has the ocelli on the wings elongated. The figure of *aurora* in STAUDINGER's exotic work pl. 77 does not agree with this. This figure I regard as belonging rather to the following *aurorina*; *aurora* Fldr. *aurorina.* occurs in Colombia and North Brazil. — **aurorina** form. nov. (= *aurora* Stgr. nec Fldr.) (42 a). I give this name to the form similar to *pireta* Cr., in which the light rose- or purple-red colour of the hindwing extends from the distal margin into the cell and nearly reaches the base of the wing. From Colombia and the Upper Amazon.

pellucida. **C. pellucida** Btlr. (42 b) is a species similar to *menander* Drury, in which the rose-red dusting is entirely absent. The brown marginal band and the similarly coloured submarginal band of the hindwing

are connected by short brown stripes lying along the veins. There are 2 brown dots before the margin near the eye-spot. — Cayenne.

C. philis Cr. (= *cissa* Hbn.) (42 b). Very similar to the preceding species, but has the brown *philis*. marginal and submarginal stripes of the hindwing somewhat narrower and the median area before these stripes sprinkled over with violet-blue dust, which, however, is laid on so thinly that the wing remains transparent, only in certain positions showing a very distinct blue reflection. Surinam. — **harpalyce** Btlr. *harpalyce* is probably only a local form of the preceding, which has the blue reflection along the median veins specially distinct, and which in addition to the eye at the anterior part of the distal margin has also a small eye with a yellow ring between the middle and lower median veins. From the Upper Amazon.

C. esmeralda Dbl. (The older name *andromeda* F. cannot be employed for this species, because *esmeralda*. FABRICIUS has mixed up several species together under this name.) Similar to the preceding species, but the blue reflection in the central area of the hindwing is wanting. Instead of this the posterior part of the distal margin is bluish violet, and at each side of the lower median vein is placed in this border a red-yellow ring with white centre. The eye in the anterior part of the distal margin is as in the other species. Between this and the two posterior ocelli there are 2 round white spots. Pará. — As **bandusia** *bandusia*. Stgr. an *esmeralda*-form has been described in which instead of the two anal ocelli of the hindwing there are two reddish white spots placed in a large cyaneous spot. From the Rio Maues, a tributary of the Lower Amazon.

C. pyropina Godm. & Salv. (42 b). Forewing without markings. Hindwing at the anal angle with *pyropina*. broad, brownish violet distal margin which extends to the lower radial. In this are placed 3 rose-red spots and close to the margin a narrow rose-red stripe. The ocellus in the anterior part of the distal margin is as in the allied species, behind this is a white dot. — From Bolivia and East Peru.

C. polita Hew. (42 b). The only species of the genus which shows on the hindwing no red or blue *polita*. colour. The wings are shorter and broader than in the other species. Costal and distal margins of the forewing are narrowly brown, 2 half and 2 entire narrow brown transverse stripes traverse the forewing, whilst the hindwing has only a marginal and a submarginal band, of which the latter is strongly angled. The ocellus in the anterior part of the distal margin as in the other species. — From Nicaragua, Chiriqui in Panama, Costa Rica, Colombia, rare.

2. Genus: **Haetera** F.

The butterflies are on an average somewhat larger than those of the genus *Callitaera*, but the wings are equally delicate and transparent, and the submedian of the forewing is forked at the base. But the costal vein of the forewing is less strongly inflated. The principal difference, however, consists in the position of the lower discocellular of the hindwing. This vein ends at the origin of the middle median vein. The 3 discocellulars are placed vertically and form almost a straight line, the apex of the cell being acute.

H. piera L. (♀ = *anacardii* F. nec L.) (42 c). Forewing diaphanous, without markings, only with *piera* narrow brownish costal and distal margins. Hindwing in and behind the middle with fine ochre-yellow dusting, with a fine brownish transverse stripe, which is strongly angled in the middle and whose posterior part in the ♀ is darker and more distinct, with brownish distal margin, which forms in the middle a somewhat obtuse angle. Before the distal margin anteriorly a larger and posteriorly a smaller black ocellus, the former with obliquely placed, the latter with centrally placed white pupil. Both ocelli have ochre-yellow iris and brown ring; between the ocelli 2 white dots. Common in Guiana and on the whole of the Amazon, extending to the south of Brazil. In the forests of the Cordilleras of Colombia common at elevations of 1200—2500 m. Flight very slow. The egg is spherical, somewhat flattened at the base, smooth, shiny white. — **diaphana** Luc. (= *hymenaea* Fldr.) is a form of *piera*, in which the ochre-yellow *diaphana*. dusting on the hindwing is absent and the brown markings are more distinctly prominent. Bahia. — **negra** Fldr. is another, larger, form of *piera*, in which the brown submarginal stripe in the ♂ is effaced *negra*. and the marginal stripe placed further from the margin. In the ♀ both stripes are narrower and the proximal one is more curved than in the type form. Rio Negro. — **unocellata** form. nov. (42 c), a hitherto *unocellata*. undescribed local form of *piera*, has on the hindwing only the smaller ocellus before the anal angle. The other larger eye-spot at the apex is absent or only indicated by a black dot. The brownish submarginal band is only distinct in the posterior half of the wing and the space between it and the brownish distal margin is dusted with ochre-yellow at the anal angle. On the under surface the iris of the eye-spot is not red-yellow, but sulphur-yellow and twice as broad, the black centre on the contrary much smaller than above. Bolivia.

maclean-
nanian. **H. macleannanian** Bates (= *diaphana* Btlr. & Druce nec Luc.) (42 c), a similar, somewhat larger species, with the wing-expanse 72—80 mm., which is distinguished by having the posterior half of the hindwing in the ♀ rose-red between distal margin and submarginal stripe. In the ♂ this rose-red colouring is only present in the obtuse angle in the middle of the distal margin. The brown submarginal stripe is mostly broader and more distinct than in *piera*, the eye-spots vary in size, sometimes in the ♀ attaining a diameter of 5 mm. The ochre-yellow dusting in the diaphanous part of the hindwing is absent. — Panama and Costa Rica.

hypaesia. **H. hypaesia** Hew. (42 c) is an easily recognized species, in which the broad dark brown submarginal band of the hindwing is united with the like-coloured distal margin, so that a marginal band of 4—7 mm. in breadth is formed, in which is placed in each cell a hyaline spot. On the forewing a narrow stripe of dark brown dusting runs from the discocellular to the inner margin. Above the eye-spots of the hindwing are not distinguishable, beneath on the contrary distinct, one between the 2 radials, the other close beside the middle median vein. Both are black with brownish yellow ring and white pupil. In many specimens the submarginal band is traversed by a row of brownish yellow lunules. — Common in Colombia, Ecuador, Peru and Bolivia at elevations of 1000—2200 m.

3. Genus: **Pierella** Westw.

The shape of the forewing is similar as in the preceding genera, but that of the hindwing different. The distal margin of this wing is in most species undulate, in some it is obtusely angled at the upper median vein, in *dracontis* it is produced into a point. Although the wings are more densely scaled than in *Callitaera* and *Haetera*, yet the scaling is not nearly so dense as in the following genera. The wings are therefore in all the *Pierella*-species still to a certain extent semitransparent although not altogether diaphanous. The principal distinctive character of the genus is here also found in the position of the lower discocellular of the hindwing. This reaches the median between the origin of the middle and that of the lower median vein, thus between M_2 and M_1 . The costal vein and the subcostal of the hindwing arise separately at the base. The submedian of the forewing is furcate at the base. The ♂♂ have on the upperside of the hindwing in the middle of the inner margin a small oval spot, measuring 2—2½ mm., which is bare or covered with more deeply placed scales. In most species this spot is light coloured, in some with a dark central dot, but in *astyoche* it is dark brown, so that it is here easily overlooked. Only in *hortona* is it large, 10 mm. long and 3 broad, and of a light ochre-yellow colour. The size of the species varies between 55 and 75 mm. wing-expanse. The range of distribution extends over the whole of tropical America, some species reach South Brazil in the south and Mexico in the north.

a) With light, dark-bordered transverse band on the under surface of both wings.

nereis. **P. nereis** Drury (42 d). ♂ 62 mm., ♀ up to 72 mm. wing-expanse. Across the grey-brown, semi-transparent wings runs a straight, dull white, brown-bordered band, which in the middle of the hindwing is widened into a large, pure white spot. The distal half of the hindwing is red-yellow with 2 black, white-centred ocelli and 3 white spots. Distal margin darker brown. The ♀ has 1—3 white dots before the apex of the forewing. On the under surface the ground-colour is lighter, the red-yellow is clouded with grey, the white band is continued in a straight line to the inner margin of the hindwing, the brown distal margin is wanting, the eye-spots are only quite small and in the basal area of each wing there is a brown, shorter or longer line. — South Brazil, Rio de Janeiro. Common.

helvina. **P. helvina** Hew. (42 d) approaches the preceding species in the scheme of markings, though not in the colouring. Ground-colour dark brown, light band of the forewing dusted with brownish, the brown bordering broader. In the cell there are 2 brown transverse lines, of which the proximal one is continued to the inner margin, a third short line is placed on the discocellulars, before the apex a round black spot in a light circle with 2 white dots below it and one above. The basal area is brown to beyond one-third the length of the wing, rather straight-margined distally. Then follows a large, triangular, carmine-red area which extends from the costal margin nearly to the inner margin and also near to the distal margin. The latter is black-brown, at the apex with a black-eye-spot with white pupil, a white dot above it at the costal margin and a similar dot below it in the red area. On the under surface the forewing is as above, only lighter. On the likewise lighter hindwing in the basal area three straight, brown, parallel lines run from the costal to the inner margin. Immediately behind the third line follows a reddish grey band, likewise traversing the whole wing, which in the middle is almost twice as broad as at the costal and hind-margins and is bordered at the distal side by a fourth brown line. Distal margin brown, the eye-spot smaller than above and with ochre-yellow ring, one white dot before and two behind the eye. — Muzo, Colombia.

P. incanescens Godm. & Salv. (42 d) only differs from *helvina* in having the proximal border of the red area of the hindwing 2—3 mm. behind the end of the cell, whilst in *helvina* it runs right across the tip of the cell. The red colouring is placed more distally and posteriorly and encloses two white dots; the brown distal margin is narrower. Distributed in Central America: Chontales in Nicaragua; Irazu and Santa Clara Valley in Costa Rica; Chiriqui, Chepo and Bugaba in Panama. Common at the last-named locality. — **ocreata** Godm. & Salv. is another form, in which the red area of the hindwing is much reduced. The anterior part of it is replaced as far as the median by a large, white, elongate-quadrate spot and the white dot below the black eye-spot is somewhat larger. The brown distal margin is as broad as in *helvina*. This form has a restricted range in Panama, having been found at Calobre and Lion Hill. It is still very rare in collections. — In **hymettia** Stgr. (42 d), a further form similar to *helvina*, the red area of the hindwing is still more reduced, being at a distance from the inner margin and broken up. In the figured ♂ it consists of 3 parts, a spot in the middle of the wing of 12 mm. in length and 6 mm. in breadth, a small round spot in cellule 4 and a red dot below it in cellule 3. In the ♀ all the 3 parts are united into a larger spot. At the middle of the costal margin there is a white spot, which, however, is only half as large as in *ocreata*, only extending to vein 6. The ground-colour of this form is above and beneath dark brown, almost black-brown. From the Rio Dagua and Rio San Juan in West Colombia. Flies in August.

P. astyoche Erichs. (= *larymna* Dbl.) (42 e). Ground-colour brown, 2 parallel, straight, dark brown transverse lines run behind the middle across both wings from the costal to the inner margin. They enclose no lighter band above. This is only present on the under surface, the space between the lines being here filled with whitish grey. Forewing with 2 further dark brown lines in the cell and a third on the discocellular, the hindwing with a similar line in the cell. Two black ocelli with white pupil and yellow iris in cellules 5 and 6 near the distal margin of the hindwing. Somewhat further removed from the distal margin in cellules 2, 3 and 4 three small round white spots with obsolescent dark bordering. The same markings are present on the under surface, only the ground-colour is somewhat lighter. From Guiana and the Amazon. — **lucia** Weym. (Stett. Ztg. 1885, p. 285) (= *astyoche* var. *albomaculata* Stgr.: Exot. Tagf. p. 219, pl. 77, 1887) (42 e) is a form of *astyoche* in which instead of the 2 lower small white spots of the hindwing there is a large white spot close to the distal margin, otherwise it is quite similar to *astyoche*. From Pebas on the Upper Amazon.

P. lena L. (42 e). The forewing on both surfaces resembles *astyoche*, but the hindwing shows in the distal half 4 rows of blue spots mostly with white centres, of which the row next to the distal margin is somewhat obsolescent. Between the 2nd and 3rd rows near the costal margin 2 black eye-spots with white pupils. In the ♀ the basal half of the hindwing is shot with blue. Also the underside of the hindwing is similar to that of *astyoche*, except that the eye-spots are larger and removed more proximad and the proximal part of the distal margin is dark brown. Surinam, Guiana, Amazon, north-eastern part of Rio de Janeiro. — **brasiliensis** Fldr. is an unimportant local form of *lena*, in which the ground-colour of the hindwing is more blue-grey and the bluish white spots are replaced by dirty white ones. From the Rio Negro and the Amazon. — **glaucolena** Stgr. i. l. (42 e) is a local form in which the blue spots of the hindwing are somewhat larger and have no white central dots. Only the spots placed next to the costal margin are somewhat white at the sides. From Mapiri. — **amalia** Weym. (Stett. Zg. 1885, p. 285) (= *leucospila* Stgr.: Exot. p. 220, 1887) (42 e) is a form which HEWITSON figures in the 2nd volume of his Exot. Butterflies as a variety of this species. The bluish white spots of the first and second rows are united in the posterior part of the hindwing into a large white spot, in the anterior part of the wing these 2 rows of spots are absent. The 4th row close to the distal margin consists of round pure white spots, instead of the elongate bluish white ones of typical *lena*. Moreover on the upper surface of the forewing there is a distinct white band in the female. From Pebas on the Upper Amazon.

P. dracontis Hbn. (? = *hyalinus* Gmel.) (43 a) is very similar to *lena* in the scheme of markings, but the shape of the hindwing is different. The distal margin is produced into a strongly projecting angle at the upper median vein. Hence this species forms a transition to the genus *Antirrhaca*. The 3 rows of blue spots on the hindwing are more brightly coloured than in *lena*, the 4th row at the distal margin is absent. From Surinam and the Amazon. — **extincta** Stgr. i. l. A form in which the greater part of the light band on the underside of the forewing is wanting, only the part from the inner margin to the lower median vein being present. On the hindwing the half-band of *dracontis* is divided into 2 parts and the posterior ocellus is extremely small. From Manicoré.

b) Without light band, but with three straight, almost parallel, dark lines on the under surface of both wings.

P. luna F. (= *pallida* Godm. & Salv.) (43 a). Both wings grey-brown, the hindwing somewhat darker in the posterior half, both with 3 fine, brown, almost straight transverse lines, of which the one

- placed next to the base on the hindwing is rather indistinct. At the apex of the hindwing two round black spots, of which the anterior one has a white pupil towards one side, but the other is blind and smaller. On the lighter under surface with fine brown striae the transverse lines are more distinct than above, between the 2nd and 3rd on the forewing there is a fourth, which only extends to the upper median vein. The ocellus of the hindwing is smaller, the black spot is absent. In the marginal area there are 4 white dots on each wing. In the ♂♂ above seen in a certain light there is a light green reflection, in the ♀ the marginal area is darker. Nicaragua, Costa Rica, Panama, Colombia, Guiana. — **heracles** Bdr. (= *rubecula* Godm. & Salv.). A northern form with the same green reflection on the forewing in the ♂, but distinguished by the reddish brown colour of the costal area on the hindwing above. This colour is gradually merged at its edges into the dark brown ground-colour. The dark brown distal margin is 5—6 mm. in breadth. The 2 black ocelli at the apex are placed at the boundary of the two colours and have often white pupils. From Mexico and Guatemala. — **lesbia** Stgr. (43 a) I regard as a southern form of *luna*, which approaches *heracles*. The median patch of the hindwing, however, is more reddish yellow and more distal than the reddish brown patch of *heracles*. The dark brown distal margin is only 1—1½ mm. in breadth and rather sharply defined. Of the 2 round black spots at the apex only the upper one has a white pupil. Under surface as in *luna* and *heracles*. From Bucay in Ecuador and the Rio San Juan in West Colombia.
- rhea**. **P. rhea** F. (43 a) approaches *luna*, having the same markings and the green reflection on the forewing, but the ground-colour is more yellowish brown, the hindwing somewhat darker than the forewing. The former with a row of 5 black ocelli with white pupils, of which the 3 posterior ones are somewhat smaller and the last is often very indistinct. On the under surface the brown lines are as in *luna*, but the eye-spot at the apex of the hindwing is absent, on the other hand the row of dots (2 or 3 on the forewing, 5 on the hindwing) is very distinct. From the Amazon; Rio de Janeiro.
- lamia**. **P. lamia** Sulz. (= *dyndimene* Cr.) (43 a) is similar to *rhea*, the green reflection is likewise present in the ♂ on the forewing, but the hindwing has a steel-blue gloss, which is absent in *rhea*; the 5 black eye-spots are all equally large and distinct, the white dots in them somewhat stronger. From Cayenne, Surinam, Colombia.
- chalybaea**. **P. chalybaea** Godm. was described as similar to *lamia*, but differing from it in that more than the basal half of the hindwing in both sexes is shot with steel-blue, the black rings round the white dots are almost or entirely absent, the distal margin of the hindwing is very broadly darkened and the 2 central lines are indistinct. From Chapada in Brazil.
- hyceta**. **P. hyceta** Hew. (43 b). A beautiful species. The forewing is similar to that of the preceding species in colouring and markings, and also shows the green reflection on the ♂♂ in certain lights, but the hindwing has reddish ochre-yellow ground-colour, only the base and costal margin agreeing with the forewing. Of the 3 brown lines on both wings the middle one on the hindwing forms roughly the indistinct boundary of the two colours. Four, occasionally five, round black spots form a submarginal row, only the anterior one has a white pupil, the 2nd is the largest. Between the 2nd and 3rd is sometimes inserted a fifth spot (as in the ♀-example figured). At the distal margin of the hindwing are placed brown triangles. On the under surface the ground-colour of both wings is yellowish grey, finely mottled with brown, the straight brown lines stand out distinctly, the black spots are much smaller than above, and have here in the ♀♀ white pupils, sometimes also in the ♂♂. From the Upper Amazon, Cuzco in Peru (3000 m.), Bolivia. — **latona** Fldr. is a form of *hyceta*, in which the central area of the hindwing is deep red-yellow and the distal margin blackish, moreover the two posterior black spots are larger and have no white pupils. In the ♀ all the spots are larger and provided with white pupils. The under surface is as in *hyceta*, but the anterior spots of the hindwing are smaller and with white centres. From Bogotá (Colombia). — **ceryce** Hew. (43 b), likewise a form of *hyceta*, in which, however, the central area of the hindwing is red-brown and the black-brown distal margin has a breadth of 8—10 mm. In the latter are placed in the ♂♂ 4, in the ♀♀ 5 black ocelli with white pupils. Moreover, the ground-colour of the forewing is darker than in *hyceta*, hence the dark brown lines stand out less, as is also the case on the hindwing. The ♂ has the same green reflection in the middle of the forewing as *hyceta*, whilst the ♀ bears 3 white dots before the apex of this wing. The under surface is grey-brown, darker in the marginal area, with 3 fairly straight brown lines on both wings, 4 or 5 white dots instead of the eye-spots on the hindwing and some similar dots at the apex of the forewing. A black dot at the base of the forewing and 2 or 3 at that of the hindwing. From Pintue in Ecuador (800—1000 m.), Chanchamayo in Peru, and Bolivia.
- c) With three almost straight, parallel dark lines only on the underside of the hindwing. On the upperside a blue spot on each wing.
- hortona**. **P. hortona** Hew. (43 b). Ground-colour dark black-blue. The blue spot of the forewing is elongate, varying in size, 3—4 mm. broad and 6—12 mm. long, and is placed on the discocellular. That of the

hindwing is much larger, nearly round, 10–13 mm. in diameter, and extends nearly to the costal margin. At the inner margin of the hindwing there is in the ♂♂ a patch of light ochre-yellow, appressed scales 10–12 mm. in length. Under surface yellowish grey, on the forewing with 2 brown lines, contiguous in the middle and diverging anteriorly and posteriorly, and with a short oblique line in the cell, and 3 black dots near it. On the hindwing there are 3 black dots basally to the 3 almost straight parallel transverse lines and before the distal margin a row of 5 similar dots. Amazons and Ecuador. — *hortensia* Fldr. is a *hortensia*, local form which is distinguished by narrower wings, smaller blue spots on the forewing and less rounded spots on the hindwing, which are placed further from the distal margin. From the Rio Negro.

4. Genus: *Antirrhaea* Hbn.

Medium-sized and large butterflies of 65–105 mm. in expanse, mostly dark-coloured, only a few having blue, white or red-yellow markings. The palpi are densely covered with stiff hairs, the antennae thin, thickened towards the end, without distinct club. In most species the veins of the forewing are not swollen, only in *archaea* the costal vein is somewhat thickened and in *hela* distinctly swollen. In the hindwing the costal vein does not arise direct from the base, as in the preceding genera, but on a common short stalk with the subcostal. The precostal also arises at the point of separation of these veins. This is likewise the case in all the following genera of Satyrids. The principal distinguishing character of *Antirrhaea* consists in the scent-organ of the ♂♂, a brush of hairs on the underside of the forewing between median and submedian. This differs in size, shape and position in the individual species, being mostly basally pointed, anteriorly and distally rounded. The hairs are glossy, 3–4 mm. long and have the tips bent towards one another. In most species the scent-organ stands out before the costal margin of the hindwing, in single cases, e. g. in *geryon*, it even remains hidden if the forewing is much brought forward in setting. In consequence of this brush cellule 1 b is very broad between median and submedian, up to 12 mm., and the submedian and inner margin are semicircularly curved posteriorly. In the female the scent-organ is absent and the submedian and inner margin of the forewing are straight. The genus is distributed from Guatemala to South Brazil through Central and South America.

a) In the ♂♂ the subcostal and upper radial of the hindwing arise near together but separate out of the anterior margin of the cell, converge somewhat for a short distance and then diverge strongly. Hence the upper discocellular is short and only reaches $\frac{1}{6}$ to $\frac{1}{4}$ the length of the middle discocellular. The inner margin of the forewing in the ♂♂ deviates 2–4 mm. from the rectilinear. In the ♀♀ subcostal and upper radial diverge from the point of origin. Apex of the forewing rounded. Hindwing with obtuse angle at the middle or upper median (*Anchiphlebia* Btlr.).

A. *archaea* Hbn. (= *girondius* Godt.) (43 d). The genus *Antirrhaea* was founded on this species. The ♀ *archaea* is very similar to the figured ♂, except that it has the inner margin of the forewing straight. On the under surface, which is striated with yellow-brown and white-streaked, there are only small white dots instead of the eye-spots. The scent-apparatus of the ♂♂ consists of a semicircle of yellow-brown, dense hair, 3–4 mm. long, placed close above the submedian, the hairs directed anteriorly and with the points bent towards one another. The length of this brush is 10–11 mm. Opposite to the scent-organ on the upperside of the forewing there is an oval spot of flattened scales, which is the same colour as the ground, and hence may easily be overlooked. According to WILH. MÜLLER, who has obtained the young larva from the egg, but was not able to rear it, as it would not touch the grasses, etc., placed before it, the egg is semicircular, the surface divided by raised ridges into regular, hexagonal areas. The body of the larva when first hatched is 3.8 mm. long, the tail-fork with the terminal bristle 2.7 mm., thus proportionately very long. Head large, black, rugose, covered with bristles, above with a bipartite process. Body thinner than the head, white with red-brown prothorax and brownish or reddish dorsal and lateral lines. The tail-fork is black. Widely distributed in Brazil: Bahia, Espirito Santo, Santa Catharina, Rio Janeiro.

A. *taygetina* Btlr. Similar to the preceding species, but somewhat smaller, with only 2 smaller *taygetina*. ocelli on the forewing, whose pupils are shifted distad and which are placed in the ochre-yellow band. Sometimes there is further a third very small ocellus at the costal margin. Ground-colour brown-grey; hindwing in the distal half dark brown with 2 to 4 light blue or light violet spots. Beneath light ochre-yellow, sometimes rose-reddish with 2 brown median lines, diverging at the costa of the forewing, of which the outer one is distally margined with white, with an indistinct, undulate, brown submarginal line and 5 white dots on both wings in an angular row. From Massauary, Teffé, Coary and Pebas on the Amazon. Rare.

A. *hela* Fldr. (43 b). Upper surface dark brown. The forewing has before the apex 2 white spots *hela*. with blue rings and in the posterior half of the wing 3 blue spots, of which the first 2 have white pupils. All 5 spots are placed in a row. In the neighbourhood of these spots the dark brown ground-colour has a blue reflection. Hindwing without markings. The under surface is grey-brown, finely striated with dark

brown, and has a slight violet reflection. The scent-organ of this species is elliptical in form, with one side pointed. This proximal point is placed in the angle of the submedian. The scent-organ is 13 mm. long and 6 mm. broad. The rather stiff hairs are placed close together at the margin and radiate inwards, so that their tips meet over the middle of the ellipse. Only the basal half of the anterior margin of the ellipse is free from these hairs. The hairs themselves are 4 mm. long, light yellowish brown, darker brown at the tip. Opposite to the scent-organ is placed on the upperside of the forewing a wedge-shaped patch of flattened scales. From the Upper Amazon, Ecuador and Peru. Rare.

ornata. **A. ornata** Btlr. Expanse 75 mm., thus somewhat larger than *hela*. Violet-brown. Forewing with a row of 4 large, connected, round, black ocelli with rather large white pupils and ochre-coloured bordering. Hindwing with a curved continuous row of 5 large oval blue ocelli which have fine white pupils and are placed in thick black rings. This row is likewise surrounded with ochre-yellow. The under surface is ochre-yellow, finely striated with brown. The obtusely projecting angle of the hindwing is placed on the upper median vein. Only the ♀ is known. Cayenne. Rare.

b) Subcostal and upper radial of the hindwing in both sexes arise far apart and divaricate. Upper discocellular half the length of the middle one. Inner margin of the forewing in the ♂♂ only deviating 2—3 mm. from the rectilinear, in the ♀♀ quite straight. Apex of the forewing rectangular. Hindwing running out to a point on the upper median, obtusely angled on the middle and lower median.

geryon. **A. geryon** Fldr. (43 c). Expanse 85 mm. The distal margin of the forewing is almost straight, the greatest bend of the inner margin in the ♂ lies somewhat before the middle and only attains 2 mm., in the ♀ the inner margin of the forewing is straight. Ground-colour brown. Three large black eye-spots measuring 5—6 mm., with white pupils 1 mm. large and brownish ochre-yellow bordering, are placed on each wing, those of the hindwing in a curved row. In the ♀ the eye-spots measure 8—9 mm. The under surface is brownish ochre-yellow, everywhere finely striated with brown, with brown median band on both wings, two brown half-bands in the cell of the forewing, a similar half-band before the median band of the hindwing and brown distal margin. In place of the eye-spots the forewing has three white dots and the hindwing two white dots and a black one. There is further a black dot at the base of the hindwing. The scent-organ is only 10 mm. long, is placed 4 mm. from the base and consists of a row of yellow-brown hairs on the submedian, 3 mm. in length, with dark brown tips. It does not quite reach the middle of the inner margin and is consequently concealed by the hindwing even when the fore wing is set very high. Opposite to the scent-organ is placed here also on the upperside of the forewing a pear-shaped patch of flattened scales, which is 7 mm. long and 5 mm. broad, but may easily be overlooked. Moreover, a small, bare, scaleless patch at the costal margin of the hindwing may be mentioned as the so-called friction-patch. — The earlier stages of this species have been observed by FASSL in Colombia: The egg is hemispherical, white, not shiny; the base somewhat incised. Of the same size as that of *Harpyia vinula*. The larva looks almost like that of *Bomb. neustria*, with similar variegated and well-defined markings, but with diverging dorsal lines. The very large head is yellowish green, the body posteriorly narrowed and terminating in a long forked tail. The pupa is somewhat stouter, otherwise similar to a large *Pyram. atalanta*-pupa. Some are green and some brown, the variation being independent of the sex. Food-plant of the larva a species of palm. Colombian West Cordillera, or more exactly: Carmen 1800 m., valley of the Rio Agua, 1800 m., from November to January, St. Antonio, 2000 m., in April in dense, dark, primeval forests at the passes. Huamboya in Ecuador (1200—2200 m.).

geryonides. **A. geryonides** Weym. (43 c). Similar to the preceding species, but the ground-colour is dark olive-brown, the distal half of the forewing and the hindwing especially dark. The eye-spots are larger, in the ♂ measuring on the forewing 8—9 mm. in diameter, on the hindwing 5—6 mm. Their pupils are likewise larger (2—2½ mm.) and bluish white. The red-yellow bordering of the ocelli in *geryon* is here entirely absent. The under surface is likewise darker than in *geryon*. The white dots on the forewing are somewhat larger and instead of the black dot between the middle and lower median vein of the hindwing there is a small black ring with white pupil. One of the principal differences is found in the scent-organ. This is much larger than in *geryon*, covering a wedge-shaped, proximally pointed, distally rounded area of 18 mm. in length, its greatest width being 6 mm. Hence even when the wing is not set very high the distal part of the scent-organ lies free and only the proximal ¾ are covered by the hindwing. The hairs are arranged in two longitudinal rows and in the rounded distal part are placed close together, bending towards one another with the tips touching. The patch of appressed scales placed opposite to the scent-organ on the upperside of the forewing is of the same shape as in *geryon* and is distinctly visible. The ♀ attains an expanse of up to 90 mm. The ocelli on the wings are even larger than in the ♂, measuring 10—12 mm. on the forewing, 7—10 mm. on the hindwing. The bluish white pupils reach 2—3 mm. in size. On the hindwing there is, moreover, a 4th smaller ocellus, which occupies a different position in the two ♀♀ before me. In the Ecuador example it is placed between the lower radial and the upper median vein, but in the Colombian example near the costal margin. Moreover, the ground-colour in the latter is

darker than in the former, yet both are easily distinguished from *geryon* by the large bluish white pupils. Ecuador (Sarayaku and Makas); Colombia (Rio Toche at the Quindiu, 2200 m. in September, and Cañon del Tolima, 1700 m., in December).

c) Apex of the forewing as if truncate, the distal margin obtusely angled at the upper radial. The inner margin of the forewing in the ♂♂ deviating 4—6 mm. from the rectilinear. Otherwise as in b.

A. phasiane Btlr. (43 c). Size about the same as in the preceding species, pattern also similar, but *phasiane*, the apex of the forewing is as if were truncate, so that the distal margin forms an obtuse angle below the apex. The inner margin of the forewing in the ♂ deviates 4 mm. from the rectilinear; ground-colour reddish brown. Forewing with 3 large, white-centred ocelli, of which the anterior one has 2 pupils (one near to the edge). Hindwing with 4 round black spots in place of the ocelli. On both wings the ocelli and spots are surrounded by brownish red-yellow. The under surface is almost like that of *geryon*, but the ground-colour is reddish brown, the distal margin is not darker and before it stand out distinctly on each wing 4 white spots, which correspond to the pupils and spots of the upper surface. The sexes do not differ in colouring and markings. Venezuela (Maracaibo); Peru (Chanchamayo).

A. pterocopha Godm. & Salv. The shape of the wings and the scheme of markings on the underside *pterocopha*, is very similar to that of *phasiane*. But the upper surface is widely different and much more brightly and finely coloured. Moreover, the two sexes differ considerably above in the markings. ♂ 95 mm. in expanse. The inner margin of the forewing is more strongly excurved than in *phasiane*, deviating 6 mm. from the rectilinear. Forewing above dark brown with 3 grey dots in cellules 3, 5 and 6, and with an oval patch of flattened scales close above the submedian, which is widely curved posteriorly. Hindwing with a large, orange-yellow, horse-shoe-shaped spot at the apex, a large blue spot, 20 mm. in length, at the anal angle, which occupies almost the entire distal half of the inner margin as far as the lower median vein, and with 2 smaller blue spots in cellules 2 and 3, of which the latter is a mere dot. The under surface is similar to that of *geryon* and *phasiane*, yellowish brown, finely strigulated with dark brown, with brown, somewhat curved median band on both wings, 2 brown half-bands on the forewing in the cell and a brown basal band on the forewing, which is posteriorly divided into several parts. All these bands are accompanied at the distal side by lilac-coloured stripes, which fade off into the ground-colour. In the marginal area 3 white dots on each wing. ♀ 100 mm. in expanse. The inner margin of the forewing is not straight as in the other species of *Antirrhaea*, but somewhat excurved, yet the curvature only amounts to 3 mm., thus only half that of the ♂. Ground-colour dark brown; forewing behind the middle with a lilac transverse band, which, gradually narrowing, extends from the costal to the inner margin, is interrupted in cellule 4 and on which white dots are placed in cellules 2, 3, 5 and 6. The hindwing has the anterior half of the distal margin red-yellow for a breadth of 11—12 mm. with a brown submarginal stripe. From the upper median vein to the anal angle the red-yellow distal margin is only 4 mm. in breadth. In cellule 3 there is a larger, in cellule 5 a smaller lilac spot, the former on a brown, the latter on a red-yellow ground, both with a white centre. Costa Rica, Panama (Santa Fé, Calobre). Very rare.

d) Apex of the forewing rounded, inner margin of the forewing in the ♂♂ so strongly excurved that it deviates 7 to 10 mm. from the rectilinear. Hindwing at the upper median vein produced into a point, at the lower obtusely angled.

A. philoctetes L. (= *morna* F.) (43 c). Forewing unicolorous brown with a white dot before the apex. *philoctetes*, The patch of flattened scales does not differ from the ground-colour, is large, oval, 12 mm. long and 7 mm. broad and stands out rather distinctly. Hindwing brown, at the costal margin lighter, distally and posteriorly darker, a blue spot at the anal angle, followed by 2 large oval spots of the same colour, which have a thick black centre, then a blue dot in cellule 4 and two white dots in cellules 5 and 6. On the under surface the forewing is grey-brown with 2 straight brown transverse lines in the cell and a straight white stripe behind the middle, which is only bent on vein 2 and terminates before the scent-organ. On both sides of this stripe the ground-colour is somewhat darker. The scent-organ is circular, the hairs placed at the edge of the circle are directed towards its centre and the tips touch one another. Even when the wings are not set very far forward the anterior part of it remains free. Through the middle of the hindwing runs a dark brown band 15 mm. in breadth from the costal to the inner margin, in the marginal area in cellules 2 and 3 there are two black spots margined with light brown and in each of cellules 4, 5 and 6 a white dot. A brown undulate line before the distal margin. Guiana, Lower Amazon, Tapajos. — **scoparia** Btlr. only differs from *philoctetes* in that the forewing has above a lighter brown *scoparia*, ground-colour, the markings of the underside showing through distinctly, and that on the hindwing basally to the blue macular band of *philoctetes* there is a second band consisting of 4 spots. On the underside of the hindwing the 2 dark spots in the marginal area are nearly joined to the brown median band. Described from an example from the KADEN collection, now in coll. GODMAN, of which the locality is not known.

- philaretetes*. **A. philaretetes** Fldr. (43 d). The forewing is quite similar on both sides to that of *philoctetes* and the shape of the scent-apparatus is exactly the same, but the hindwing is very different. It has in the ♂ 2 round blue spots of 4 mm. diameter in cellules 2 and 3 and a dot of the same colour in cellule 5, in which is placed a fine white pupil. Sometimes there is a 4th spot between them. In the ♀ this is probably always the case. On the under surface the white band of the forewing is continued fairly straight across the hindwing, extending close to the inner margin near the anal angle. On it is placed in cellule 2 a small round black spot and near it at the distal side in cellule 3 a similar, larger spot surrounded with white. At the base of the hindwing 3 small brown spots. From Bogotá in Colombia and Pebas on the Upper Amazon. — **philopoemen** Fldr. Larger than *philaretetes*, the ♀ attaining 100 mm. in expanse. Ground-colour brown, on the forewing behind the middle a straight white band, before the apex 2 white dots, a brown submarginal line, behind which the margin is reddish. The hindwing in the distal half blackish with violet reflection and 6 oval, glossy blue spots between the lower median and the costal margin, with reddish, sometimes white-spotted crescents at the distal margin. The under surface is similar to that of *philaretetes*, but the basal half of the forewing is considerably lighter, the white band is broader on both wings, but on the hindwing it reaches only the submedian, not the inner margin. From Villeta, Cordillera of Bogotá. 1500 m. Rare. — **avernus** Hpff. (43 d). Similar to *philopoemen*, but somewhat smaller: ♂ 78—85 mm., ♀ 90 mm. in expanse. The inner margin of the forewing in the ♂ is more strongly curved distally. The deviation from the rectilinear amounts to 10 mm. Forewing in the ♂ unicolorous brown with only one white dot before the apex, in the ♀ in addition behind the middle with a narrow, dull white transverse stripe, interrupted at the veins. The hindwing has in both sexes 3 large, bright blue or violet-blue spots between the submedian and the 3 median veins, which almost entirely fill up the width of the cellules and are 8—11 mm. in length. The largest is nearest to the inner margin. In the ♀ there are further in the anterior half of the wing 2 or 3 small blue spots, in the ♂ only one between the radials, which has a white central dot. The under surface is quite similar to that of *philaretetes*, and likewise the scent-organ. This form may be distinguished at once from its allies by the large blue spot between the submedian and the lower median vein on the upperside of the hindwing. Peru (Chanchamayo), Ecuador (Macas and Sarayacu).
- miltiades*. **A. miltiades** F. (= casta *Bates*, *lindigi* Fldr.) (43 d). 80—90 mm. span. Forewing in the ♂ brown with 1 or 2 white dots before the apex. These are somewhat larger in the ♀, which bears moreover a narrow white band running from the costal to the inner margin. Hindwing brown, in the ♂ with an irregular white spot between the median veins, which is posteriorly prolonged into a point. In the ♀ this spot is falcate and there are several small spots before and behind it, and on the distal margin white crescents are placed between the veins. The under surface is quite similar to that of the preceding species, but the white band between the median veins on the hindwing is somewhat widened, so that a white spot is formed here, which is similar to that on the upper surface. In this are placed 2 round black spots, one of which is sometimes a mere dot. At the base three brown dots. The scent-organ as in the preceding species. From Guatemala, Nicaragua, Costa Rica, Panama, Colombia (Muzo). — **murena** Stgr. is a local form of *miltiades*, distinguished by its smaller size (70 mm. expanse) and by having the white spot on the hindwing divided into two parts by the central median vein, so that only the white bordering of the black spot placed beside it remains. Moreover, the white bands of the underside show through somewhat above, the base of the hindwing is light brown above and at its apex there are 2 grey dots. On the under surface the distal part of the basal area is lighter brown, the white band is a trifle broader on the forewing, but the widening of this band between the median veins on the hindwing is almost entirely absent, whilst the black spot at this place is much enlarged. From Massauary on the Rio Maues (Lower Amazon). — **tomasia** Btlr. (43 d). Expanse 80—95 mm., is a form similar to the preceding two, in which the white spot on the hindwing between the median veins is entirely suppressed, but instead there is sometimes a small white dot in cellule 5. The costal margin of the hindwing is light grey, as in all the allied forms, and before the apex of the forewing are placed 2 white dots. On the under surface the white stripe on the forewing is much narrower than in *miltiades*, on the hindwing it is entirely absent as far as the upper median vein. Then follows in cellule 3 a white spot measuring 3 mm., which is almost entirely filled up by a round black spot. Between the central median vein and the inner margin the white stripe is present, but quite narrow and interrupted several times. The median area of the hindwing beneath is darker than the marginal and basal areas. From Panama (Chiriqui, Bugaba, Veragua).

Note. Whether *Antirrhaea bifasciatus* Gmelin cited by KIRBY in his Catalogue really belongs to the genus *Antirrhaea* or even to the American fauna, appears questionable, as it cannot be recognized from the description and the locality was not known to the author. The species is only designated as exotic, and hence may just as well belong to the Indian or African fauna. The original of the description was in the Museum Leskeanum, and no further example is known. According to this description the wings are angled, brown above, and the under surface is grey with 2 common brown stripes and a broad grey common band, posteriorly dentate, in which on the forewing on a brown ground are placed 5, on the hindwing 6 ocelli with white pupils and yellow iris. Of the eye-spots on the forewing the middle ones are larger. Habitat extra-European (GMELIN, Syst. Nat.).

5. Genus: **Sinarista** Weym.

The distinguishing characters of this genus are the absence in the male of the tuft of hairs between median and submedian on the under surface of the forewing and the form of the submedian of the same wing, which is only elbowed at the base, otherwise almost rectilinear, and only reaches the distal margin in the rounded inner angle, whilst in *Antirrhaea* it describes a more or less extended curve and runs into the inner margin far before the inner angle. The inner margin of this wing is likewise little curved posteriorly, the distal margin forms a straight line and the apex a right angle. The distal margin of the hindwing is produced into a distally directed point at the upper median vein, at the other veins it is only undulate. The single species of this genus has a very dusky appearance and is quite a recent discovery.

S. adoptiva Weym. (44 a). Expanse 82 mm. The shape of the wings is that of *A. geryon* Fldr.-♂, *adoptiva*, but the ground-colour even darker brown than in *A. geryonides* Weym., almost black-brown and uniformly dark all over. On the forewing are placed in cellules 2, 3 and 5 three black eye-spots with white pupils, the upper one measuring 5 mm., the two lower only 3 mm. in diameter; on the hindwing in the same cellules three black spots without pupils, the anterior and posterior spots round, 5 mm. in diameter, the middle one oval and somewhat larger (6 to 8 mm.). These spots stand out but little from the dark ground-colour, sometimes the two posterior ones have fine, scarcely visible, white-grey pupils. The distal margin of both wings is finely bordered with red-brown, the tips of the fringes white. The under surface is dark brown covered with many fine bluish white dots, which mostly consist of single scales and at the costal margin of the forewing are condensed into a few white spots. Distally this dusting disappears, so that the margin appears unicolorous brown. In place of the eye-spots there are on the upper surface of the forewing three ochre-yellow dots, the anterior one somewhat larger, and on the hindwing in place of the middle spot a small bluish white spot. Discovered by FASSL in the Colombian West Cordillera. The ♀ of this species is not yet known.

6. Genus: **Caerois** Hbn.

This genus also is distinguished by the possession in the male of a scent-organ at the inner margin of the forewing beneath, moreover on the upperside of the hindwing in the middle of the submedian there is a hair-tuft which consists of a row of brown hairs. The male forelegs are much reduced, the palpi rather long, with thin, curved middle joint, densely scaled anteriorly. The veins are not swollen. In the ♂ only one subcostal vein arises before the end of the cell on the forewing. The hindwing runs out into a tail at the upper median vein, at the submedian it shows an obtuse angle. The other veins do not project on the distal margin. Large butterflies of 80—90 mm. expanse, whose habitat is Central and northern South America.

C. chorinaeus F. (= *arcesilaus* Sulz.) (44 a). The costal margin of the forewing is strongly curved *chorinaeus*, posteriorly at the apex, the apex itself broadly rounded, the distal margin deeply incised below the apex, the inner angle rounded, the inner margin somewhat projecting. Ground-colour brown with broad red-yellow oblique band, without eye-spots, only with a white dot before the apex. The distal margin of the hindwing has a red-yellow border 2—4 mm. in breadth, the brown point at the upper median vein projects horizontally distad. The brownish ochre-yellow under surface is finely striated with dark brown, with three brown, almost straight and parallel transverse lines on the forewing, of which the middle one only reaches to the median, the hindwing with two lines running in the same direction, which extend from the costal margin to below the middle of the wing, and a third straight line, which connects the apex with the anal angle. The scent-organ of the ♂♂ is placed close to the inner angle on the upper surface of the forewing, so that it is not covered by the hindwing; it is 12 mm. long, 8 mm. on the inner and 4 on the distal margin. The anteriorly directed hairs of this scent-organ are 3 mm. long, and dark brown. In addition there is a small brown hair-tuft on the upperside of the hindwing near the inner margin. — STOLL has figured the larva and pupa of this species in the supplement to CRAMER's exotic work, pl. VI, fig. 1 and 1a. The larva has at the posterior end of the body two points of extraordinary length. The body of the larva is 60 mm. long, the points measure 30 mm., thus reaching half the length of the body; they stand straight out posteriorly and are covered with small, fine hairs, whilst the larva itself is naked. The head is proportionately large, red-brown with yellow margins and stripes, the mouth-parts black. The body bears no protuberances, is 5 mm. thick anteriorly and posteriorly and 7—8 mm. in the middle, and very gaily marked. Ground-colour reddish violet, venter and legs yellow; on the dorsum a yellow longitudinal stripe, which is broad in the middle of each segment but narrow in the incisions, so that elongated quadrangles are formed, on which are placed darker yellow and blackish markings and which at each side of the dorsum are bordered by several red-brown and yellow undulate lines. The pupa is suspended, about 22 mm. long, 9 mm. thick, with the abdomen much bent. It shows no sharp-edged

protuberances, but only a flat rounded elevation on the middle of the dorsum. Wing-cases and ventral side are unicolorous light brownish grey, the dorsum on the contrary has a yellowish brown colour and is densely covered with many small black transverse streaks and spots. The food-plant of the larva is the sugar-cane. The butterfly appears from the pupa in 11 days. It occurs in Guiana and the whole Amazon region.

gerdrudtus. **C. gerdrudtus** F. (= *gertrudtus* Godm. & Salv., *vespertilio* Thieme) (44 a). The costal margin of the forewing is not bent so far back as in the preceding species and runs out into a rather sharply produced apex, yet the distal margin is only a little incurved. Ground-colour brown with dark violet reflection from the base to beyond the middle of the wing. Before the apex of the forewing a large black eye-spot with white pupil, proximally bordered by a red-yellow crescent, below this a red-yellow spot. In the figured ♀, somewhat nearer to the inner margin, is placed a second smaller eye-spot of the same colour with complete red-yellow ring. This second eye-spot is absent in the ♂. On the hindwing the dark violet reflection is extended nearly to the distal margin. The pattern of the under surface is very similar to that of *chorinaeus*. The brown transverse stripes proximally shade off imperceptibly into the ground-colour, distally they have lighter borders. The scent-organ is not placed at the inner angle as in the preceding species, but much further basally at the inner margin. It begins 8 mm. from the base, has a length of 18—19 mm. and terminates 5 mm. before the inner angle. It consists only of a row of stiff, closely approximated hairs, which are directed anteriorly, 6—7 mm. long, somewhat crimped at the tip and of yellowish brown colour. The submedian is covered by these hairs and terminates at the end of the scent-organ in the inner margin, which is much excurved. Also in this species there is a small, short hair-tuft at the middle of the submedian near the inner margin on the upperside of the hindwing. From Panama (Lion Hill), Costa Rica (Santa Clara Valley), Ecuador (Balzabamba), Colombia. — As BUTLER has compared the figure of this species (which is one of the unpublished figures of JONES, used by FABRICIUS in describing the species) with the example in SALVIN'S collection and found them to agree (cf. BUTLER, Catal. of Diurnal Lepid. described by FABRICIUS, p. 9), I have no hesitation in retaining the name *gerdrudtus* Fabr.

7. Genus: **Tisiphone** Hbn.

Forewing with rounded apex, the distal margin slightly undulate, on the hindwing more strongly undulate. The lower discocellular on both wings is at least twice as long as the middle and upper discocellulars. The palpi are densely scaled, the antennae with indistinct and weakly thickened club. The claws of the middle and hindlegs are bipartite. Medium-sized and rather large brown butterflies with white macular band on the forewing and a row of eye-spots on the underside of the hindwing. The range of distribution extends from Mexico to South Brazil.

hercyna. **T. hercyna** Hbn. (= *anosia* Godt.) (44 b). Brown, darker in the distal half of the wing, with a row of large white spots through the middle and a small spot before the apex of the forewing, as well as some similar spots at the margin of the hindwing. Costal, median and submedian of the forewing are somewhat thickened at the base. On the under surface the ground-colour is somewhat lighter, brownish grey, the white spots as above, the hindwing with several dark brown, strongly dentate lines, behind the middle with a curved row of 6 large, round, white-centred ocelli, of which the 2 anterior ones have black, the 3rd, 4th and 5th grey-brown iris, but the last is doubly pupilled with black. All the ocelli are surrounded by a yellowish grey ring and outside that by a dark brown one. The apex of the forewing is beneath likewise brownish grey with an eye-spot which is coloured like the anterior one on the hindwing. Habitat: South Brazil (province of Santa Catharina, province of Parana, Rio de Janeiro, in certain years in great abundance), Mexico.

maculata. **T. maculata** Hpff. (44 b). Similar to the preceding species, but considerably smaller, the ground-colour somewhat lighter, the white spots on the forewing are much smaller above and beneath, are isolated, and form a more outcurved series. On the hindwing they are entirely absent. The under surface of the hindwing is much lighter than in *hercyna*, otherwise with similar markings. Habitat: Mexico, Guatemala, Nicaragua, Costa Rica, Panama, Colombia, Venezuela, Bolivia, South Brazil (Rio Grande do Sul).

Note. *Tisiphone lyssa*, described by BURMEISTER, is = *Pedaliodes* (*Pronophila*) *porina* Hew.

8. Genus: **Enodia** Hbn.

Butterflies somewhat below medium size. The costal vein of the forewing is not strongly, but yet visibly, swollen at the base, the upper discocellular is very short, the middle one less than half the length of the lower. In the hindwing the costal vein does not reach the apex. The distal margin on the forewing is weakly undulate and below the middle somewhat incurved, that of the hindwing being more strongly undulate with an obtusely projecting tooth at the upper median. The antennae are light

and dark ringed, with dark club, which is not abruptly but still distinctly thickened, and light tip. Palpi long and thin, densely haired anteriorly. Eyes hairy. Forelegs in both sexes much aborted. The genus consists of two North American species, one of which was for a long time regarded as a variety of the other, until SKINNER described it as a separate species. The other, the well-known *portlandia*, was referred by WESTWOOD to the genus *Debis* (= *Lethe* Hbn.), by KIRBY with? to the genus *Euptychia*. DYAR in his catalogue introduces HÜENER's name *Enodia* for it. The neuration of the butterflies agrees with the Indian genus *Lethe*, but the shape of the larva differs in that the head in *Lethe* bears one horn, in *Enodia* two.

E. portlandia F. (= *andromacha* Hbn.) (44 b). Expanse 48—51 mm. The black spots of the upper *portlandia* surface, which are here non-pupilled, with brownish yellow borders, have beneath mostly white pupils and a dark brown second ring as border; also their number is increased by one, a small double eye-spot being present at the anal angle. In the basal area on both wings a somewhat curved brown line, a second strongly dentate brown line through the middle of the wings, a narrow brown submarginal band and two fine brown marginal lines, between which the margin is filled up with ochre-yellow. — The larva is slender, narrowing to a point from the middle to the anus, green, with a red dorsal and a dark green lateral line. The head is bipartite, each part bears a short conical horn; the last abdominal segment with two posteriorly directed points. On grasses. The pupa concave on the dorsum, convex on the ventral side, with an obtuse elevation on the thorax, light green. The butterfly is distributed in the United States from the east coast to the Rocky Mountains and from Maine in the north to the Gulf of Mexico in the south.

E. creola Skinner. Similar to the preceding, but larger, ♂ and ♀ 57 mm. expanse. Forewing in the ♂ *creola* more elongated, at the costal margin more convex, at the distal margin more concave. Ground-colour darker grey-brown, the black spots on the forewing not margined with brown-yellow, at both sides of the veins on the forewing are placed long cottony dark brown spots, which are proximally connected, distally pointed. On the hindwing the black spots are all of the same size. In the ♀ the brown-yellow bordering of the black spots is broader than in *portlandia*. Occurs along the Gulf of Florida to Mexico. Rare. As I do not know *creola* in nature, I leave the question undecided whether it is a good species or only a local form of *portlandia*.

9. Genus: **Taygetis** Hbn.

This genus consists of large and medium-sized butterflies, and also some below medium size. The largest species measure 95—100 mm, the smallest 48—50 mm. The ocelli are naked; the palpi with strong, bristly hairs. Antennae thin with feebly thickened club. The costal and median veins of the forewing are swollen at the base. Two subcostal veins on the forewing arise before the end of the cell and two beyond it. The upper discocellular is rather short, much shorter than the middle discocellular, this and the lower one are of equal length. In the hindwing the upper discocellular is almost as long as the middle, the lower on the contrary mostly somewhat longer. The forewing is either smooth-margined, with the apex either rounded or produced, or the apex appears truncate, an obtuse angle being formed at the upper radial. The hindwing is more or less strongly dentate, in many species the dentition extends over the whole distal margin, in others only on the posterior part. Mostly the most strongly projecting tooth is placed on median 2, but in single species on median 3. With but few exceptions the upper surface is unicolorous brown. The few known larvae live on species of bamboo. The range of distribution extends over the whole of tropical America, northwards to Mexico and southwards to South Brazil.

T. mermeria Cr. (44 c). The largest species of the genus and very variable in the shape of the *mermeria* wings and the pattern of the under surface. The name-typical form has the apex of the forewing rectangular, sometimes somewhat rounded. The distal margin of the forewing is smooth, that of the hindwing undulate with blunt angles. Upper surface unicolorous olive-brown. Fringes sometimes olive-brown, sometimes brownish white. The under surface is very variable, mostly it is grey-brown with a narrow, straight, whitish median band through both wings. Beyond this a row of 5—6 dark ocelli on each wing, of which, however, often only the white pupils are visible. Sometimes also the lighter band is wanting, especially on the forewing, or it is only indicated by a lighter shading, before which a broad dark brown median band runs through both wings. The species has a wide distribution and is locally not rare. Mexico, Guatemala, Honduras, Nicaragua, Costa Rica, Ecuador, Peru, Amazons, Bolivia, British Guiana, Surinam, Brazil. The butterfly flies in the lowlands in the shadow of the woods near the ground and is difficult to distinguish from the dry, fallen leaves on which it is fond of resting. — **cramerii** (Stgr. i. l.) form. nov. (44 c) is a form of *mermeria* *cramerii*. in which the underside of both wings is for the most part reddish ochre-yellow and some of the eye-spots on the forewing are much larger and likewise ochre-yellow; sometimes they are so on the hindwing also. From Mexico and South Brazil. — **tenebrosus** Blanch. (44 c), likewise a form of *mermeria*, in which the forewing is *tenebrosus* produced at the costal margin into a fine point several millimeters in length and the eye-spots on the under surface of the forewing are mostly only small. The hindwing has beneath before the middle a light brownish

yellow or light brownish grey band of 10 mm in breadth, sprinkled with dark brown dots. This form occurs in Mexico, in Honduras and other countries of Central America, on the Amazon (Ega), in Ecuador, Surinam and South Brazil (Blumenau). — *excavata* Btlr. (44 c), a further form of *mermeria*, is distinguished by having the posterior part of the hindwing rather more deeply excised at the distal margin between veins 1 b and 3. The forewing is likewise produced into a long point at the costal margin. From Honduras and Colombia¹⁾.

armillata. **T. armillata** Btlr. is intermediate between *mermeria* and *ypthima*. Somewhat smaller than the former. Expanse 90—95 mm. The forewing runs out into a point, which is not so elongated as in *tenebrosus* and *excavata*. The hindwing is produced into sharp teeth at veins 1 b to 4. Upper surface olive-brown, the margin somewhat darker, the ciliae lighter. The principal difference from *mermeria* lies in the position of the median band on the underside of the hindwing. This band is not straight as in *mermeria*, but curved and running parallel with the distal margin. The eye-spots on both wings are much smaller and those of the forewing are placed in a nearly straight row. From Colombia, Ecuador, Bolivia. — *jimna* Btlr. (44 d) is a form of *armillata*, which only differs in the lighter colour of the under surface and in the less angled, more prominent transverse band. From Panama, Thauropolis.

larva. **T. larva** Fldr. (46 a). Somewhat smaller than *armillata* (80—85 mm expanse). Upper surface unicolourous dark olive-brown, the apex of the forewing somewhat produced. The teeth on the hindwing are somewhat less prominent than in *armillata*. The under surface dusted with steely black-grey, especially the hindwing, which is slightly glossy. The transverse bands are very narrow, but quite as much curved as in *armillata*. From Colombia (Bogotá) and Paraguay. The figure is taken from FELDER's type in the Tring Museum.

ypthima. **T. ypthima** Hbn. (= *chelys* Burm.) (44 d). Forewing with pointed apex, below this the distal margin somewhat incurved. Hindwing with pointed teeth on veins 1 b to 4. Upper surface olive-brown, with dark brown border about 3 mm in breadth. Cilia yellowish grey. The under surface is very variable, in the typical form brownish yellow, finely marbled with brown, on the forewing with 2 lilac-coloured transverse bands, between and behind which the ground-colour often becomes dark brown. On the hindwing two darker, somewhat curved dentate transverse bands and a row of whitish dots, which are surrounded by brown rings. Of these the one which is placed in cellule 2 often stands out as a distinct white spot. Modifications occur of the most varied kinds. The transverse lines become broader, are united into brown spots, and these again into brown longitudinal stripes. Distributed in South Brazil, province of Rio de Janeiro (Petropolis), province of St. Catharina (Joinville, Blumenau), province of Rio Grande do Sul (Porto Alegre), Paraguay. — *ophelia* Btlr. (44 d) is a form of *ypthima* with almost unicolorous, brownish ochre-yellow under surface to the hindwing, with somewhat lighter but indistinct median band and small black dots in yellow rings. From Joinville. — *xantippe*. **xantippe** Btlr. (44 d) has the under surface of the hindwing almost entirely brown with a large reddish yellow area at the apex and a spot of the same colour in the middle. From Blumenau. — *semibrunnea* form. nov. (44 d) is a further form of *ypthima* with yellowish grey, brown-dusted hindwing, which has an abbreviated brown basal band and a brown median band extending from the costal to the inner margin. Moreover, the whole distal margin is broadly dark brown nearly to this band, so that between the two there only remains a narrow stripe of the ground-colour, which is interrupted in places. From Blumenau. — The egg and the first 4 stages of the larva of true *ypthima* were described by MÜLLER. The egg, which is laid by the butterfly on the underside of the bamboo leaves, is globular, divided by low ridges into hexagonal areas. The larva in the first stage is 5—8 mm. long. Head light brown, rugose, with 2 horns divided at the tip and 3 conical elevations at each side, each of which is provided with a stiff, clavate, bristle. The horns are whitish at the base, blackish brown at the tip. The body is much narrower than the head, whitish green, the middle segments somewhat thickened, covered with isolated, short, finely clubbed bristly hairs. The anal tail-fork is short. In the second stage the whole head is covered with bristle-bearing tubercles, anteriorly there are 2 brown parallel curved marks, of which the proximal one disappears in the later moults; moreover, on the body there are a white dorsal line and one, later two white lateral stripes. In the 3rd and 4th stages the lateral points on the head become gradually shorter, whilst the upper points of the horns remain. In the 4th stage the head is pale grey, margined with brown. Between the horns is placed a black-brown spot, which is narrowed posteriorly and passes into the dark grey dorsal stripe. This is alternately narrow and wide, and forms with the anteriorly yellow-green, posteriorly orange-yellow subdorsal stripes and the green and white lateral stripes a very complicated pattern. MÜLLER

¹⁾ Whether the larva which STOLL figures in the supplement to CRAMER, Utitl. Kapellen, pl. 7, fig. 1, really belongs to *mermeria* Cr., appears to me somewhat questionable, as its shape does not correspond to that of the known Satyrid larvae and also the food-plant of this larva (the orange tree) leads one to suspect a mistake. Otherwise only grasses, bamboo and sugar-cane are known as food-plants for the Satyrid larvae. The larva figured is 42 mm long, 7 mm thick; on the dorsum red-brown with white, zigzag longitudinal stripe and with seven long, red and white, hairy spines; on the sides are placed white hairs, which cover the legs. At the anal end two tufts, which likewise bear red and white hairs. The head is triangular, with black and white hairs; on the frons two white stripes which run up sideways from the white mouth-parts to the frons and are joined into a point above. Food-plant: orange tree. The pupa is hung up perpendicularly, 30 mm long, 12 mm thick, with two short points on the head, green in colour and yields the butterfly in 14 days. Further investigations must decide whether STOLL's figure really represents the larva of *mermeria*.

was not able to observe the larvae (which were fed on bamboo leaves) any further, being obliged to leave the locality. Concerning the full-grown *ypthima*-larva, however, Herr SCHMALZ of Joinville tells me that it is green and has a broad grey-yellow longitudinal stripe on the back, which is bordered with yellow brown. The head is brown-yellow, with two lateral horn-like processes, which bear fine spines. The anal end is long-forked, the ends of the fork with grey woolly hairs and rolled-up. The larva feeds on *Crissimma*, a species of bamboo. I have not yet received a description of the pupa; but Herr SCHMALZ remarks with regard to the butterfly that it is almost exclusively met with in dark forests near the ground, also it sometimes comes into houses at night. In December 1887 the butterflies were observed flying at dusk in hundreds from south to north from one wooded district to another, low above the ground. Since then they have only been seen singly.

T. rectifascia Weym. (45 a). The apex of the forewing is not or only very little produced, and the teeth of the hindwing are much more obtuse than in *ypthima*. Upper surface unicolorous brown. The under surface is as variable as in *ypthima*, but it may be at once distinguished from the latter by the straight median band of the hindwing, dusted with whitish yellow or brownish. This band is bordered on the proximal side by a straight, dark brown line or a narrow brown stripe. In the marginal area of each wing 5 small, brown, white-centred eye-spots, of which the posterior one on the hindwing is somewhat larger than the others. The brown spot at the apex is absent in other specimens. South Brazil (Blumenau). — **stigma** Weym. is a form of *rectifascia*, in which the straight light band on the underside of the hindwing is dusted with grey, in place of the eye-spot in cellule 5 is placed a white spot 2—3 mm in size and instead of the eye-spot in cellule 6 a white dot. Likewise from Blumenau. — In **latifascia** Weym. (45 a) the ochre-yellow band on the hindwing beneath gradually increases in breadth anteriorly, only close to the costal margin it again becomes somewhat narrower, the anterior eye-spot is placed in this band, the 2nd on the boundary between band and marginal area. From the province of St. Catharina (Brazil). — A hitherto undescribed form of *rectifascia* with simple markings I call **servius** (46 c). It is considerably smaller (expanse 53 mm), the teeth at the margin of the hindwing are much less prominent, so that it is similar in form to the smaller *Taygetis*-species *kerea* and *penelea*, but the straight, brownish white median band on the underside of the hindwing, which is 11½ mm in breadth, is placed as in *rectifascia*, and as in the latter is sharply defined proximally, but not distally. Instead of the small ocelli there are white dots on both wings, only the last dot on the hindwing is surrounded by a black ring. For the rest the ground-colour of the under surface is unicolorous grey-brown with very indistinct dark brown marbling at the margins and dark brown marginal double lines. The upper surface is unicolorous dark brown like the type-form. From the province of Minas Geraës (Brazil).

T. nymphea Btlr. Shape as in *ypthima*. The hindwing somewhat less strongly dentate. Upper surface olive-brown, somewhat reddish at the margin, with blackish submarginal line. The under surface resembles *virgilia* in the markings, the second transverse line running almost entirely straight on both wings and only forming a small angle on the hindwing at vein 2. But the submarginal line is much more strongly dentate, there being 2 teeth in each cellule. The ground-colour is mixed with rose-red, paler in the ♀, the border is darker as far as the submarginal line. Before this are placed on a lighter ground on the forewing 4 ocelli, on the hindwing 5. They consist of fine brown rings, measuring 2—4 mm., with dark dots in the middle, some of which have white centres. The third and fourth ocelli on the hindwing are larger than the others. Honduras, Nicaragua, Guatemala.

T. virgilia Cr. (= *rebecca* F.) (45 a). Forewing not projecting at the apex, margin of the hindwing even in the anterior half, undulate in the posterior half, only at vein 4 with an obtuse point. Upper surface unicolorous brown. Under surface brownish grey with 2 straight, parallel, brown transverse lines, a short brown streak on the discocellular of each wing and a fine dentate submarginal line, before which are placed on the forewing 5 white dots and on the hindwing 6. At the distal margin the ground-colour shades off into brown. A widely distributed and common species. Mexico, Guatemala, Nicaragua, Costa Rica, Panama, Colombia, Guiana to South Brazil (Rio de Janeiro and Joinville). — **rufomarginata** Stgr. (46 a) is a form which occurs in both sexes amongst true *virgilia* in both north and south. It may be recognized by the reddish brown distal margin, 3—4 mm in breadth, of the posterior half of the hindwing above. In addition the under surface is more reddish brown. The larva of this form was bred by SCHMALZ at Joinville. It is green with yellow longitudinal stripes, with a small rolled-up forked tail. The whole larva with fine hairs. It lives on bamboo. The pupa is green, oval, hanging free. The pupal stage lasted 18 days. The butterfly flies at the beginning of December. — **erubescens** Btlr. (46 b), a further form of *virgilia*, is above unicolorous brown, beneath reddish pink, at the inner margin of the forewing olive-brown, the base of the hindwing rust-coloured, with a dark rust-brown median band through both wings, a large oval rust-coloured spot at the end of the cell of the forewing and a similar spot in the cell of the hindwing. From Colombia (Rio Dagua, Bogotá).

T. chrysogone Dbl.-Hew. (45 a) is a large species of 80—90 mm. expanse. The shape of the wings is similar to that of *virgilia*, but the hindwing has sharp angles on veins 1 b to 4, especially the tooth on vein 4 projects more strongly than the others. The whole margin of the hindwing is bordered by a broad,

brownish ochre-yellow band, which is proximally strongly dentate and extends from the apex to the inner angle. Under surface light reddish brown with 2 straight parallel brown transverse lines through both wings as in *virgilia*. At the distal side of the 2nd transverse line a whitish nebulous stripe. In the marginal area a row of white dots in indistinct rings and a brown dentate line. From Colombia (Bogotá, Carmen), Venezuela, and Peru. According to FASSL the egg is almost twice as large as that of *Pap. machaon*, white, spherical and completely covered with fine pores like a *Corades*-egg.

acuta. **T. acuta** *spec. nov.* (45 b) approaches *virgilia* in the markings, but the shape is different. The forewing is much longer at the costal margin, the hindwing at the inner margin, whilst the inner margin of the forewing and the costal margin of the hindwing are the same length as in *virgilia*. The distal margin of the forewing is consequently much more oblique. Vein 1 b (the submedian) of the hindwing runs out into a sharply projecting point. The point at vein 4 is even sharper. On the other hand the margin does not project at the other veins, but is only slightly undulate. Upper surface unicolorous brown. Under surface yellowish grey-brown with 2 straight brown lines as in *virgilia*, but the outer line runs more parallel with the distal margin. At the costal margin of the forewing it is 11, at the inner margin 9 mm. from the margin, whilst the distance in *virgilia* amounts to 14 and 7 mm. On the hindwing also this line runs for the most part parallel with the distal margin. From Espirito Santo (Brazil).

celia. **T. celia** *Cr.* (45 a). The distal margin of the forewing forms an obtuse angle on vein 5. The hindwing is dentate not only in the posterior half but also in the anterior, the tooth at vein 4 is stronger than the others. Upper surface unicolorous brown. Under surface yellowish grey-brown, on the hindwing with a somewhat violet tone, with 3 strongly curved brown stripes and the distal margin partly brown. On the third stripe are placed on each wing 5 dark brown eye-spots with white pupils and brown-yellow rings.

keneza. From Surinam, Brazil, Panama (Veragua). — **keneza** *Btlr.* (45 b) is a form of *celia*, which only differs in the less prominent eye-spots and an ochre-yellow spot on the middle of the hindwing beneath. From Nicaragua, *haenschi*. Panama, Colombia, Ecuador, Guiana; Brazil (St. Catharina). — **haenschi** *form. nov.* (45 b) is a considerably larger form of *celia*, expanse ♂ 71 mm., ♀ 85 mm. The wings with more strongly produced apex. Above brown, the fringes between the veins whitish. On the underside the median band of the hindwing is almost straight and distally sharply bounded by a dark brown line. The distal margin of both wings is in the ♂ broadly bordered with dark brown, in the ♀ on the other hand the whole under surface is lighter grey-brown and only the boundary-line of the bands dark brown. Hence the dark brown rings of the eye-spots stand out more distinctly in the ♀ than in the ♂. The pupil of the ocellus in cellule 2 of the hindwing is much larger than the others. Collected in Bolivia by HAENSCH and named in his honour. Colombia (Rio Vitaco).

uncinata. **T. uncinata** *Weym.* (45 b) has the shape and size of *celia* *Cr.*. Above brown with dark brown distal margin about 3 mm broad, white-grey for 1 mm. at the extreme edge, ciliae likewise white-grey. The under surface is characteristically marked in that from the dark brown median band of the forewing, which is 8 mm broad and separates the bluish grey basal half from the yellowish grey marginal area, a pointed tooth projects distally on vein 4, dividing the lighter part of the marginal area into 2 parts. On the hindwing the brown median band is removed further distad, so that it closely approaches the eye-spots. From Mexico. The species seems to be rare.

angulosa. **T. angulosa** *Weym.* (45 b). This is an isolated species as regards shape and markings. The distal margin of the forewing is ventricose in the middle, that of the hindwing forms a rectangular tooth on vein 4, but has no other sharp angles. Expanse 68 mm. Upper surface grey-brown, at $\frac{2}{3}$ the length of the wing is placed at the costal margin of the forewing a distally and posteriorly curved yellow-grey stripe, which only reaches to cellule 3. Hindwing with a dark brown submarginal line. Under surface yellowish grey, dotted with brownish, the veins darker. The transverse lines fine, dark brown. The anterior transverse line extends on both wings through the cell to the median. On the hindwing it is continued to the inner margin. The 2nd transverse line forms on the forewing a W, the points of which are placed on veins 3 and 4, on the hindwing it forms a right angle on vein 4. In the marginal area 3 white dots on the forewing and 5 on the hindwing; then follows a thin dentate submarginal line. Brazil (Amazonas, Petropolis). Rare.

andromeda. **T. andromeda** *Cr.* (= *laches* *F.*, *fatua* *Hbn.*). Expanse 68—83 mm. The distal margin of the forewing in the ♂ produced into a somewhat obtuse angle at veins 5 and 6, in the ♀ this angle is not present, the margin being uniformly rounded here. Hindwing in ♂ and ♀ uniformly angled at all the veins. Above unicolorous brown, the lighter band of the under surface in the ♀ showing through faintly above. Under surface bluish grey, with a rather broad basal band and a very broad, dark brown median band. The latter is distally straight and sharply defined, and is followed by a straight, whitish grey band extending from the costal margin of the forewing to the hindmargin of the hindwing. Beside this are placed in the marginal area on the forewing 5, on the hindwing 6 yellow-brown ocelli with ochre-yellow and brown rings and white pupils, only the 5th ocellus on each wing is brown or black. From Mexico, Guatemala, Nicaragua, Costa Rica, Panama, Colombia, Venezuela, Peru, Guiana, the Amazon to South Brazil (Rio de Janeiro, São Paulo) and Paraguay.

— **thamyra** Cr. (45 c) is a form of *andromeda* in which the eye-spot in cellule 2 on each wing is not black but *thamyra*, coloured like the others. From Surinam. — **marginata** Stgr. differs from true *andromeda* only in having *marginata*, the extreme border of both wings grey for a breadth of about 1 mm in addition to the grey fringes. It occurs in South Brazil (province of São Paulo) and in Paraguay. — **leuctra** Btlr. (45 c) is also referred to *andromeda* by GODMAN and SALVIN. The median area of both wings is broadly dark brown beneath, proximally shading off into lighter, distally sharply bounded by a straight white band. Behind this in the marginal area are placed on a white ground on the forewing 5 small ocelli, on the hindwing 4 somewhat larger ones, of which the 2nd and 5th on the forewing and the 1st and 4th on the hindwing are black, the others brownish, but all have yellow rings and white pupils. Sometimes (as in the example figured) there is in addition a small 5th ocellus on the hindwing. Rare. BUTLER knew no locality, the example figured is from Terapato in Peru. — **uzza** Btlr., a further form of *andromeda*, in which on the dark brown upper surface of the forewing 2 ochre-yellow bands are placed, one behind the middle, the other before the margin, the latter being proximally margined with brown. On the under surface the basal area is light bluish grey to the middle of both wings, where it gradually shades off into the narrow dark brown median band. The latter is distally not quite straight, but sharply defined. Next to it is placed the white-yellow band of the marginal area, and then follows the almost ochre-yellow marginal area, which is only bluish grey in the inner-marginal half of the hindwing, with 6 eye-spots on each wing, of which only the two last on the hindwing are black with red-yellow rings, all the others being ochre-yellow. Described by BUTLER from a ♀ from St. Geronimo in Guatemala, coll. SALVIN. — **elegia** Stgr. i. l. (45 c) is a hitherto undescribed form of *andromeda*, which most nearly approaches *uzza* Btlr. Instead of the two ochre-yellow bands of *uzza*, *elegia* has only one, which extends from the costal margin of the forewing to beyond vein 2 and decreases uniformly in breadth from 11 mm anteriorly to 4 mm posteriorly. The hindwing has sharp angles at all the veins and is unicolorous dark brown with a fine darker submarginal line. The under surface is similar to that of *andromeda*, basal and median area of both wings dark, the proximal part of the marginal area of the forewing is dull ochre-yellow like the upper surface, the 2nd eye-spot is removed somewhat distad as in *andromeda*. The hindwing has behind the middle a light lilac straight band, of the 6 ocelli the fifth is not darker than the others, but of the same colour. ♂ from the Rio Songo (1200 m) and Yungas, Bolivia. Coll. BANG-HAAS. — I give the name **asterie** to a new form of *andromeda* in which the marginal area on the underside of the forewing is only a little broader at the costal than at the inner margin, namely 14 mm. against 12. The light band in the proximal part of the marginal area, which is ochre-yellow and 4 mm. in breadth, is consequently much more vertical and is continued in the same direction on the hindwing. The rest of the marginal area is brownish ochre-yellow, on the forewing with five ocelli, on the hindwing with six, of which the first on the forewing and the first and last on the hindwing are only small, the others with the exception of the one in cellule 2 all measure 3 mm. in diameter, but that in cellule 2 has a diameter of 6 mm. and hence immediately attracts attention by its size, moreover it is deep black and has an ochre-yellow and a brown ring and thick white pupil. The other ocelli are all yellow-brown with ochre-yellow and brown rings. The light band of the underside shows through somewhat on the otherwise unicolorous brown upper surface. From Colombia (♀: coll. WEYMER). — **cleopatra** Fldr. (45 c) should probably also be regarded as a form of *andromeda*, although the light under surface and the often very indistinct eye-spots give it the appearance of an independent species. The upperside is brown, the ground-colour of the underside everywhere light lilac. The lightest examples have the transverse bands between basal and central areas and between central and marginal areas only narrow, but the latter transverse band is usually the broader, so that it fills up the distal half of the median area with brown; on the forewing, however, the whole of the median area is often brown, at least in its anterior half. The distal half of the marginal area is likewise brown and shades off proximally on both wings into the lilac ground-colour. Here are placed on the forewing five, on the hindwing six white dots in more or less distinct rings, which latter, however, are often wanting. From Brazil (Rio Negro, Bahia, Espirito Santo). In the examples from Espirito Santo the marginal area of the forewing is much narrower, measuring anteriorly only 10 mm., posteriorly only 8.

T. xenana Btlr. (46 b). Distal margin of the forewing straight, but rather oblique, the apex rounded, the hindwing feebly dentate. Upper surface unicolorous dark brown, the apex of the forewing somewhat lighter. On the under surface the base and middle of both wings are dark brown, distally bordered by a straight, light lilac line. Marginal area lighter brown with a row of five white dots on the forewing and six on the hindwing, which are indistinctly margined with ochre-yellow. From Cayenne and from Pebas in Peru. — **sosis** Hpffr. (45 d) is quite similar to the preceding in markings, but the forewing is shorter and broader and its distal margin more vertical. Moreover, the hindwing is more strongly dentate. On the underside the marginal area at the costal margin of the forewing is much narrower, and hence its proximal boundary, i. e. the light lilac, distally diffuse line, runs almost parallel with the distal margin, whilst in *xenana* it converges strongly with the distal margin. On the black-brown basal half of the hindwing beneath there is a strongly curved black transverse line. The white dots in the marginal area are very distinct. Peru, Surinam, Brazil (Espirito Santo and Bahia). — **godmani** Stgr. i. l. (46 b) is similar to *xenana*, but the forewing is narrower, more elongated and the distal margin incurved in the middle. Upper surface brown. Under surface dark brown to beyond the middle,

distally straight-edged; at the base only a little lighter, the basal area of the hindwing bordered by a straight dark transverse stripe, in the marginal area traversed throughout by a lilac transverse band, which on the forewing is anteriorly broad and posteriorly narrow, but on the hindwing on the contrary anteriorly narrow and posteriorly broad, and in which on each wing are placed 5 white dots. Of these dots the one in cellule 2 on the hindwing is surrounded by a broad black ring and a fine ochre-yellow one, which is $2\frac{1}{2}$ mm. in diameter. From Chiriqui and from the Amazon.

zippora. **T. zippora** *Btlr.* Shape and size of *godmani*. Above brown, before the apex of the forewing with a large triangular, yellow-grey spot, in the middle of the hindwing a very large, round, black spot, which extends nearly to the costal margin, but not to the distal and inner margins. On the under surface the base of both wings is black-brown, at the inner margin and distally lighter, with two black transverse lines, of which the distal one is bordered with lilac, apex of both wings dusted with lilac, an undulate submarginal line and the distal margin itself black. Forewing with five, hindwing with seven small, brown, white-centred and yellow-ringed ocelli, of which the 5th on the hindwing is larger than the others. Recognizable by the large black spot on the upperside of the hindwing. Cayenne. Rare.

echo. **T. echo** *Cr.* (= *betro Godt.*). Above brown with large, velvety, black-brown spot in the middle and a red-brown diffuse band before the apex of the forewing. Beneath the larger basal half is dark brown, the smaller distal half lighter brown, the boundary of the two colours is formed on the hindwing by a straight line, on the forewing by a somewhat curved one. In the marginal area there are five white dots on the forewing and six on the hindwing. Surinam, Cayenne, Amazons (Ega). — **velutina** *Stgr.* (46 a) is a form differing but little from *echo*, in which the velvety spot of the forewing is deeper black, but the red-brown band more indistinct. From Puerto Cabello (Venezuela) and Surinam.

banghaasi. **T. banghaasi** *spec. nov.* (45 d). Expanse 55 mm., forewing at the apex rectangular, at the distal margin rounded, somewhat ventricose. Hindwing between the veins only slightly excised. Upper surface unicolorous brown. Under surface in the basal half of both wings grey-brown with an almost straight dark brown transverse line. Before the discocellular in the cell of both wings a diffuse ochre-yellow spot. Distal half of the wings yellow-brown. A lilac-coloured band, 2—3 mm. in breadth, with washed-out margins, runs on both wings from the apex to the inner angle, on the forewing in a proximally directed curve, on the hindwing straight. At the proximal side of this band on each wing five white dots, on the forewing indistinct, on the hindwing distinct, especially the dot in cellule 2. Named in honour of Herr BANG-HAAS of Dresden. From the Rio Songo (1200 m) (Yungas), Bolivia.

puritana. **T. puritana** *Weeks.* As the author says nothing about the relationship to other species and of the shape of the wings, it is possibly not correctly placed here: Expanse 3 inches = 76 mm. Upper surface dark brown with white marginal line. Under surface much lighter brown with a broad dark band through the middle of both wings. A dark brown line crosses the middle of the cell of the forewing and extends to the inner margin. At the end of the cell a fine brown bar. Then follows the dark brown band, shading off lighter proximally, which extends from the costa to the submedian and is sharply defined distally by a dark brown line. In the light brown marginal area a dark brown, zigzag submarginal line and a row of six white dots, which are margined with brown, at the distal margin a white line. On the hindwing the dark band stands out more strongly. Its proximal margin is bounded by a dark line, which begins at the costa 8 mm. from the base and extends to the middle of the inner margin. The line which forms the distal margin of the band extends from the middle of the costal margin across the end of the cell to the inner margin, which it reaches 8 mm before the anal angle. The marginal area is as on the forewing, but only five white dots are present, which, however, stand out more distinctly. Bolivia (Coroico).

salvini. **T. salvini** *Stgr.* (45 d). Above unicolorous brown, the hindwing in this and the two following species shortly but uniformly angled on veins 1 b to 4. Under surface reddish grey-brown, the first transverse line on both wings a little curved distad, dark brown, the distal half of the median area broadly filled up with dark brown and straight-edged, the marginal area broader anteriorly than posteriorly, its proximal half lilac. Each wing with five ocelli, the last on the hindwing filled in with black, the others yellow-brown, all with white pupils. Colombia, Panama (Chiriqui).

tripunctata. **T. tripunctata** *Weym.* (45 d). Above brown with three white spots in a straight row one below another on the forewing, the light band of the underside shows through somewhat above on the hindwing. Under surface lighter brown with narrow, almost straight, distally diffuse white band scarcely 1 mm. in breadth across both wings, and five white, brownish-margined spots on each wing, as well as a finely dentate submarginal line. The marginal area of the forewing is equally broad anteriorly and posteriorly. From Puerto Bertoni and Nuova Germania (Paraguay).

sylvia. **T. sylvia** *Bates* (= *nymphosa Btlr.*) (45 d) is referred by GODMAN and SALVIN in the *Biologia* to *an-*

dromeda, but it is remarked at the same time that it is the most aberrant form, differing not only in the markings but also in the shape. On account of the white band on the under surface, which on the forewing runs parallel with the distal margin, in consequence of which the marginal area is equally broad anteriorly and posteriorly (in *andromeda* this is not the case), I regard *sylvia* as a good species and place it between *tripunctata* and *blanda*. The upper surface is unicolorous brown. On the under surface basal and median areas are uniform light brown, only the distal part of the median area somewhat darker. The first transverse line is dark brown, not quite straight. The straight white band which follows is narrow on the forewing, on the hindwing it gradually attains the width of 3 mm. In the light brown marginal area are placed on the forewing five, on the hindwing six small eye-spots, of which the 2nd and 5th on the hindwing have black rings and the others brownish ones, but all have white pupils. From Panama, Upper Amazon and Bolivia. — **blanda** Möschl. (45d) is *blanda*. similar to the preceding, but the inner angle of the hindwing more rounded. Upper surface unicolorous brown. On the under surface the white band is broader and on the hindwing somewhat curved. The ocelli somewhat larger, the posterior one on the forewing indistinct, on the hindwing entirely absent. The 2nd and 5th on the latter wing surrounded with thick black, then ochre-yellow and brown rings, the others ringed with grey and brownish. From Surinam and Peru (Cuzco).

T. albinotata Btlr. (46b). A beautiful species. Forewing with the margin entire, hindwing with rounded projections on the veins. Upper surface brown, the forewing either unicolorous or with six small, pale brown, indistinct spots before the margin. Hindwing somewhat darker at the margin, before this four round white spots in a straight row and a 5th dot at the inner angle. The fringes white between the teeth. Under surface lighter brown with three whitish yellow transverse stripes on each wing, between the 2nd and 3rd of these stripes on the forewing before the apex 1—3 small ocelli, on the hindwing six large ocelli, the middle ones reddish grey, the others black, all yellow-ringed and with white pupils. From Bolivia, South Peru and Ecuador. Rare.

T. penelea Cr. (45e). Above brown with a broad, somewhat lighter submarginal band on the forewing, in which are placed 3—4 dark brown spots. On the under surface a light yellow longitudinal band traverses the middle of the hindwing from the base to the distal margin. In the broad, light reddish grey submarginal band are placed on the forewing 2—5, on the hindwing 4—5 dark eye-spots, some large and some small, which have yellow rings and white pupils. Widely distributed and common. Panama, Venezuela, Colombia, Surinam, Cayenne, Amazon region to South Brazil (province of St. Catharina). — **penelina** Stgr. is a form of *penelea* in which the light yellow band of the underside is absent, being covered over by the grey ground-colour. Moreover, at the costal margin of the hindwing there are 2 large black-brown spots, which entirely or partially cover the anterior ocelli of the type-form. In the eye-spots which are still present the pupils have mostly disappeared. From St. Catharina.

T. valentina Cr. (= *Debis marpessa* Hew.) (45e). Above dark brown; beneath lighter brown with three very dentate, thin dark brown transverse lines, the space between the second and third proximally light violet-grey, distally filled up with white-grey and with 5 ocelli on each wing, of which the two anterior ones and the last on the hindwing are darker than the rest. Beside the first and second transverse lines there are small ochre-yellow spots in the cell of the hindwing. Guatemala, Nicaragua, Guiana, Amazons. — **euptychidia** Btlr. (45e) is a form of *valentina* in which the ground-colour of the underside is much lighter, the dentate brown transverse lines are very faint and of the eye-spots only 1 or 2 on the forewing and 2 or 3 on the hindwing are distinct, the others indistinct or replaced by white dots with somewhat darker margins. From Brazil (Pará, Espírito Santo). — **zimri** Btlr., referred by GODMAN and SALVIN to *valentina*, is a somewhat larger form, which differs from *valentina* in that the forewing has an obtusely projecting angle on the distal margin below the apex, the eye-spots of the forewing are not some dark and some light, but all uniformly yellow-brown and hence stand out but little from the violet-brownish ground-colour, and there are 6 eye-spots on each wing. For the rest the transverse lines are quite as dentate as in *valentina*. From Chuacus in Guatemala. — **vrazi** Kheil, a further form of *valentina*, in which the distal margin of the forewing is very feebly dentate, that of the hindwing more strongly so, the eye-spots of the hindwing are larger and more sharply marked, the ochre-yellow spot at the first transverse line is absent, but this varies also in *valentina*. Rio Atabapo (Venezuela) and Rio Negro (Brazil).

T. kerea Btlr. (45e). One of the smallest species (48—50 mm. expanse). The distal margin of the forewing rounded, the hindwing feebly dentate. Above brown with 2 dark lines at the distal margin and a whitish line between them; the latter stands out most distinctly in the angles of the hindwing. In addition a thin brown submarginal line. Beneath yellowish brown with 3 fine dark brown transverse lines; the first on the forewing indistinct, on the hindwing dentate, the second on the forewing almost straight, on the hindwing running parallel with the distal margin in one long curve, the third as a submarginal line forming short, small curves. In addition 2 fine brown marginal lines with a lighter line between them. Behind the second trans-

verse line 5 white, dark-margined dots on the hindwing and 3—5 more or less indistinct smaller dots on the forewing. Guatemala, Brazil (Espirito Santo), Paraguay.

inornata. **T. inornata** *Fldr.* (46 c). Above brown with 2 darker lines at the distal margin. Under surface lighter with 2 brown lines through the middle of both wings, which on the forewing diverge towards the costal margin, the proximal one forming a curve in the cell, the distal one almost straight; on the hindwing the proximal line is almost straight, while the distal one is curved outwards at the costal margin and forms 2 shallow curves in the middle. At the distal margin 3 brown lines, of which on the forewing the proximal one is undulate and the distal two straight, but on the hindwing all three are undulate. Three white dots on the forewing before the apex, the two lower ones very small, five white dots on the hindwing in cellules 2—6. Colombia (Bogotá).

10. Genus: **Amphidecta** *Btlr.*

Forewing at the distal margin with an obtuse angle below the apex, costal and median much inflated at the base, hindwing with the costal margin fairly straight, the inner margin much longer than the costal, distinctly emarginate, the distal margin dentate, the precostal vein distinctly forked, otherwise the neuration as in *Taygetis*; antennae thin, with scarcely appreciably thickened clubs. Eyes naked; the palpi projecting beyond the head, flattened at the sides, the hairs forming a sharp crest beneath. The genotype is *pignerator*. The two species united with it here differ somewhat in the shape of the forewing, the obtuse angle at the distal margin not being present, but the elongated inner margin of the hindwing and the scheme of markings of the forewing point to a relationship with *pignerator*. The butterflies are of less than medium size, and have been taken at isolated places in Central and South America, but as yet are little distributed in collections.

pignerator. **A. pignerator** *Btlr.* (46 c). Expanse 62 mm. Above grey-brown, on the forewing with 3 round white spots, which are placed in a triangle, one between median veins 1 and 2 and two between median 3 and the lower radial. The hindwing without markings; the marginal line on both wings dark brown, the fringes between the veins whitish. Forewing beneath light grey, the distal part from the apex to nearly the middle of the costal margin and to the inner angle, and also the costal margin itself to the subcostal are finely sprinkled with dark brown, in which colour in addition to the 3 white spots of the upper surface there is a fourth narrow white one and beside it a dark brown spot. Hindwing beneath lilac, sprinkled with violet all over, with 3 dentate transverse bands composed of brown dots, one before, the second behind the middle, the third before the distal margin. Before the latter a row of black dots in light rings. The species appears, however, to be very variable in the colour and markings of the hindwing beneath, as recent consignments from Herr FASSL prove. An example captured at Villavicencio has the underside of the hindwing light brownish grey with a brown distal margin 3—4 mm broad and not sharply defined. The under surface is sparsely adorned with small, fine brown striae, but in such a way that no dark transverse bands are formed, the striation being uniformly distributed all over. The transverse row of fine black dots just before the brown distal margin is, however, distinctly present. The species is but little represented in collections as yet. BATES found it many years ago at Ega on the Amazon in the dense primeval forests, FASSL quite recently at Villavicencio in East Colombia (450 m.) in April. — I give the name **simplicia** *form. nov.* (46 c) to a form of *pignerator* which is dark earth-brown above and has 4 white spots in the apical part of the forewing, which is black with a very dull blue reflection. From Minas Geraës (Brazil).

reinoldsi. **A. reinoldsi** *spec. nov.* (46 c). Expanse 48—50 mm. Above olive-brown, distal half of the forewing dark brown with 8 white spots, which are placed in two rows proximally curved in the middle. At the distal margin of the hindwing a double dark brown undulate line. Under surface grey-brown, the 8 white spots as above and placed in a brown area, which is surrounded by the ground-colour at the costal and distal margins. The hindwing has somewhat before the middle a straight dull white band, then a curved row of round ochre-yellow spots, each of these with a black dot or short streak in the middle. Before the margin a dark brown dentate line, which bears a black dot in the middle of each cellule, and two undulate lines close to the distal margin. The ♀ has a somewhat lighter, more yellowish ground-colour. On the underside of the hindwing the yellow spots are so widened that a continuous band is formed, in which besides the black dots and striae some shiny silver scales are strewn. Minas Geraës, St. Catharina (Brazil). Rare.

calliomma. **A. calliomma** *Fldr.* (46 b). 62 mm. Upper surface olive-brown, the distal third of the forewing darker, with two distally curved rows of 5 brownish white spots each, of which the anterior ones are somewhat indistinct. Hindwing with a submarginal row of brown spots. On the underside the forewing is as above, only somewhat lighter. The hindwing is marbled with dark brown on a grey-brown ground, with 2 silver spots, one near the base, the other in the middle. Behind the latter 3 dark brown eye-spots in ochre-yellow rings, with shining silvery pupils, of which the posterior one is the most distinct. From Colombia (Cordillera of Bogotá, Villavicencio, 750 m., May), Amazon (Manaos). Rare.

11. Genus: **Euptychia** Hbn.

This extensive genus with its numerous forms is by no means exactly defined as to its limits, as certain species form a complete transition to the genus *Taygetis*. In general all the butterflies are small to medium sized, only a few species reach a wing-expanse of nearly 6 cm., most remaining below 4 cm. The principal characters of the genus are the hairy eyes, the strongly inflated costal and median at the base, and the somewhat inflated submedian of the forewing. The short, distally curved precostal of the hindwing mostly arises before the subcostal. The upper discocellular of the hindwing varies in length. The forelegs of the ♂ are weak and long-haired. The wings are mostly rounded, the forewing has the apex rounded and little produced, its distal margin is almost straight, that of the hindwing is mostly undulate, sometimes completely round, in other species more strongly dentate, the inner margin of this wing is sometimes somewhat emarginate. But general distinctive characters are furnished by the stripes and the row of eye-spots on the underside of both wings. Only a few species have dots instead of the eye-spots. In the greater part of the Euptychias the colouring is brown or grey-brown. There are, however, also many which are distinguished by a brilliant light blue colouring and which when flying might be taken for Lycaenids. Others have a bright blue reflection on both wings or a part of them, others again have the ground-colour white. Of the eye-spots the one between medians 1 and 2 on the hindwing is mostly present and also usually larger than the other ocelli. Next to it the eye-spot between the two radials of the hindwing is the most developed. If one or several eye-spots are present on the forewing, one of them is likewise placed between the two radials.

The greater number of the species occur in tropical South America. Single species extend southwards to South Brazil and Argentina; from Chile, however, no species is yet known. To the north the genus reaches the limit of its range in the United States. The American authors place the 7 species occurring there in the genera *Neonympha* Hbn. and *Cissia* Dbl. But as these species have exactly similar allies in Mexico and in tropical Central and South America, I follow BUTLER and GODMAN and SALVIN in referring them all to *Euptychia*. As concerns the vertical distribution of the Euptychias, Prof. BÜRGER in his „Reisen eines Naturforschers im tropischen Südamerika“ („Travels of a Naturalist in Tropical South America“) states that they only occur in the „Tierra caliente“ and „Tierra templada“, the hot and moderate zones, thus up to 2000 m. The great majority of the species will be confined to these regions, but some few ascend somewhat higher and reach the middle of the „Tierra fria“, the cold zone, as FASSL has observed the species *neceys* Godt. and *harmonia* Btlr. at the Quindiu Pass in Colombia at altitudes of 2500 m.

The habits of the Euptychias (according to Dr. SEITZ *in litt.*) are not altogether uniform. The members of the *hesione* group are tireless, although by no means swift fliers; their ♂♂ may be seen at almost all hours of the day flying straight along the edges of woods or bamboo hedges, more resembling a *Pieris* than a Satyrid. Even where they are common, as e. g. in Bahia, where they even come into the town, they are mostly met with singly; and Dr. SEITZ, who observed them there day after day, never saw them in large companies like the species of the *hermes* group. The latter are mostly dark-coloured species, show a decided preference for shade and come fluttering out from the thickets especially in the early morning hours, before the sun finds its way into the deep-cut mountain-valleys, flying low, after the manner of *Coenonympha hero*, and settling in large groups at the dew on the roads. Between 8 and 10 o'clock whole swarms of small *Euptychia* may be met with in the Botanical Gardens of Rio de Janeiro, where they rest on shady paths round the water and can scarcely be driven away, as when disturbed they only fly round and round a few times close to the ground, settling again in the same place after a few seconds. The larger forms of the *celmis* group are more retiring, carefully avoiding open paths and clearings, which they cross but rarely and with evident uneasiness; but they resemble the *hermes*-like forms in their habit of closing the wings spasmodically when resting, much as the European *Aphantopus*, from which in the same locality they can only with difficulty be certainly distinguished when flying. The larger species, of which some are also obviously nearly allied to *Taygetis*, show themselves more commonly in open places, the lilac gloss of their upper surface glittering in the sun, which the darker species carefully avoid. Finally the sky-blue species of the *cephus* group are especially lively in bright weather and contribute, together with other insects, to the wealth of bright blue colour which is a feature of the larger forest-clearings of tropical America, competing with *Thecla*, *Morpho*, *Pythonides*, glossy blue dragon-flies, Hymenoptera, bugs and beetles in the brilliancy of their blue and metallic scaling.

Concerning the earlier stages of the Euptychias little is known. Of some North American species EDWARDS has furnished descriptions and figures of the eggs, larvae and pupae; on the other hand MÜLLER, who obtained eggs and small larvae of some Brazilian species, was not able to bring any as far as the first moult. They live on grasses.

It is not within the scope of this work to give a monographic working out of the genus; we only offer a survey of those already known, and in this we chiefly follow the work of BUTLER with some few modifications. The types of FELDER's species, which BUTLER was not able to make out, we here figure above and beneath, but must merely refer at the end to some species described and not figured by other authors, as in these cases similar or allied species are not mentioned.

Hesione Group.

- hesione*. **E. hesione** Sulz. (= *ocirrhoe* F., *cissia* Cr.) (46 d). Above white with broad black apex to the forewing, which is more or less continued on the distal margin. In the ♀ the margin of the hindwing is also black and the forewing has a dark median band. On the under surface brown and white transverse stripes alternate, before the distal margin are placed on the forewing 3, on the hindwing 5 ocelli. The extent of the black colour on the upper surface varies very much according to the locality. Widely distributed and common. Mexico, Central America, Surinam, Colombia, Peru, Bolivia, Brazil as far as St. Catharina. The examples from Bolivia
- subobscura*. have the forewing somewhat more pointed, otherwise I see no difference. **subobscura** form. nov. (46 d) is an aberrant form, in which the white bands of the under surface, except the distal one, are covered by a brownish grey
- lydia*. colour. I have received this from Paraguay, but it also occurs at single localities in Brazil. — **lydia** Cr. is a somewhat larger form (60 mm.) with broad, rounded wings. Forewing almost entirely brown, only the basal half of the inner margin is dusted with white, but indistinctly defined. The hindwing is white with 3 fine brown marginal lines and 2 round black spots in cellules 2 and 5. On the under surface the brown bands are much narrower in the basal area, the white bands on the other hand twice as broad. Forewing with 2,
- calpurnia*. hindwing with 5 eye-spots, similar to those of the type-form. Surinam. — **calpurnia** Fldr. (46 d) is a form similar to *lydia*, but somewhat smaller (50 mm.), with somewhat narrower and more elongate forewing, which has a very shallow excision at the distal margin. The brown ground-colour is somewhat lighter than in *lydia*, the white extends on the forewing from the inner margin to the median, the brown stripes of the under surface show through above on both wings, and also the eye-spots, of which, however, only one is present on the forewing
- binocula*. and only 3 on the hindwing. From the Maroni in Cayenne, Surinam. — **binocula** Btlr. (46 d), a further form of *hesione*, has the upper surface of both wings light grey-brown with 2 dark brown bands through the middle and broad brown distal margin, which occupies over a third of the wings, only the middle of the hindwing is dull white and in cellule 2 there is a round black, white-bordered spot. The under surface is as in *hesione*. From Cayenne.
- metaleuca*. **E. metaleuca** Bdv. (= *butleri* Dist.) (46 d) is indeed nearly allied to *hesione* Sulz., but following the example of GODMAN and SALVIN I regard it as a good, independent species. Whilst in *hesione* and its allies the light bands on the under surface are all nearly equal in breadth, in this species the distal band is more than twice as broad as the others, moreover these narrower, basal bands are mostly strongly dusted with grey-brown. In addition the forewing of the ♂ is not so round, but more triangular and at the distal margin somewhat waved. The upper surface of the forewing is black-brown, with a white triangle on the middle of the inner margin. From Mexico, Brit. Honduras, Guatemala, Nicaragua, Costa Rica, Panama, Colombia, Ecuador. —
- languida*. **languida** Btlr. (46 e) is a form of *metaleuca*, in which the white colour is reduced on the forewing but somewhat extended on the hindwing, and in the middle of the distal margin reaches nearly to the border. In cellule 2 and in cellule 5 a black, eye-shaped spot is placed on the dark border. The under surface is grey-brown with broad white median band, an eye-spot on the forewing in cellule 5, 3 eye-spots on the hindwing in cellules 2, 5 and 6, all black with yellow rings and white pupils. Between the eye-spots of the hindwing and below the eye-spot of the forewing are placed some small round silvery spots. Columbia, Bolivia.
- hemileuca*. **E. hemileuca** Stgr., only known in the ♀, has an expanse of 38 mm. and somewhat resembles *languida* Btlr. above; but the white colour is extended nearly to the costal margin of the forewing and covers the entire hindwing, leaving only a narrow black distal margin, and the two round black spots are isolated. The under surface is entirely brown-grey with 2 narrow dark brown transverse stripes through the middle, bordered with light grey, 3 fine brown marginal lines, 1 eye-spot on the forewing and 3 on the hindwing. The anterior eye-spot on the latter is 4 mm. in diameter, with black centre and white double pupil. The others are smaller, but similarly coloured. From the Rio San Juan in West Colombia. Rare.
- aurigera*. **E. aurigera** Stgr. i. l. (46 e) resembles no other *Euptychia*; ground-colour white; on the forewing the costal margin, apex and distal margin broadly black-brown, broadest before the apex, hindwing with narrow, dentate brown border. The pattern of the under surface shows through above. This brown with a white band through the middle of both wings, extending from the lower radial of the forewing to the inner margin of the hindwing and pointed at both ends. On the hindwing are placed on a reddish ochre-yellow ground 5 ocelli in a zigzag row and between the 3 brown marginal lines small white double dots on the veins. From Cuzco in Peru, coll. BANG-HAAS. Rare.

Mollina Group.

E. mollina Hbn. (46 e). Above with the forewing whitish grey, at the costal and distal margin darker with 3 brownish transverse stripes, before the apex a dark spot. Hindwing white with 2 round dark spots in brown rings. On the under surface the ground-colour is purer white, the transverse stripes consequently more distinct. On the forewing a black eye-spot before the apex, surrounded by a brown ring, 3 indistinct eye-spots below it in cellules 2—4. Hindwing beneath with 6 eye-spots, those in cellules 2 and 5 large, in cellules 1 b and 6 small, all black with white pupils and brown rings, those in cellules 3 and 4 obsolescent. From the Amazon region (Pará, Ega), Nicaragua, Mexico. **mollis** Stgr. is only a form of *mollina*, in which the forewing has only one or two ocelli on the under surface and also those of the hindwing are reduced in number and some of them much smaller. From Chiriqui. — **hilara** Fldr. (46 e). One of the larger forms of *mollina*, above light brownish grey with one transverse stripe on the forewing and 2 on the hindwing, which are somewhat darker, with one eye-spot on the forewing and 2 on the hindwing. On the under surface the ground-colour is still lighter, somewhat whitish, the transverse stripes as above, in the median area of the forewing a reddish yellow washed-out spot and before the apex an eye-spot. On the hindwing 4 small ocelli and 1 large one. Colombia (Bogotá). — **westwoodii** Btlr. (46 e), a further form of *mollina*, mostly smaller (26—33 mm.) and with the ground-colour purer white. Only the costal and distal margins of the forewing are brownish grey. The brownish bands are narrow and the eye-spots indistinct. On the under surface the forewing has only 3, the hindwing all the 6 ocelli. Mexico, Guatemala, Honduras, Nicaragua, Costa Rica, Panama, Venezuela, Colombia, Bolivia. — **jesia** Btlr. (46 e) only differs from *westwoodii* in having the brown transverse stripes on the upper surface entirely absent or only faintly showing through from beneath, the apex of the forewing only 4 mm. in breadth and the costal and distal margins only quite narrowly brown. The under surface is as in *westwoodii*. Bolivia, Ecuador.

E. meta spec. nov. (46 e). Above grey-brown, on each wing a large white area, which on the forewing is placed nearer to the inner, on the hindwing to the costal margin. The first two transverse stripes converge anteriorly on the forewing, posteriorly on the hindwing. On the forewing a dark spot before the apex, on the hindwing three in place of the ocelli, behind them the dark submarginal band. On the under surface there is in addition a fourth band near the base of the wings and on the forewing are placed 2 ocelli near the apex and on the hindwing 3 in cellules 2, 3 and 5, all black with white pupils and surrounded by 4 rings, namely ochre-yellow, brown, white and outside again brown. The 2nd eye-spot of the forewing and the middle one of the hindwing are smaller, the others are larger, being 3 mm. in diameter and extending over two cellules, so that their outer rings touch one another. In the ♀ an additional small eye-spot is present on each wing, which is placed between the others. From Marcapata (Peru).

E. fetna Btlr. Above pale brown, forewing with 2 curved rust-coloured stripes before and in the middle, an obscure rust-coloured spot between medians 1 and 2, before the apex a round black spot in an ochre-yellow ring. Hindwing with rust-coloured median and submarginal stripes and a black eye-spot with white pupil and yellow ring. Beneath lighter, especially in the distal part of the forewing, with a chain of small brown rings before the distal margin of both wings. Forewing with a proximally curved median and a straight rust-coloured basal stripe, which are both continued fairly straight on the hindwing. The latter has 5 eye-spots, of which the 2nd and 5th are black, with yellow iris and brown ring, the others are dull red-brown, all have shining white pupils. On the forewing only one eye-spot as above, with some brownish spots below it. 36 mm. From San Geronimo and Cubilquitz in Guatemala, Amula and Chilpancingo in Mexico. Rare.

E. enyo Btlr. Above pale brown with 2 brown median stripes and a submarginal one, a marginal line, a spot before the apex of the forewing and another at the anal angle of the hindwing. The apex of the hindwing is reddish. Beneath ochre-yellow with red-brown bands as in *mollina*. Forewing with 4, hindwing with 6 ocelli. The first on the forewing and the 2nd and 5th on the hindwing are larger than the others. The 6th eye-spot on the hindwing is placed close to the distal margin and the border of cellule 1c near a red-brown longitudinal stripe characteristic of this species, which extends inwards along the first median. 35 mm. From Cuenza (Ecuador). Rare.

E. anaclela Btlr. Pale brown, 2 dark bands through the middle, a blind eye-spot before the apex of the forewing and 5 on the hindwing, the 5th being larger than the others. The submarginal line on the hindwing double. Beneath very light grey, almost white, with 2 red-brown bands in the basal half, a third, broader band, which is only red-brown on the hindwing, but ochre-yellow on the forewing, then 2 undulate blackish submarginal lines, which at the anal angle of the hindwing terminate in 2 orange-coloured streaks. Forewing with a large subapical eye-spot with blue pupil and red-yellow ring, below it 2 indistinct eye-spots and a large washed-out ochre-yellow spot. Hindwing with 5 ocelli, the 1st, 2nd and 5th black with blue pupils, the 3rd and 4th brown with silvery pupils, all with yellow iris. These ocelli, of which the 4 anterior ones are small but the 5th large, are placed in a straight row. 33 mm. Nicaragua (Chontales), Panama (Chiriqui), Colombia (Bogotá). Rare.

insolata. **E. insolata** Btlr. (= *macrophthalma* Stgr.). Smoke-brown, slightly transparent, in the disc lighter, sometimes white, 2 almost parallel brown median lines and 2 indistinct submarginal lines across both wings. Forewing with an indistinct eye-spot before the apex, hindwing with 2 black, white-dotted eye-spots, one at the apex, and a larger one at the inner angle. Beneath whitish with the bands as above, the two in the middle and one at the base red-brown, and with black submarginal line. Forewing with 2 eye-spots, one before the apex, black, white-pupilled with red ring, the other indistinct, between the median veins. Hindwing with 3 eye-spots, the two anterior ones margined with red, the third very large, with brown border, at the anal angle. From Nicaragua, Costa Rica and Panama.

picea. **E. picea** Btlr. (46 e). Similar to the preceding species, but the wings are not transparent, above brown with 4 dark brown bands, a short one at the base, the 2nd approaching the 3rd at the costal margin of the forewing, the 3rd approaching the 4th at the inner margin of the same wing. A black spot at the apex, the hindwing with 2 in cellules 2 and 5. In the ♀ the wings are more rounded and instead of the spots there are rather large ocelli with ochre-yellow rings and white pupils. Under surface light violet-grey, transverse bands more distinct than above. On the forewing are placed 2 or 3 eye-spots, of which the first is the largest, and the middle one is mostly absent. On the hindwing are placed usually 3 eye-spots, occasionally 4 or 5. Of these the one in the cell is the largest, being 3 mm. in diameter, but sometimes reaching a diameter of 4 to 4½ mm. and then naturally extending far into the adjoining cellules. Two ocelli are placed at the apex in cellules 5 and 6, of which the one in cellule 5 is about the same size as the anterior eye-spot of the forewing, the other being smaller. When additional eye-spots are present, they are placed in cellules 3 and 4, but are even smaller. From the Amazons (*rufocincta*. (Ega, Tapajos), and also from Peru and Surinam. — **rufocincta** form. nov. (46 f) is a form of *picea*, somewhat larger, the markings quite similar, but the two round black-brown spots on the upperside of the hindwing are first surrounded by an ochre-yellow, narrow ring and then by a red-brown, broad one, forming eye-spots of 4 mm. in diameter. On the under surface there are on the forewing 2 ocelli (the first large), on the hindwing 5 (the 2nd and 3rd larger), some of which are contiguous. From Surinam.

Saturnus Group.

francisca. **E. francisca** Btlr. Above violet-brown, an indistinct brown spot at the anal angle and 2 brown marginal lines. Beneath ochre-yellow, two brown, somewhat proximally curved median lines, a submarginal and 2 marginal lines. On the forewing a small eye-spot with pupil, the hindwing with 5 eye-spots, the 2nd and 5th black, with white pupils, 3 mm. in diameter, the others small, the first likewise black, the 3rd and 4th brown, all with ochre-yellow iris and brown ring. Ecuador.

saturnus. **E. saturnus** Btlr. (= *laccine* Fldr.) (46 f). Above olive-brown, with a lighter nebulous band through the middle of both wings and a black, white-pupilled and brownish-yellow-bordered eye-spot at the anal angle of the hindwing. Beneath light grey with 2 straight, brown transverse lines and a white band, increasing in breadth posteriorly, through the middle of both wings. Forewing with a black ocellus, the hindwing with 5 ocelli, of which the 3rd and 4th are brown, the others black, all with yellow iris and brown ring, the first 4 on the hindwing with double white pupil, the others with single. At the margin 3 brown lines. Venezuela, Colombia (Rio Agnata 1800 m., in November), Bolivia (Corvico), Brazil.

vesta. **E. vesta** Btlr. (= *griphe* Fldr.) (46 f). Above olive-brown, at the distal margin 3 darker lines, which are confluent on the forewing. On this wing is placed in the ♂ in the middle of cellules 1 b, 2 and 3 between the submedian and the 3 median veins a narrow streak of dark brown, raised scales, which is sharply angled distad on the veins. At the anal angle of the hindwing in cellule 2 a black eye-spot with white double pupil and red-yellow ring. Sometimes in addition a small eye-spot beside it in cellule 1c. In the ♀ the raised scales on the forewing are absent, on the other hand there are on the hindwing in cellules 3—5 two or three further similar eye-spots, which, however, are smaller, sometimes faint or without pupils. The under surface is brownish yellow with a narrow light yellow band across the forewing and a broad white band across the hindwing, irregularly defined on both surfaces, but in the middle much widened by a broad, basally directed projection. In the marginal area are placed on the forewing one, on the hindwing in the ♂ 5, in the ♀ 6 eye-spots, of which the 3rd and 4th on the hindwing are brownish grey, the others black, but all ringed with ochre-yellow and brown and bi-pupilled with white. Venezuela, Colombia (Cauca Valley, Rio Agnata, 1800 m, [November], Rio Tocha at the Quindiu Pass, 2100 m. [September]).

fida. **E. fida** spec. nov. (46 f). Similar to *vesta* Btlr., but distinguishable at once by the absence of the raised scale-streak on the forewing in the ♂. The eye-spot on the upperside of the hindwing is also absent and the light band on the under surface is differently formed. At the costal margin of the hindwing it is only half as broad as in *vesta*, it does not project basad in the cell but forms small proximal projections in cellules 2 and 5. The ♂ has beneath 6 eye-spots, the 2 middle ones brown-grey, the others black, mostly with single white pupils. On the forewing there are two indistinct smaller ocelli below the subapical one. From the Songo and Corvico in Bolivia.

E. transversa *spec. nov.* (47 a). Similar to *vesta* and *fida*. The raised scales of the former are likewise *transversa*. absent here, and there is no eye-spot on the upperside of the hindwing. Of the 3 dark brown marginal lines the inner is indistinct and more proximally directed. On the under surface are placed at the apex of the forewing 2 black ocelli with white pupils and ochre-yellow rings. The marginal area of the forewing in this species is not lighter. But the chief difference is in the underside of the hindwing. The two dark brown, dentate, narrow transverse stripes are removed further distad; the first runs behind the middle of the cell across the origin of the first median vein to the middle of the inner margin and forms in its posterior part the proximal boundary of the white band. The second brown transverse stripe runs over the closing nervure of the cell, intersecting the white band, afterwards forming its distal boundary and uniting with the dark brown submarginal line at the inner angle. Hence the anterior part of the white band is placed in this species in the much widened marginal area. In this area there are 5 ocelli, coloured like those of the forewing, the two in cellules 2 and 5 larger than the rest. From Marcapata (Peru). Rare on the Rio Vitaca (2400 m.) in Colombia.

Nossis Group.

E. nossis *Hew.* (= *jaresia* *Btlr.*). Above brown, at the anal angle of the hindwing a black eye-spot with *nossis*. red-yellow ring and white double pupil. Beneath lighter brown, forewing with 2 straight median lines, a doubly white-pupilled eye-spot before the apex and 3 brown spots below it, also 3 brown marginal lines. Hindwing with 2 brown transverse lines in the middle, the first straight, the second basally curved in the middle. Just behind these a white band traversing the wing, 3 times as broad in the middle as anteriorly and posteriorly, then a row of 4 eye-spots, of which the 2 in cellules 2 and 5 are larger, the others, in cellules 3 and 6 smaller, all black with yellow iris and brown ring, only the larger ones have double white pupils. Ecuador (Quito). This species has some resemblance to the above described *fida*, but is easily distinguished from it by the shape of the white band on the underside of the hindwing, which at its proximal side is uniformly rounded like a sector, whilst in *fida* it is strongly dentate and sinuous. BUTLER refers (*Journ. Linn. Soc. Zool.* 13, p. 117) his *jaresia* to *Eupt. furina* *Hew.* A comparison of the figures, however, shows at once that the two species are not alike, but that *jaresia* belongs rather to *nossis* *Hew.*

E. clio *Stgr. i. l.* (47 a). Forewing with the distal margin slightly undulate, hindwing obtusely dentate. *clio*. Above brown, hindwing with double dark brown marginal and indistinct, broad submarginal line, fringes light grey. Under surface likewise brown. Forewing at $\frac{3}{4}$ of its length with a narrow, straight, light grey stripe, along the distal margin a broad stripe of similar colour, traversed by 2 dark brown marginal lines. On the hindwing first a white stripe from $\frac{2}{3}$ of the costal margin to the middle of the inner margin. In the marginal area are placed 2 large brownish yellow semicircles, the curve of which is directed towards the band. Inside each a glossy silver curved line, which again encloses a large black spot with brownish yellow bordering. On the dark grey distal margin 3 black undulate lines. From Marcapata, Peru. A rare and beautiful species. Coll. BANG-HAAS.

E. albofasciata *Hew.* Size of the preceding. Above reddish brown with broad, white median band *albo-* from the 3rd median in the forewing nearly to the inner margin of the hindwing. The hindwing has a *fasciata*. large black eye-spot at the inner angle with orange-yellow ring and white pupil, as well as 2 white lines at the apex. Under surface somewhat lighter than above, the white band reaching to the costal margin of the forewing. The base is grey with a brown band, the distal margin dull white with 3 parallel brown lines. Forewing with an eye-spot at the apex, hindwing with 6 eye-spots, of which the two middle ones are oval, brown with a silver streak in the middle, the others black, in part with double pupils, but all with reddish yellow rings. From Ecuador. Rare.

Pronophila Group.

E. pronophila *Btlr.* Above olive-brown. Beneath the same, forewing with a broad, somewhat *pronophila*. lighter discal band, in which are placed 5 small indistinct ocelli. Hindwing with triangular white discal band, beginning at the apex in a fine point and terminating at the inner margin close to the anal angle with a breadth of 5 mm. Behind this a light brownish band with 5 small eye-spots, of which the 1st, 3rd and 4th are white and surrounded by brown and broad light ochre-yellow rings, the other 2 black, finely pupilled with white and margined with darker yellow. The basal area is finely striated with brown and bears 2 brown transverse lines. From Rio de Janeiro. Coll. HEWITSON in the Brit. Museum. Rare.

E. ordinata *spec. nov.* (47 a). Above olive-brown, at the distal margin somewhat darker with lighter *ordinata*. fringes. Beneath lighter brown. Forewing with indistinct line behind the middle, 2 brown lines before the margin and black-brown marginal line. Hindwing with broad white band, which runs from the middle of the inner margin across the discocellular to vein 6 near the apex and is not sharply defined on either side. Behind it is placed an orange-yellow band, which only extends from vein 1 b into cellule 4. On this are placed 3 small, round black spots, which are marked on their proximal side with a small, silvery crescent. A black dot is placed in cellule 4 at the end of the orange-yellow band. From Bolivia (coll. SEITZ). Similar to the preceding species, but easy to distinguish from it by the orange-yellow band, which is wanting in *pronophila*, as well as by the position of the white band, which in *pronophila* is placed more distally.

- ashna*. **E. ashna** Hew. (47 a). Above brown with small, obscure, darker spot at the anal angle. Beneath somewhat lighter. Forewing with 2 brown transverse lines and 3 marginal ones. Hindwing with a brown transverse line at the base, a straight white band from $\frac{3}{4}$ of the costal to $\frac{2}{3}$ of the inner margin and 3 black, white-pupilled eye-spots in cellules 2, 5 and 6, the first with double pupil and all margined with red-yellow. Between these eye-spots are placed in cellules 3 and 4 red-yellow rings with small, indistinct silvery centres.
- butleri*. The ♀ is marked like the ♂, but somewhat larger. From Colombia, Ecuador and Peru. — **butleri** Weym. (= *ashna* Btlr.) is a form of *ashna*, in which the ground-colour of the wings is above yellowish brown and beneath yellowish grey and the red-yellow rings in cellules 3 and 4 on the underside of the hindwing are as dark and enclose as large ocelli as those of the other cellules, forming a row of eye-spots of fairly uniform colouring. Ecuador. The name *butleri* Dist. is a synonym of *metaleuca* Bdv., hence *butleri* Weym.
- ambra*. can be retained for this *ashna* form. — **ambra** form. nov. (47 a) approaches *ashna* Hew. Hindwing somewhat more strongly dentate. Above brown with 3 darker marginal lines. Beneath somewhat lighter, especially in the marginal area and at the inner margin of the forewing. Hindwing with white band, almost as in *ashna*. The marginal area behind this band is almost entirely red-yellow, and separated from the band by a brown line. In it is placed in cellule 2 a round black spot with double pupil, another in cellule 5, but surrounded with red-yellow and brown ring and a similar but quite small eye-spot in cellule 6. At the distal margin in addition to the 3 parallel marginal lines a 4th brown submarginal line as distal boundary to the red-yellow marginal area. Between the two inner lines a row of whitish (♀) or light grey (♂) spots. Bolivia, Peru (Cuzco), 2—3000 m.

Liturata Group.

- liturata*. **E. liturata** Btlr. Above pale olive-brown, at the margin darker, fringes reddish grey. Beneath darker, covered with numerous short dark brown streaks, at the costa mixed with whitish. Forewing before the apex with a small black, white-pupilled eye-spot, ringed with ochre-yellow, and with 2 similar, extremely small ones below it. Hindwing on the somewhat lighter brown discal band with 5 equally small eye-spots, of which only the 2nd and 5th are somewhat more distinct. Marginal line black. Locality unknown. Coll. HEWITSON in the Brit. Museum.
- luttela*. **E. luttela** Weeks. Above bronze-brown, somewhat glossy, beneath the same colour, without gloss. Forewing between the dark brown marginal line and the distal margin at the apex dusted with yellow, an indistinct brown submarginal line, inner margin grey. On the hindwing the interspace between the 2 dark brown marginal lines is reddish-yellow. A small reddish yellow spot at the anal angle, containing a black central dot. 29 mm. Alezuni in Bolivia. Flies in August. Resembles *liturata* Btlr., but the eye-spot at the apex of the forewing is absent.
- vesper*. **E. vesper** Btlr. Allied to *liturata*. Above olive-brown. The eye-spots of the under surface are faintly visible above. Under surface copper-coloured, marbled with brown. Marginal line black. Forewing with dark brown discal and submarginal lines, below the apex a single black eye-spot with yellow ring and white pupil. Hindwing with 5 similar ocelli. The 2nd and 5th larger. A brown irregular discal line and the angled submarginal line unite before the inner angle. The club of the brown antenna is rust-coloured. Locality unknown. 35 mm. Coll. HEWITSON in the Brit. Museum.
- armilla*. **E. armilla** Btlr. (47 a). Above olive-brown, according to BUTLER with a very indistinct eye-spot on the hindwing at the anal angle, which is wanting in the example figured. Marginal line black. Under surface brown with dark brown discal, submarginal and double marginal lines on both wings. The ground-colour is somewhat lighter outside the submarginal line before the apex of the forewing and at the margin of the hindwing. A black, white-pupilled eye-spot with ochre-yellow ring before the apex of the forewing and 6 similar eye-spots on the hindwing, which vary but little in size. From the Brazilian provinces of Minas Geraes and Matto Grosso (Cuyaba). According to Herr BANG-HAAS *armilla* and the following *strigillata* are seasonal forms of one species. Further observations in respect to this are needed, however, as the forms are very different.
- strigillata*. — **strigillata** form. nov. (47 a). Above olive-brown, the central area of the forewing from the subcostal to the median covered with thicker, velvety, raised scales, hence standing out more darkly. Fringes grey. Under surface: forewing olive-brown, finely striated with brown all over, the apex brownish grey, also the distal margin, but more narrowly, likewise striated with brown. 2 marginal lines and a submarginal dark brown. Somewhat further back a 4th brown line, which does not reach the inner margin. Between the last-named lines 2 white dots and above them an ochre-yellow eye-spot with white pupil and brown ring. Hindwing grey, marbled with brown, basally darker, at the distal margin lighter with 5 small red-yellow eye-spots, which are white-pupilled and brown-margined. From Cuyaba in the province of Matto Grosso in Brazil.
- arius*. **E. arius** spec. nov. (47 a). Similar to *armilla*. Above brown with 2 darker marginal lines and a strongly dentate submarginal line on both wings. Hindwing with a small round black spot in a somewhat lighter ring at the anal angle. Under surface brown, on both wings dusted with grey at the distal margin. 2 almost straight transverse lines before and behind the middle on both wings, a dentate submarginal line and 2

marginal lines, straight on the forewing, undulate on the hindwing. On the hindwing 5 black ocelli with white pupils and ochre-yellow rings, the 2nd and 3rd ocelli smaller. Sometimes in addition a very small eye-spot in cellule 1b close to the inner margin between the median lines. From the Mapiri.

E. viridicans *spec. nov.* (47 b). Above olive-brown. Beneath much lighter in consequence of having *viridicans*. both wings dotted with greenish grey. The dark brown median lines, the dentate submarginal and the 2 marginal lines are as in the preceding species. On the forewing a small eye-spot in cellule 5, black with white pupil and yellow ring, an indistinct, still smaller ocellus in cellule 3. On the hindwing 5 distinct eye-spots, the 3rd and 4th small and brown, the others black with yellow rings and white pupils, the 3rd to 5th bi-pupilled, 37 mm. From Peru.

E. monahani *Weeks*. Above dark brown, margin somewhat lighter. Forewing beneath black-brown *monahani*. with grey marginal line, brown submarginal line and grey apex. Between the median veins (WEEKS says: above the lowest submedian nervule!) a black eye-spot with white pupil and light brown ring. Above it 2 small white dots and before the apex a small yellow spot. Hindwing proximally black-brown, distally light brown mixed with grey, the distal margin somewhat darker, marginal line grey, a marginal and a submarginal line brown. At the anal angle in cellule 1c a small yellow spot, in cellule 2 a yellow eye-spot with white pupil. From the inner margin a dark brown line runs to the cell. Sometimes the eye-spots are indistinct and the distal margin less grey. 35 mm. From Alezuni in Bolivia. August.

E. therkelsoni *Weeks*. Above dark brown, distally somewhat lighter. Beneath the same, forewing *therkelsoni*. with light brown marginal line, a dark brown, dentate marginal line and a 2nd similar transverse line behind the middle. These lines are indistinct on the forewing, on the hindwing they are repeated, but are more distinct, and join at the anal angle, and there is here an additional, indistinct line in the middle of the cell. Eye-spots and dots are not mentioned in the original description of this species. 38 mm. From the environs of Cochabamba in Bolivia. August.

Ocypete Group.

E. ocypete *F.* (47 b). Above brown with 2 somewhat darker median bands, a double marginal and a dentate submarginal line, in the anal angle of the hindwing a black eye-spot with double white pupil and yellow ring. The eye-spot is sometimes absent. Beneath light brownish grey with 3 broad brown stripes across both wings, to which is added on the hindwing a short 4th stripe at the base. On the distal stripe on the forewing 1 or 2, on the hindwing 5 eye-spots, black with yellow ring and glossy white double pupils, only the 2nd and 4th are brown. Surinam, Pará. — **helle** *Cr.* (47 b), a form of *ocypete*, has on the upper surface dark blue-grey ground-colour with bluish gloss, black veins and 3 black marginal lines, between which the ground-colour is somewhat lighter. The black eye-spot at the anal angle of the hindwing with fine white double pupil. The under surface is similar to that of *ocypete*. Ground-colour bluish white-grey with broad brown bands. On the forewing 3 ocelli, one distinct and 2 obscure, hindwing with 5 eye-spots, all with double silver pupils and yellow iris, the 2nd and 5th black, the others brown. Surinam, Amazons (Iquitos). — **lethra** *Möschl.*, likewise a form of *ocypete*, is above brown; on the underside of the hindwing the eye-spots in cellules 3 and 4 placed more proximally, so that the proximal margins of the entire row of eye-spots form a straight line. The eye-spot in cellule 6 is considerably larger. Further in *lethra* the two transverse stripes of the hindwing run straight into the inner margin, whilst in *ocypete* the outer of these stripes is curved basad at the inner margin, the inner somewhat distad. From the interior of Surinam.

E. myncea *Cr.* Above with a small eye-spot before the apex of the forewing and a similar one at the anal angle of the hindwing. Beneath brownish grey, in the basal area of both wings 2 straight brown stripes, which are both bent basad at the inner margin of the hindwing. On the dark brown discal band, which is 3—4 mm in breadth, are placed on the forewing 3, on the hindwing 5 ocelli, all of nearly equal size, measuring 2—2½ mm in diameter and standing in a straight row, all black with red-yellow ring and silvery blue double pupil. At the margin a brown submarginal stripe and 2 fine marginal lines. 43 mm. From Surinam.

E. thobici *Capr.* is placed by its author as a separate species near to *myncea* and the following differences are given. The two brown transverse stripes in the basal half of the *under surface* are curved and enclose a band, which is somewhat darker than the rest of the ground-colour. Of the three large eye-spots on the forewing of *myncea* the first is scarcely perceptible and the other 2 are almost entirely obsolete. Of the 5 eye-spots of the hindwing the first, second and fifth are very distinct, the last-named somewhat larger, the other two indistinct. All else as in *myncea*. 38 mm. From the province of Rio de Janeiro.

E. nerita *Capr.* Likewise placed by its author in the *myncea* group, which species the wings resemble *nerita*. above except that the brown is darker. In the median area the transverse lines of the under surface show through and on the hindwing the ocellus at the anal angle is present. The under surface is much lighter, the two transverse lines terminate suddenly at the inner margin and are yellow-brown bordered with dark brown. The submarginal line is lunulate and is likewise yellow-brown bordered with dark brown. 3 almost invisible eye-spots on the forewing before the apex, on the other hand on the hindwing 6 distinct ones, the first two

and the fifth large, the others small, the sixth without pupil. 37 mm. Province of Rio de Janeiro. This species appears to belong to quite another group.

labe.

E. labe *Btlr.* Above brown, the forewing with round black spot before the apex, hindwing with black, red-yellow-ringed eye-spot with double silvery pupil, two brown marginal lines and a somewhat widened, undulate submarginal line. Beneath brownish white, 2 straight red-brown stripes across both wings, in the disc of the forewing a large reddish yellow spot, before the apex a black ocellus with red-yellow border and double silvery pupil, on the hindwing 5 eye-spots, of which 2 are larger and like the one on the forewing, the others smaller and brown instead of black. The submarginal line is double and close to the anal angle of the hindwing runs out into a quadrate light rust-red spot. *labe* is distinguished by this spot from the following form. 43 mm. Flies in low-lying districts of Mexico, Guatemala, Honduras, Nicaragua, Costa Rica, Panama and Colombia. — **confusa** *Stgr.* (47 b) is a form of *labe* which varies very much in size (34—46 mm.), but only differs in that the light rust-red spot at the anal angle on the underside of the hindwing is not present and on the upperside of the same wing there are indistinct, obscure dark brown spots in cellules 3 to 5. Its area of distribution is about the same as in *labe*, but in South America *confusa* extends as far south as Ecuador. It is also commoner than *labe*.

palladia.

E. palladia *Btlr.* (47 b). Above brown, 2 dark brown stripes in the basal half, 2 marginal and an undulate submarginal line, an eye-spot at the apex of the forewing and one at the anal angle of the hindwing with double pupil. Beneath white, 2 median bands, 2 marginal and an undulate submarginal line brown, the proximal lines at the anal angle of the hindwing broader and yellow. Forewing with 3 eye-spots ringed with yellow and brown before the apex, some silver dots and below them a rather large red-yellow spot. Hindwing with 5 eye-spots, the first small and black, the second and fifth large and black, the others brown, all with silver double pupils; in addition a small indistinct ocellus close to the inner angle. From Tapajos, Amazons, Anariver.

terrestris.

E. terrestris *Btlr.* (47 b). Above brown with 2 dark brown median bands, a submarginal and 2 marginal lines, at the anal angle of the hindwing an eye-spot with white pupil and yellow-brown ring. Beneath brownish grey with 2 red-brown median bands. Forewing with the usual apical eye-spot and 2 silvery spots below it. Hindwing with 5 eye-shaped spots, the first, second and fifth black with yellow ring and double silvery pupil, the silver dot of the others is elongated and bordered with orange-yellow. Surinam, Amazons, Matto Grosso (Cuyaba).

moneta.

E. moneta *spec. nov.* (47 b). Above olive-brown, with 3 parallel marginal lines on both wings. A small black eye-spot with white pupil and red-yellow ring before the apex of the forewing, a somewhat larger one with silvery double pupil at the anal angle of the hindwing and an indistinct one without pupil and with a brown ring in cellule 5 of this wing. A slight indication of a dark band traverses both wings. Beneath white-grey, with 2 straight parallel brown bands through the middle, the proximal narrower, the distal broader, the latter somewhat washed-out at the proximal side. Before the apex of the forewing a black eye-spot with 2 distally placed silvery pupils just above it and thick silver spots one above the other, just below it 4 similar silver spots in a straight row. Then follows a large reddish-yellow spot. On the hindwing there are two large black ocelli with double silvery pupils (oblique in the anterior ocellus) and red-yellow and dark brown rings. Between these eye-spots 2 large heart-shaped silver spots and close to the costal margin 2 further silver spots, which are similar to those on the forewing. The submarginal line of this species has one peculiarity which does not occur in any of the preceding. It consists of small arcs, 2 placed in each cellule, the convexity distally directed and the points proximally. In this the species resembles the following *penelope*. From Cayenne.

penelope.

E. penelope *F.* (= *clarissa* *Cr.*) (47 b). Above yellow-brown with 2 dark brown median bands, 2 marginal lines, finely dentate submarginal line, an eye-spot on the forewing before the apex, in the ♂ without, in the ♀ with silvery pupil. Hindwing in ♂ and ♀ with a similar eye-spot with double silvery pupil at the anal angle and an obscure eye-spot at the apex. On the brownish grey under surface the species is distinguished by having the submarginal line as finely dentate as in the preceding species (*moneta*) and at the proximal side of this line a stripe 2—3 mm. in breadth, sprinkled over with a number of scattered dark brown scales. On the forewing 1 eye-spot, on the hindwing 2 with double silvery pupils and several silvery spots. Brazil, Amazons, Surinam. — **pytheus** *Möschl.* is a form similar to *penelope* with only one light-yellow-bordered eye-spot at the anal angle of the hindwing, the brown discal band on the underside of the forewing extending nearly to the inner margin, the submarginal line with shallower arcs and the brown dots wanting. From Paramaribo (Surinam).

similis.

E. similis *Btlr.* The form of this species figured by GODMAN and SALVIN in the Brit. Centr. Am. is regarded as the type, BUTLER having mixed 2 forms in his original description. 40 mm. On the under surface the ground-colour is light brown as far as the second transverse line behind the middle, marginal area whitish grey traversed by a light brown discal band, on which in cellule 2 of the hindwing are placed a black eye-spot

with a yellow ring and a black spot above it. There are no other ocelli. Two fine brown marginal and an undulate submarginal line. From Mexico and Guatemala (! Nicaragua). — *themis* Btlr. is a very similar form, in which the discal band on the underside of the hindwing is quite faint, so that the eye-spots, of which there are 4 on the forewing and 5 on the hindwing, stand out distinctly. They have all yellow iris and double blue pupils, the second and fifth on the hindwing are black and larger than the others, in addition there is a very small sixth eye-spot close to the inner margin of the hindwing beside the first median band. Of the three approximated marginal lines the middle one is somewhat thickened near the inner margin. Mexico, Guatemala, Honduras, Nicaragua, Panama, Colombia, Venezuela, Trinidad. — *undina* Btlr. (47 b) is a form of *similis* in which the inner of the two marginal lines on the upperside of the hindwing is twice as broad as the outer. Between the two is placed a lighter line. The submarginal line is somewhat separated. A black eye-spot with white double pupil and yellow ring in cellule 2. On the under surface of the hindwing the dark dusting on the inner submarginal line is strongly expressed, especially near the inner angle. The brown discal band is distinct and shows on the forewing 1, on the hindwing 5 ocelli. 40—42 mm. From Mexico.

E. cleophes Godm. & Salv. Above grey-brown with 2 broad, brown median bands, an undulate submarginal and 2 marginal lines, a black eye-spot with yellow ring and white double pupil before the apex of the forewing, a similar one at the anal angle of the hindwing and a round red-yellow spot between medians 1 and 2 in the disc of the forewing. Beneath the basal area is light grey with 2 reddish grey transverse lines; marginal area almost white with the same eye-spots and red-yellow spot as above, but with a similar eye-spot also in cellule 5 on the hindwing. Between and beside the eye-spots silver dots. 38 mm. Mexico (Acaguizotla, Tierra Colorada and Dos Caminos in Guerrero).

E. castrensis Schaus (47 c). Approaches *undina*. ♀ above brown with 2 marginal lines, a submarginal and 2 median lines, of which the proximal one may also be absent. Hindwing with a black dot at the apex, 2 ocelli at the anal angle, black with white pupil and yellow ring, the larger before vein 2, the smaller behind it. Beneath brownish fawn-coloured, the lines darker than above, forewing with an eye-spot and several brown rings which contain scattered yellow scales. Hindwing in the disc whitish with two larger ocelli in cellules 2 and 5, three smaller ones in cellules 1 c, 3 and 6, and also two placed obliquely and close together in cellule 4. The ♂ is darker, the black dot at the costal margin of the hindwing above is absent. On the under surface the forewing has only a black dot in cellule 5 and on the hindwing instead of the eye-spots in cellules 3 and 4 there are lilac spots with brown bordering. From Brazil: St. Leopoldina and Castro (Parana).

E. usitata Btlr. (47 A). Above brown with a dark, straight line behind the middle and 3 marginal lines. Forewing in the ♂ without, in the ♀ with a small eye-spot before the apex, hindwing with 2 eye-spots, black with yellow ring and double white pupil, the larger in cellule 2, the smaller in cellule 3. Under surface lighter than above, with 2 transverse lines through the middle, the forewing with silvery dots below the eye-spot, hindwing with 5 ocelli, the first 2 and the last black with double white pupil (only that of the second is single), the others brownish grey with silvery pupil, but all placed in ochre-yellow rings, surrounded with brown. Venezuela. — *pietria* Btlr. is a form of *usitata*, which on the upper surface has only one eye-spot at the anal angle of the hindwing and in which the median lines on both surfaces are strongly curved basad before the inner margin of the hindwing. From Mexico, Guatemala, Honduras, Nicaragua, Costa Rica, Panama. — *pompilia* Fldr. (47 c), a further form of *usitata*, which GODMAN and SALVIN in the Biol. Centr. Amer. state is synonymous with *pietria*, differs according to our figure drawn from the type in ROTHSCHILD's collection in that the median line of the hindwing on both surfaces runs straight to the inner margin; moreover this figure shows at the costal margin of the hindwing above 2 eye-spots, which BUTLER does not mention in his description of *pietria*. From Colombia and Mexico. — *thelete* Snell. is likewise a form of *usitata*, on the under surface quite similar to the type-form, except that the silver dots below the eye-spot on the forewing are absent. Above *thelete* is confusingly like our figure of *pompilia* Fldr., as in addition to the anal ocellus it possesses the same 2 eye-spots at the apex of the hindwing, only somewhat larger. From the island of Curaçao.

E. austera Btlr. Forewing above olive-brown, with a black eye-spot with silvery double pupil and yellow ring before the apex. Hindwing with 2 similar ocelli at the anal angle, the outer one larger; in the middle a brown curved band, on the margin a brownish yellow terminal line. Beneath grey, before the middle a narrow, behind the middle a broad yellow-brown band across both wings. Then follows in the disc an ochre-yellow band, in which is placed on the forewing one eye-spot as above, on the hindwing 5, the second and fifth black with white pupils and yellow and outer dark brown ring, the others composed of silvery spots margined with ochre-yellow. The margin brown with an ochre-yellow marginal line. 42 mm. From Bogotá.

E. divergens Btlr. (47 c). Above olive-brown with three dark marginal lines. The other bands and the eye-spots of the under surface show through faintly above. Under surface lighter with 2 rust-coloured, brown-edged median bands, of which the outer one on the forewing is curved strongly distad at the inner margin. On the forewing 1, on the hindwing 5 ocelli, some of which are black with silvery double pupil and some silvery

with brown bordering, but all are surrounded by ochre-yellow rings. In the ♀ there is further a small eye-spot in cellule 2 of the forewing. From Surinam and the Rio Negro (Amazons).

eurytus.

E. eurytus *F.* (= *eurytris F.*, *eurythris Godt.*, *cymela Cr.*) (47 c). This species is rather common in North America and is easy to recognize by the 2 eye-spots which are placed on the upperside of both wings, of which only the anterior one on the hindwing is less developed in the ♂♂, and may also be absent. In the ♀ there is sometimes on the hindwing a 3rd smaller ocellus between median and submedian. On the light grey under surface are placed on the forewing 2, on the hindwing 4 eye-spots with double silvery pupils and between them further silver dots. — The egg is higher in proportion to its breadth than that of *E. cornelius*, to which it is otherwise fairly similar. The full-grown larva, according to BOISDUVAL and LECANTE, is green with 5 white longitudinal stripes (1 dorsal stripe and 2 at each side); according to HOLLAND it is in its earlier stages yellow-brown with a lighter silky stripe and brown spiracles. It lives on grasses. The pupa is light brown with 2 rows of dark dorsal dots, a white line at each side and white bordering to the wing-cases. It is suspended from grass-stems. The butterfly is distributed in North America from Canada through the United States to Nebraska, Kansas and Texas.

periphas.

E. periphas *Godt.* (47 c). Distinguished from *eurytus* by having only one eye-spot on the upperside of both wings and the underside of the forewing, on the forewing before the apex, on the hindwing before the anal angle. But examples also occur in which on the hindwing above a 2nd very small eye-spot is present at the anal angle. Beneath there are 3 ocelli on the hindwing and between them some fine silvery dots. The pupils of all the eye-spots are much smaller than in *eurytus*. From Brazil and Uruguay.

ocelloides.

E. ocelloides *Schaus* (47 c). Similar to the preceding species, but considerably smaller. Wings more rounded and above lighter. Ground-colour brownish grey, hence the deep black eye-spots stand out more distinctly. Above with one ocellus on the forewing before the apex and one on the hindwing before the anal angle, sometimes two in the ♀. On the under surface the species is at once distinguishable from *periphas* by the course of the brown transverse line behind the middle of both wings. Whilst in *periphas* this line is fairly straight and runs parallel with the distal margin, in *ocelloides* it is curved several times and on the forewing runs obliquely to the inner angle. Ypisanga, São Paulo, Castro in Parana (Brazil).

biocellata.

E. biocellata *Godm.* (47 d). Above brown with black, white-pupilled double ocellus in red-yellow ring, the hindwing without eye-spots. Beneath the forewing somewhat lighter, the eye-spot as above, but surrounded further by 2 brown lines, of which the outer one extends in a large curve nearly to the anal angle. The distal half of the hindwing is white-grey and traversed by a darker band, which is intersected with white on the veins. From Bolivia (Tanampaya) at about 2000 m.

rubricata.

E. rubricata *Edw.* Above brown, forewing with a large rust-red spot between the median veins and a black eye-spot with red-yellow ring and white pupil before the apex, hindwing with a similar eye-spot at the anal angle. Both wings with 3 dark brown marginal lines. On the under surface the forewing is grey-brown and the basal area bright rust-red, ocelli and marginal lines as above, a red stripe running from the costa to the inner margin, two silvery blue double pupils placed below the eye-spot. Hindwing with a brown stripe, proximally margined with light grey, which runs from the costa to the inner margin, and a row of 5 eye-spots before the margin, the first large, the others indistinct, but indicated by silver spots. 35 mm. From Texas, Mexico (North Sonora), Guatemala.

pellonia.

E. pellonia *Godm.* Similar to *rubricata*. Above brown, forewing in the middle reddish, before the apex a black ocellus with white pupil, red-yellow ring and outer dark brown bordering, at the edge of this a further white dot. In addition a light brownish crescent basally to the ocellus and beside it a dark brown dentate transverse line, which runs obliquely distad to the inner angle and is continued also in a large curve across the entire hindwing. A dentate submarginal and 2 continuous marginal lines on both wings. Beneath as above, but the brown oblique line and the crescent on the forewing are absent, on the other hand on the hindwing a third dentate transverse line is present in the basal area. In this species there are no eye-spots on the hindwing either above or beneath. 42 mm. From Mexico (Milpas and Ciudad in Durango; Bolaños in Jalisco, Chapala).

lethe.

E. lethe *Btlr.* Above dark brown with two marginal lines, hindwing with undulate discal line and a black anal eye-spot. Beneath much lighter, with 2 dark median lines, the proximal angled, the distal undulate; marginal lines as above. Forewing with 2 ocelli in cellules 2 and 5, which are black with white pupils and yellow rings. Hindwing with 2 similar eye-spots in the same cellules and also 2 smaller ones close to the anal angle, in addition with 2 brown eye-shaped dots between the ocelli. 36 mm. From Venezuela.

argante.

E. argante *Cr.* (= *argulus Godt.*). Above brown with 3 dark brown parallel marginal lines and a white line between the two distal dark lines. Under surface lighter, the white line with a silvery gloss, the other marginal lines as above, in addition 2 brown lines through the middle of both wings, on the hindwing almost straight, on the forewing diverging anteriorly. On the forewing 4 eye-spots in a straight row, on the hindwing 5 in an angular row, some of them bi-pupilled. 40 mm. From Surinam.

E. maepius *Godt.* (47 d). Above brown with 2 marginal lines and a dentate submarginal at some distance from them. On the hindwing with a whitish line between the marginal lines. Forewing with 2 dark brown dots in cellules 2 and 5, hindwing with 3 ocelli, a large one in cellule 2 and two small in cellules 3 and 4. All black with yellow ring, the posterior 2 with white pupils. Under surface lighter with 2 darker lines through the middle. Forewing with 4 small eye-spots, hindwing with 5 ocelli, of which the posterior 4 are larger, some black and some brown, all with double silvery pupils and yellow rings. From Guiana and Brazil. *maepius.*

E. erigone *Btlr.* (47 d). Above olive-brown with dark line behind the middle and 3 marginal lines. Forewing without eye-spots, hindwing with 5 black, yellow-ringed ocelli, of which the 4th is large and blue-pupilled, the 5th small with silvery pupil, the 2nd indistinct. Under surface lighter with 2 brown median lines, angled at the inner margin of the hindwing, and 3 marginal lines (the proximal one undulate), apex of the forewing brownish yellow with a brown band and 3 eye-spots in yellow rings (the lowest larger and with 2 blue pupils). From São Paulo in Brazil, Peru. — **probata** *form. nov.* (47 d). Similar to *erigone*, but above with only a black dot at the anal angle of the hindwing in place of the ocelli. The under surface agrees entirely with *erigone*. From the Mapiri. — **proba** *form. nov.* (47 d). Likewise similar to *erigone*. On the upper surface there is only one black eye-spot, with red-yellow ring and double silvery white pupil, placed at the anal angle of the hindwing. On the under surface the forewing has only one eye-spot and instead of the 2 lower ocelli of *erigone* there are 3 small silver dots. The silvery pupils in the eye-spots in cellules 3 and 4 on the hindwing are prolonged into silvery streaks. The distal of the two dark brown median stripes is somewhat broader than in *erigone*. Peru. *erigone.* *probata.* *proba.*

E. argyropsila *Btlr.* Above brown with 3 marginal lines, of which the proximal is undulate. Forewing with small black dot at the inner angle, hindwing with 3 black ocelli in ochre-yellow rings, the middle one large and with violet pupil. Beneath yellowish brown with 2 darker median lines, of which the distal forms a tooth in the middle of the hindwing, with 3 marginal lines. Forewing with 4, hindwing with 5 yellow-ringed eye-spots, some black with silvery double pupils, the others brown with violet single pupils. 38 mm. From Ega (Amazons). — **nausiaca** *Möschl.* Similar to *argyropsila*, but the forewing above with 2, the hindwing with 5—6 eye-spots, all ringed with red-yellow, but mostly blind, only those in cellules 2 and 3 having silvery pupils. Beneath like *argyropsila* in the number of the ocelli, but both the median bands are basally curved before the inner margin of the hindwing, and the tooth of the distal median line in the middle of the hindwing is wanting. From Paramaribo and the interior of Surinam. *argyropsila.* *nausiaca.*

E. crantor *F.* is a doubtful species for America. According to FABRICIUS the upper surface is brown, the forewing without spots, hindwing with a black eye-spot with double pupil. Beneath lighter, with darker bands, forewing with 2 eye-spots, hindwing with 5, of which the 1st and 4th are black with double pupil, the 3rd and 5th blind. FABRICIUS gives the size as the same as that of the Indian *Mycalesis mineus* *L.*, which measures 44—46 mm. As locality he mentions India. DONOVAN in his *Insects of India* figures under the name *crantor* a species which agrees with that of FABRICIUS in the number of eye-spots, but not in the number of pupils. GODART copies FABRICIUS' description and adds: „From Brazil.“ WESTWOOD in *Genera Diurnal Lepid.* gives as locality Brazil, Pernambuco and Honduras and mentions that the species is in the British Museum, which according to BUTLER (*Proc. Zool. Soc.* 1866, p. 467) is not correct. GODMAN and SALVIN, however, regarded the Honduras examples referred to by WESTWOOD as belonging to *E. labe* *Btlr.* The figure in DONOVAN is similar in the scheme of markings to the following *ocnus*, but the ground-colour of the underside is more rust-red in *crantor*. *crantor.*

E. ocnus *Btlr.* (47 d). Above brown with 3 dark marginal lines, of which on the forewing only the middle one, on the hindwing all three are undulate. At the anal angle of the hindwing a black patch bordered with red-yellow. Beneath lighter, somewhat inclined to violet, with 2 reddish brown median bands, of which the proximal is directed distad at the costa of the forewing, 3 undulate marginal lines; forewing with 1 to 3 small eye-spots before the apex on a brown band, hindwing with 5 eye-spots, the 2nd and 5th large with silvery double pupils, the first the same, but small, the others red-yellow marked with thick silver spots, all margined with brown. From Tapajos (Amazons). — **opima** *form. nov.* (47 d) is a form of *ocnus* which differs on the underside of the hindwing in the 3rd and 4th eye-spots having a brown dot in the middle instead of the silver spots and on the upperside in the dark patch not being bordered with red-yellow. From Jurua. — **pallema** *Schaus* is a further form of *ocnus*, the upper surface altogether without eye-spots or dark patches, but beneath quite similar to the type-form. From Peru. *ocnus.* *opima.* *pallema.*

E. eriphule *Btlr.* Above brown with 3 dark brown undulate lines at the margin and an indistinct dot at the anal angle of the hindwing. Beneath lighter with a thin brown line before the middle, a broader one beyond the middle, the latter broadly bordered distally with light violet and angled at the inner margin of the hindwing; 3 black marginal lines. Forewing without eye-spots, hindwing with 5, ringed with red-yellow, the first 2 and the last black with silvery pupils, the others with thick, oval, silvery dots. 37 mm. From Pernambuco (Brazil). *eriphule.*

E. electra *Btlr.* Dark brown with 3 black marginal lines and a black anal eye-spot with brown ring and blue pupil. Beneath somewhat lighter with the same marginal lines. Forewing with an oblique transverse *electra.*

line behind the middle and without eye-spots, hindwing with 2 median lines and 5 yellow-ringed ocelli, the first 2 and the last black, the others brown, the first 2 with single, the last 3 with double lustrous blue pupils. The ♀ has beneath before the apex of the forewing a yellow dot and below it one larger and 2 smaller, obscure eye-spots. 42 mm. Bahia.

variabilis. **E. variabilis** Btlr. Above olive-brown with lighter fringes, 2 dark marginal lines and an undulate submarginal line at some distance from them. Forewing with a faint band behind the middle. Hindwing with 2 black, brown-bordered eye-spots before the anal angle, the upper and larger has 2, the lower only one pupil. On the lighter under surface the forewing towards the apex is sprinkled with brown, with 2 widely separated median lines. The 3 marginal lines as above, without ocelli. Hindwing somewhat inclining to violet, at the base sprinkled with brown, with 2 median lines, the distal one forming an angle in the middle and with 6 ochre-yellow-ringed eye-spots, of which the 3rd is indistinct, the rest some black, some brown and for the most part with double pupils. Aberrations occur with smaller eye-spots. 45 mm. From Brazil (Pernambuco, Rio de Janeiro).

urbana. **E. urbana** Btlr. (47 e). Above olive-brown, an undulate submarginal and 2 marginal lines darker, between the latter at the anal angle of the hindwing a brick-coloured line, beside it 2 oval black eye-spots, the distal one in cellule 2 twice as large as the proximal, both with brick-coloured rings and silvery pupils. The under surface is sprinkled with dark brown, the 2 rust-coloured median lines diverge towards the costa of the forewing, but run parallel on the hindwing, the proximal forms a short angle on the forewing, the distal on the hindwing. Forewing with one or 2 blind eye-spots, hindwing with 6 eye-spots, of which the 2nd and the last 2 are darker and larger than the rest, but all have silvery pupils. From Colombia and Paraguay.

affinis. **E. affinis** Btlr. Above pale brown with 3 dark marginal lines, between which on the hindwing is placed an ochre-yellow line. A black, blue-pupilled and yellow-ringed ocellus at the anal angle of the hindwing. Under surface ochreous with 2 brown median lines, the proximal straight, the distal on the forewing curved distad at the costal margin, but on the hindwing uniting at the inner margin with the partly angled, partly undulate submarginal line. In the marginal area a brown band, on which in the forewing are placed 3, in the hindwing 5 ocelli, the first on the forewing, the 1st, 2nd and 5th on the hindwing black, the others brown, but all with double silvery pupils and ochre-yellow rings. 42 mm. From Rio de Janeiro, Pernambuco.

vestigiata. **E. vestigiata** Btlr. Above olive-brown, 2 median and 3 marginal lines dark brown, 2 very small ocelli with silvery pupils at the anal angle of the hindwing. Beneath much lighter, sprinkled with a number of brown atoms, 2 narrow, yellow, fairly straight median stripes bordered with black at both sides, which only form an angle at the inner margin of the hindwing. The strongly dentate submarginal line is similarly coloured on the hindwing, black on the forewing. Forewing with 3 eye-spots, the first, with yellow ring and silver pupil, before the apex, the others indistinct. Hindwing with 6 eye-spots, the 2nd and 5th black with double silvery pupils, the two middle ones brown and dusted with silver scales, the two outer only small, but all ringed with yellow and brown. 40 mm. From Minas Geraes.

ochracea. **E. ochracea** Btlr. (47 e). Above unicolorous olive-brown, distal margin somewhat darker. Beneath yellowish brown, finely dusted with brown, with 2 straight brown median lines, diverging anteriorly, a broad, light ochre-yellow band and a washed-out brownish one. On the latter are placed on the forewing 2, on the hindwing 6 small black eye-shaped spots in somewhat lighter rings, the 2nd and 5th finely pupilled with white. From Ypisanga (Brazil), coll. LÜDERWALD.

Renata Group.

renata. **E. renata** Cr. Above brown with a small eye-shaped spot at the hinder angle of the forewing in cellule 2. Beneath likewise brown, finely striated all over with dark brown, with 2 straight dark brown median lines, an undulate submarginal and 2 straight marginal lines, a small eye-spot before the apex of the forewing and 4 eye-spots on the hindwing, 2 at the apex in cellules 5 and 6 and 2 at the inner angle in cellules 1 b and 2. The eye-spot in cellule 2 measures $3\frac{1}{2}$ mm., that in cellule 5 $2\frac{1}{2}$ mm. in diameter, the others are smaller, all are black, with white pupils (the one in cellule 5 bi-pupilled) and bright, broad red-yellow rings. From Surinam. This species appears to have been hitherto misidentified, for the figures of *renata* in the Biol. Centr. Amer. and in STAUDINGER Exot. Tagf. do not agree with CRAMER's figure and text. In these figures the eye-spot on the upper surface of the forewing is wanting, of which CRAMER mentions the position very exactly in his description, and the under surface is much lighter, with the ocelli much smaller, than in CRAMER and ringed with pale yellow. I retain for this form, which must be separated from *renata*, the name **disaffecta** Btlr. (47 d). It has no eye-spot on the upperside of the forewing, but on the hindwing a distinct one with red-yellow ring and white pupil. The under surface is much lighter than the upper, especially in the marginal area. The ocelli are much smaller and ringed with pale yellow, and vary in number from 3 to 6. The first and the two middle ones are often very indistinct or entirely absent. Guatemala, Nicaragua, Costa Rica, Panama, Colombia, Venezuela, *remissa*. Amazons. — **remissa** form. nov. (47 e) is a form of the preceding, in which the eye-spot on the upper surface

at the anal angle of the hindwing has a double white pupil. On the under surface the two somewhat broader median stripes diverge towards the costal angle of the forewing, on the hindwing they run parallel, but bend round proximad at the inner margin, forming 2 teeth. Forewing with an apical ocellus, black with red-yellow ring and white pupil. Hindwing with 6 eye-spots, the first 2 and the last 2 like the one on the forewing except that the first is brown instead of black, the 2 middle ones yellowish brown. From Chiriquí. — *peloria* Fldr. *peloria*. (47 e) is a further form of *renata*, in which the first transverse stripe on the forewing is strongly curved on the under surface and the other is proximally shaded with yellowish brown. According to FELDER's description the hindwing has beneath 6 eye-spots, of which the first and the two middle ones are very indistinct. Our figure is from one of FELDER's types and shows only 3 eye-spots. Venezuela.

E. mythra Stgr. *i. l.* (47 e). Above olive-brown with 2 brown marginal lines, and at some distance from them an undulate submarginal, between the former on the hindwing a whitish line and at the anal angle a small black ocellus with white pupil and red-yellow ring. Beneath brownish grey, finely irrorated with brown and with 2 straight parallel median lines and in the lighter marginal area a brown band, on which on the forewing are placed 3 rather obscure eye-spots, on the hindwing 5 small ones. The first 2 and the last on the hindwing are black, the others brown, all with double dull white pupils and surrounded by ochre-yellow and outer brown rings. Bolivia.

E. abretia Capr. (46 f). Above light olive-brown. The straight light band on the under surface shows through somewhat above, and the 3 marginal lines are also visible. Beneath there is a brown, angled line before the middle, and in the marginal area of the hindwing a row of 6 fine black dots, the first with an extremely fine white pupil. Brazil (Valença, Petropolis). Flies in September.

E. angularis Btlr. (47 e). Differs somewhat in the shape of the wings. The apex of the forewing is obtuse. The hindwing is angled at the submedian and at medians 1 and 2, the inner margin somewhat excised. Above olive-brown, marginal lines and anal spot very indistinct. Under surface yellowish grey, finely irrorated with dark brown, with 2 straight reddish brown median lines, a strongly dentate submarginal line and 2 marginal lines on both wings. Forewing with 5 scarcely visible, white, brown-bordered dots (sometimes in yellow rings). On the hindwing 6 small eye-shaped spots or dots, of which the 1st, 3rd and 4th are scarcely visible, the others distinctly black with yellow rings, the 5th somewhat larger and bi-pupilled. Minas Geraes (BUTLER), Estação Raiz da Serra (Estado São Paulo); December (LÜDERWALD).

E. punctata spec. nov. (47 e). In the shape of the wings quite similar to the preceding species, but the under surface is quite differently marked. Above olive-brown, forewing without marginal lines, only the fringes somewhat lighter. Hindwing with 2 marginal lines, the distal indistinct, the proximal darker and distinct, with an obscure submarginal line composed of large lunules. Under surface yellowish grey, with slight darker irroration. A fine, brown dentate line runs through the cell of both wings with single darker dots on the veins, in the distal half of the wings 2 broad light parallel stripes, the proximal yellowish, the distal whitish yellow. Proximally to the first stripe there is a row of fine black dots on the veins, connected by proximally directed brown lunules. A similar row of dots is placed outside the distal stripe, on which are placed the distally directed lunules of the submarginal line. These lunules likewise bear black dots in the middle of the cell. Two further rows of dots (the 4th and 5th) are placed on the almost straight marginal lines, which are only undulate in the posterior part of the hindwing. There is also a single black dot with white pupil in cellule 2 between the 2 lighter stripes. From Minas Geraes (Brazil), coll. WEYMER.

E. straminea Btlr. Forewing somewhat longer, the apex consequently more pointed than in the allied species. The distal margin of the hindwing forms an obtuse angle on vein 3. Above olive-brown, in certain lights copper-coloured, with 2 brown marginal lines, an undulate submarginal line and an indistinct anal ocellus. Beneath ochre-coloured, finely dusted with brown, in the disc pale rose-red, 2 widely separated brown median lines, the distal one proximally margined with yellowish brown, marginal lines as above, between them a yellow line. In the disc a brown band, on which are placed on the forewing 1, on the hindwing 4 eye-spots (2 at the apex and 2 at the hinder angle), all with yellow ring and glossy white pupil, sometimes double. 50 mm. From Minas Geraes (Brazil).

E. celmis Godt. (47 f). Above brown with 2 dark brown lines and a distal black line at the margin, between which the ground-colour is somewhat lighter, with a small yellow-ringed eye-spot at the anal angle, in the ♂ without, in the ♀ with pupil. Beneath brownish grey, finely irrorated with brown, with 2 angled darker lines through the middle and the 3 marginal lines as above, 1 ocellus on the forewing and 5 or 6 on the hindwing, all small, the 2nd and 3rd on the hindwing mostly indistinct, the others black with yellow ring and fine white, mostly double pupils. From Brazil, Argentina, Paraguay. Common. The species varies as regards the number of the ocelli and their distinctness, also the size ranges from 34—44 mm. — *melchiades* Btlr. is a form of *celmis* in which on the hindwing above 2 eye-spots are present at the anal angle, of which the first is 3 times as large as the last. On the under surface there are 5 small ocelli on the forewing, the 2nd somewhat larger,

and 6 on the hindwing, the 2nd and 5th being the largest and the 3rd consisting of 2 eye-spots obliquely adjoining one another. From Cordoba. — **bonariensis** *Burm.* (47 f) is a further form of *celmis*, which on the upper surface has neither eye-spots nor dots and beneath only brown rings instead of the eye-spots. From Buenos Aires.

grimon. **E. grimon** *Godt.* (47 f). Above olive-brown with undulate submarginal and 2 dark brown marginal lines, between the latter on the hindwing a whitish grey line. Beneath light brownish grey, finely dotted with brown, with 2 dentate darker lines through the middle and the 3 marginal lines as above. Forewing with 3 eye-spots, only the first distinct, the others obscure. Hindwing with 5 eye-spots, the first 2 and the last black with double white pupil, the others composed only of brown rings with ochre-yellow pupils. From Brazil.

phronius. **E. phronius** *Godt.* (47 f). Above grey-brown, with indistinct darker marginal lines and similar submarginal line, also an indistinct dark dot at the anal angle of the hindwing. Beneath yellowish grey, finely dotted with brown all over, with 2 dentate darker transverse lines through the middle, on which at each vein is placed a dark brown dot. Marginal area somewhat lighter, containing 1—4 white dots on the forewing, 4—5 on the hindwing. Sometimes some of these dots are double or present incompletely formed dark rings. St. Catharina (Brazil).

acmenis. **E. acmenis** *Hbn.* (51 b). Above black-grey. Beneath more brownish grey, sprinkled with dark brown dots. The dark brown median lines are fairly straight on the forewing, on the hindwing strongly undulate and running parallel with the distal margin. The median area enclosed by them is dark brown on the hindwing. The marginal area becomes gradually darker towards the distal margin, but shows no eye-spots or dots. The fringes light brownish. The locality of this species is unknown, for that given by HÜBNER (Baltimore) is incorrect. It resembles the preceding species, but the median band is much more strongly curved in *acmenis* and the white dots in the marginal area, as well as the dark brown dots on the median lines, are absent.

Paeon Group.

paeon. **E. paeon** *Godt.* (51 b). Margin of the hindwing obtusely dentate, in the ♂ more strongly, in the ♀ more weakly. Above grey-brown, with an undulate submarginal and 2 marginal lines dark brown. Of the latter the inner is proximally widened and on the hindwing forms crescentic spots between the veins. An undulate whitish line between these marginal lines. At the anal angle of the hindwing a small, round, dark brown spot, which in the ♀ is larger, in the ♂ smaller or absent. Beneath there are on the forewing in addition to the lines of the upper surface 2 straight median lines and a small eye-spot before the apex. The hindwing is brownish grey or brownish yellow in the basal half and at the costal margin, becoming gradually darker posteriorly, marbled all over with dark brown. Two dark brown, strongly dentate transverse stripes run from the costal to the inner margin. In the marginal area 4 small black eye-spots with double white pupils, 2 at the apex and 2 at the inner angle. Rio de Janeiro and St. Catharina. — **marmorata** *Btlr.* (47 f) is a form of *paeon* in which the under surface is much lighter and the dark brown posterior half of the hindwing in the type-form is restricted to a dark spot at the distal margin. All else as in that, hence the transverse lines stand out more distinctly. Rio de Janeiro, St. Catharina, Rio Grande do Sul.

ernestina. **E. ernestina** *spec. nov.* (47 f). Similar to *paeon*, but the shape is rounder, the distal margin but slightly undulate, not dentate, and above in addition to the anal spot of the hindwing a round black spot is present before the apex of the forewing, which is wanting in *paeon*. On the underside of the forewing the 2nd transverse stripe is not straight, but distally curved and here are placed 3 eye-spots, a black one with yellow iris and white pupil before the apex, and 2 smaller ones below it, consisting of brown rings with double, oval, silvery pupils. On the hindwing the transverse stripes are broader, the second is forked anteriorly and behind it are placed 5 eye-spots, of which those in cellules 2, 5 and 6 are black with white pupils, yellow iris and brown rings, whilst those in cellules 3 and 4 consist merely of brown rings with double, oval, silvery pupils. From Esperito Santo (Brazil).

Hermes Group.

ambigua. **E. ambigua** *Btlr.* (48 a). Above brown with 3 indistinct marginal lines, the proximal one dentate. Hindwing with ochre-yellow marginal line. Beneath lighter, the first transverse line irregular, the second curved round at the inner margin of the hindwing, the marginal lines as above. Both wings with 5 ocelli, which have brown rings and mostly double silvery pupils and on the hindwing are placed in an angular row. From Rio de Janeiro. — **modesta** *Btlr.* Similar to the preceding, somewhat larger, above brown, of the 3 marginal lines the proximal one is undulate. Beneath brownish grey with 2 oblique, but fairly straight, red-brown median lines. The marginal lines as above. Forewing with 3 ochre-yellow-ringed eye-spots, of which the first has a double silvery pupil. Hindwing with 5 ocelli, which have red-yellow rings and partly single, partly double silvery pupils. From Pará and Cametá (Amazons). — **huebneri** *Btlr.* is above quite like *ambigua*, beneath the ground-colour is more brownish at the base, more grey at the apex, ochre-coloured at the hindmargin. The median transverse lines are red-brown and the first is nearly straight. On the hindwing there is a 6th small eye-spot at the anal angle. Pará. — **benedicta** *Btlr.* is similar to *huebneri*, but differs in the larger eye-spots of the

under surface, the number of which BUTLER gives as 6 for the hindwing; some of these are black and some brown, the 4 middle ones have double white pupils, but all have yellow iris and outer brown rings, and the 2nd and 5th are larger than the others (in BUTLER's figure the 6th ocellus at the inner margin is absent). On the forewing there is a similar eye-spot before the apex and 2 obscure ones below it. The median bands are chestnut-brown and diverge somewhat anteriorly. From Sarayacu (Ecuador).

E. galesus *Godt.* Above brown, unspotted. Beneath likewise brown, with 3 dark brown transverse *galesus*, lines, 2 across the middle, 1 before the margin. The outer median line shaded with violet-grey at the distal side. The marginal line is undulate and before it is placed on the hindwing a row of 5 black dots. From Brazil. Whether the butterfly figured by BUTLER (in the Journ. Linn. Soc. Zool. Vol. 13, pl. 12, fig. 12) really belongs to this species is questionable, as the hindwing bears a row of 5 light-pupilled eye-spots instead of the dots.

E. melobosis *Capr.* (46 f). Above brown with a dark brown median line on the forewing and 3 marginal *melobosis*, lines on both wings. On the somewhat lighter under surface 2 transverse lines cross both wings, the first strongly curved, the second undulate on the forewing; between the two the ground-colour is darker. In the marginal area on the forewing 4, on the hindwing 6 small eye-spots, black with glossy white pupils and yellowish brown iris. From Chapeo d'Uvas (Minas Geraes). Flies in November.

E. umbrosa *Btlr.* Above according to its author's description greenish grey (but his figure is more *umbrosa*, blue than green) with 2 grey marginal lines on the hindwing. Fringes and body brown. Beneath lighter, white-dusted, traversed by 2 median stripes, 3 brown marginal lines, forewing with a small black ocellus before the apex; hindwing with 5 yellow-ringed eye-spots, the 2nd and 5th black with white pupils, the others brown. From Ecuador.

E. undulata *Btlr.* (48 a). Above brown. Beneath lighter, dusted with grey, the 2 median lines on the *undulata*, forewing more widely separated, posteriorly strongly dentate, the submarginal lines dentate, the other marginal lines almost straight. Forewing with 4 very indistinct, hindwing with 6 distinct small eye-spots, the 2., 4. and 5. with black central dot. From Pará.

E. mitchelli *French.* Size of the preceding species. Above brown. Beneath with indistinct median *mitchelli*, and marginal lines, forewing with 4, hindwing with 6 eye-spots in a straight row, which are placed somewhat further from the distal margin than in the allied species. These eye-spots are black, with yellow rings and blue pupils. Found in the states of New Jersey (near Lake Hopateong) and Michigan.

E. maimounè *Btlr.* Dark olive-brown. Hindwing in the posterior half with black submarginal line. *maimounè*, On the under surface the forewing is sprinkled with ochre-yellow scales, the median stripes rather broad, diverging towards the costa of the forewing, in addition there is a brown streak on the discocellular of this wing. The forewing has 5 eye-spots with light yellow rings, mostly without pupils, the hindwing 6 rather large eye-spots (the 2nd measuring 4 mm. in diameter) with red-yellow and outer brown rings, some of which touch the submarginal line, and the greater part with silvery pupils. From Pebas on the Upper Amazon (Peru); Costa Rica.

E. camerta *Cr.* Above brown. Forewing before the apex with a small eye-spot with yellow ring and *camerta*, silvery pupil. Under surface of the forewing with 4, of the hindwing with 6 similar ocelli of the same size, all with silver pupils, both wings with 2 brown, parallel median lines, curved on the hindwing, and with 3 marginal lines. From Surinam. GODMAN and SALVIN indeed unite this species with *hermes*, *sosybius* and *fallax*, but do not mention in their description the silver-pupilled eye-spot on the upper surface which STOLL distinctly describes in the 4th volume of CRAMER's work. Hence I regard *camerta* as a separate species.

E. hermes *F.* (= *sosybius* *F.*, *canthe* *Hbn.*, *nana* *Möschl.*) (48 a). Above unicolorous brown, without *hermes*, markings. Forewing beneath with 3—5 eye-spots, of which sometimes only the 2nd is distinct and the others are more or less obsolete. Hindwing with 6 ocelli, the 2 middle ones indistinct, the others black with brownish yellow rings, sometimes all distinct. The species varies very much and has a wide range of distribution, from New Jersey in the United States through Mexico, Central America, Colombia and Surinam to South Brazil, but occurs everywhere in different forms. FABRICIUS in his description of *hermes* has confused different species with one another, but as BUTLER states in the Proc. Zool. Soc. 1866 that he has compared the type of *hermes* and finds it identical with *canthe* *Hbn.*, and as he further declares in the Ent. Monthly Mag. 1870, p. 251, that *sosybius* *F.* is a synonym of *hermes*, the latter name must be accepted for the type-form. The early stages have been described in detail by EDWARDS. The egg is hemispherical, flattened at the base, with slight depression at the sides; greenish white. The young larva hatches 4 days after the egg is laid; it is white, with fine hairs, after the first moult light green, with a broad dark green longitudinal stripe across the back and narrower lateral stripes; between these stripes are placed rows of small white tubercles. Head rather large, anal extremity forked. The larva moults four times. After the last moult it is emerald-green with several yellow lateral stripes. Head covered with fine, raised, yellow dots. On grass. The pupa is suspended, short and thick, at the head obtuse, green, posterior part yellow-green with some black dots and a brown stripe. The butterfly appears in 14 days. In Mexico, according to EDWARDS, there are 2 generations. — **fallax** *Fldr.* (= *atalanta* *Btlr.*) (48 a) *fallax*.

is a form of *hermes* in which the median lines on the underside of the forewing converge towards the inner margin and on the hindwing are strongly angled. The number of eye-spots (3—5 on the forewing, 6 on the hindwing) agrees with *hermes*. From the Rio Negro, Venezuela, Pará. — **pimpla** *Fldr.* is a form likewise belonging here and only distinguished from *fallax* by the brown median lines on the underside of the forewing not converging, but diverging, towards the inner margin; the number of eye-spots is the same. From Rio Negro (Amazons).

— **narapa** *Schaus* is a further form of *hermes*, in which the outer median line on the underside of the forewing is distally shaded with white, and which has 4 ocelli on the forewing and 5 on the hindwing. From Castro in Parana (Brazil).

E. poltys *Prittw.* (48 a). Above grey-brown with 2 dark median lines and a short transverse streak on the discocellulars, an undulate submarginal and 2 marginal lines; the last-named 3 and the inner of the median lines are also continued on the hindwing. Between the marginal lines the ground-colour is lighter. One or two black, yellow-ringed spots at the anal angle. On the grey under surface the median lines are double and the outer one is distally accompanied by a brownish stripe, which extends from the costa of the forewing to the middle of the hindwing. Behind it 6 very small eye-spots. From Rio de Janeiro (Corcovado) and Rio Grande do Sul. — **binalinea** *Btlr.* (48 a) is a form of *poltys*, which only differs in the absence of the dark median shading at the distal side of the 2nd median line. From Venezuela and Brazil (Pernambuco).

E. eous *Btlr.* (48 a). Above olive-brown with a yellow-ringed dot at the anal angle of the hindwing and 3 dark marginal lines. Beneath light grey, the transverse lines very fine, angled, at the costal margin of the forewing curved basad, the outer one distally curved in the middle of the hindwing. Before the apex of the forewing 3 or 4 white dots, partly with dark margins, hindwing with 5 small black eye-spots, of which only the 2nd and 5th measure about 1—1½ mm., the 3rd and 4th are indistinct, but all have white pupils. From Brazil (Pará, Esperito Santo), Paraguay. — **zeredatha** *Btlr.* (48 a) is a form of *eous* in which all the ocelli on the underside are very small and punctiform. From Rio de Janeiro.

E. soter *Btlr.* Distal margin of the forewing almost straight, that of the hindwing undulate, the inner margin of the hindwing before the anal angle emarginate. Above olive-brown, a black spot on the transverse vein of the forewing, a straight transverse line behind the middle, a dentate submarginal line and 2 marginal lines brown, between the latter a brick-coloured line. Hindwing with 2 small eye-spots at the anal angle. Under surface reddish brown, sprinkled with dark brown, with a broad darker band, which runs from the middle of the costal margin on the forewing to the middle of the inner margin on the hindwing and is bordered at each side by a brown line. Forewing with a small silver-pupilled ocellus before the apex, hindwing with 6 small eye-spots in an irregular row, the 2nd and 5th with silvery double pupils, the 4th indistinct. Novo Friburgo (Brazil).

Phares Group.

E. phares *Godt.* (48 b). Above yellowish brown with a brown line behind the middle and 3 brown marginal lines, on the forewing in the ♂ with an eye-spot before the apex, in the ♀ with 2 or more eye-spots, hindwing with 5 or 6 in both sexes, of which the 2nd and 5th are large, black with double white pupil and red-yellow ring, the others mostly obscure and indistinct. On the under surface the forewing is reddish yellow with yellowish grey marginal area, the hindwing yellowish grey with 2 brown, more or less curved median lines, the eye-spots more distinct than above and all with white, sometimes silvery pupils. Argentina (Entrerios, Cordoba), South Brazil, Venezuela. Not rare. Varies in the number of the eye-spots on the upper surface, examples occurring which above have no ocelli at all on the forewing and others which have only 2 on the hindwing. — A similar form has been described and figured by BURMEISTER under the name **spartaeus**. It has one eye-spot on the upperside of the forewing and 2 on the hindwing. The latter has on the under surface 6, the forewing 3 comparatively small eye spots, the two largest measuring little more than 1 mm. They are all black with yellow ring and white, sometimes double pupils. BURMEISTER has only described the ♀, which has an expanse of 40 mm. From Entrerios.

pharella *Btlr.* (48 d) is a smaller form of *phares*, which has an expanse of only 28 mm. Above unicolorous olive-brown without eye-spots. Under surface of the forewing ochre-yellow, with distal margin grey, and with 3 ochre-yellow-ringed eye-spots with violet pupils. Hindwing grey, the median lines almost straight, behind the distal one a whitish stripe with 4 yellow-ringed ocelli in cellules 2—5, the 2 distal ones black with white pupils, the others brown with violet pupils. From Rio de Janeiro. — **pharnaces** *form. nov.* (48 b) is a further form of *phares*, in which the brown stripes in the basal half of the hindwing beneath are darker and strongly dentate, moreover the median line on the underside of the forewing is not straight, but forms a wide curve distad. From South Brazil.

E. innocentia *Fldr.* (48 b). One of the smallest species. Above unicolorous brown. Beneath likewise brown with 2 somewhat curved transverse lines before and behind the middle, behind the 2nd on the hindwing a light stripe, in the marginal area on the forewing 3 or 4, on the hindwing 5 or 6 ocelli, with white pupils and yellow and brown rings. From Venezuela.

E. numilia *Fldr.* (48 b). Above light brown, forewing with a straight dark transverse line behind the middle, hindwing with 2 such lines and 2 distinct eye-spots at the anal angle and 3 indistinct ones above them. Beneath yellowish grey-brown with 2 fairly straight median lines, 5 obscure eye-spots on the forewing and 6 distinct ones on the hindwing with yellow and brown rings and white pupils, the 5th somewhat larger with double pupil. From Muzo, to the north-west of Bogotá (Colombia).

Harmonia Group.

E. gulnarè *Btlr.* (48 b). Above unicolorous brown. Beneath likewise brown, only at the inner margin *gultuari*, of the forewing somewhat lighter, with 2 dark brown median bands, on the forewing nearly straight, on the hindwing somewhat curved. The submarginal line is characterized by its forming 2 small curves in each cellule on both wings, whilst in most species there is only 1 curve in each. In the number of the eye-spots and dots the two figures of this species hitherto published differ, although they are drawn from the same example. BUTLER figures on the forewing 5 eye-spots and 2 dots above them, on the hindwing 6 eye-spots, whilst GODMAN and SALVIN figure only one eye-spot on the forewing and 5 on the hindwing. All the eye-spots are without the yellow rings. The example figured here has on the forewing 3 white dots, the middle one finely margined with black, on the hindwing 5 eye-shaped, round black spots, of which only the 1st, 2nd and 5th have white pupils. BUTLER's example came from Panama (coll. SALVIN), the one figured here from Mapiri (coll. BANG-HAAS). STAUDINGER (*i. l.*) had named it *civica*.

E. jovita *Fldr.* (47 f). Above unicolorous brown. Inner angle of the hindwing obtusely produced. Beneath *jovita*, with 2 nearly straight darker median lines, the 2nd curved round basad before the inner margin of the hindwing, behind it a much lighter stripe, especially on the hindwing, and on the forewing 3—4, on the hindwing 5 ocelli, of which on the forewing the posterior one, on the hindwing the 3rd and 4th are indistinct. From Colombia (Bogotá, Rio Agna Valley). September.

E. harmonia *Btlr.* (48 b). Above likewise unicolorous brown. Under surface of the forewing brownish *harmonia*, grey, of the hindwing light grey, so that the undulate transverse lines stand out distinctly. Forewing with 4, hindwing with 5 or 6 eye-spots, of the former only the 2nd, of the latter only the first 2 and last 2 distinct. From Ecuador (Quito) and Colombia (Mount Quindiu, 2100 m.). October.

E. phineus *Btlr.* (= *eugenia* *Fldr.*) (48 b). Above unicolorous brown, beneath much darker than *har-* *phineus*. *monia*, the median stripes broader. Forewing with only one eye-spot. Hindwing with 6 ocelli, of which those in cellules 3 and 4 also stand out distinctly, all having white, some of them double pupils. From Cuzco in Peru, the Songo in Bolivia, and Venezuela.

E. calixta *Btlr.* (= *cucullixta* *Stgr. i. l.*) (48 c). Above dark olive-brown. Beneath lighter, the median stripes *calixta*, on the forewing nearly straight, diverging anteriorly, on the hindwing the outer one bicurved and before the inner margin angled. Forewing with 5 eye-spots with silver pupils and yellow rings, the 2nd larger, the 3rd and 4th small, hindwing with 6 similar eye-spots, the 2nd connected with the 3rd, the 1st, 3rd and 4th small, the 2nd large. From Bogotá. — **cucullina** *form. nov.* (48 c) is a form of *calixta* in which the eye-spots on the underside *cucullina*, of the hindwing are of almost equal size, only the first and last are smaller and the black ring of the 2nd is somewhat broader. From Choco (Colombia).

E. alcinoë *Fldr.* (48 c). Above unicolorous brown. Beneath grey-brown, the median lines nearly straight, *alcinoë*. Forewing with 4, hindwing with 5 eye-spots in a somewhat angled row, of which the first on the forewing and the 2nd and 5th on the hindwing are larger. From Colombia and Venezuela. Our figure from FELDER's type in the Tring Museum.

E. yphthimia *Fldr.* (48 c). Wings rather rounded, above brown with an eye-spot at the anal angle. Be- *yphthimia*. neath the marginal area of the hindwing is lighter than the rest of the ground-colour and the submarginal line runs almost as straight as the marginal lines. Forewing with one or more indistinct eye-spots, hindwing with 5 eye-spots of equal size with double white pupils. The ♀ has further on the upper surface 2 black blind spots on each wing. From Bahia and Bolivia. Figure from one of FELDER's types. — **pacta** *form. nov.* (48 d) is a *pacta*, form of *yphthimia* which differs in the somewhat undulate distal margin of the hindwing, and in the larger and more numerous eye-spots on the under surface. Moreover the pupils in these eye-spots are single, but much larger, and some of them silvery. The forewing has 4, the hindwing 6 eye-spots, the 2nd and 5th larger than the rest. From Cuyaba in Matto Grosso (Brazil). Coll. BANG-HAAS.

E. nebulosa *Btlr.* (48 d). Above olive-brown, without eye-spots, only with the 3 marginal lines. Beneath *nebulosa*, little lighter, the median lines on the forewing fairly straight, on the hindwing finely denticulate, the former with one small eye-spot, the latter with 5 ocelli, all with white pupils and yellow rings, the 2nd and 5th large and black, the rest brown. From Venezuela, Peru, Bolivia.

E. perfuscata *Btlr.* (48 d). Above likewise unicolorous olive-brown only with the 3 darker marginal *perfuscata*, lines. Beneath somewhat lighter and somewhat tinged with violet, the median lines nearly straight, only the distal one curved round basad at the inner margin of the hindwing. Marginal area somewhat lighter, on the forewing 4, on the hindwing 5 ocelli, some brown, others black, some with one, others with 2 pupils. From Pará and Esperito Santo (Brazil).

E. sylvina *Fldr.* (48 c). Upper surface brown, the submarginal line placed somewhat further from the *sylvina*, marginal lines than usual. Beneath somewhat dusted with violet, the transverse lines very fine, the submarginal line as above, strongly dentate, the forewing with one, the hindwing with 5 small eye-spots, the 3rd and 4th indistinct. From Bahia (Brazil) and Cuzco in Peru. Figure from FELDER's type.

E. numeria *Fldr.* (= *historic* *Stgr. i. l.*) (48 c). A small species. Above brown, beneath little lighter *numeria*.

with 2 straight, fine dark brown median lines. The marginal area lighter with the 3 marginal lines and 5 ocelli on each wing, all small and of uniform size, yellowish brown with small black centres finely pupilled with white and surrounded by brown rings. From Bahia. Figure from FELDER's type.

manasses. **E. manasses** *Fldr.* (48 c). Above brown, hindwing with 2 black eye-spots in red-yellow rings and with pale-coloured pupils, the outer large, a third, indistinct, above them. Under surface dark to the 2nd straight transverse line, marginal area lighter, especially on the hindwing. Forewing without eye-spots, hindwing with 6 small ones in an angled row. From Bahia. Figure from FELDER's type.

mimas. **E. mimas** *Godm.* (48 d). A larger species. Similar to the preceding, but the wings broader and the distal margin of the forewing less rounded, also the hindwing with somewhat stronger excisions. Above brown with 2 eye-spots at the anal angle of the hindwing, the larger in cellule 2 with double white pupil and yellow ring, the smaller in cellule 1c with single pupil. Beneath yellowish brown, strongly sprinkled with dark brown; 2 straight brown median lines, enclosing a darker median area. In the lighter marginal area are placed on the hindwing 6 ocelli, mostly bi-pupilled, the 3rd removed somewhat proximad and occasionally double. From Corvico in Bolivia.

oreba. **E. oreba** *Btlr.* Size of the preceding species, the forewing more pointed, above unicolorous brown, without eye-spots. Beneath somewhat lighter, distally dusted with grey, the dark brown median lines on the forewing somewhat curved, as also the inner line on the hindwing, while the outer forms a short angle on each vein and crosses the extremity of the cell. The submarginal line on both wings forms 2 small lunules in each cellule with their concavity towards the base (as is also the case in *gularè*). On each wing 5 eye-spots, the 1st, 2nd and 5th black with yellow iris, the others ochre-yellow, all with white pupils. In addition there are at the anal angle of the hindwing two very indistinct eye-spots in cellule 1 b. The locality of this species is unknown. BUTLER described it from an example in coll. KADEN (now Mus. DRUCE).

eremita. **E. eremita** *spec. nov.* (48 d) is like *oreba* *Btlr.* in size and shape, but shows essential differences in the scheme of markings on the under surface. The ground-colour of the underside is darker, less sprinkled with grey. The 2nd transverse line does not intersect the end of the cell on the hindwing, but passes round it at some distance in a curve, forming a proximally concave crescent in each cellule. The submarginal line in its whole course on both wings likewise forms only one crescent in each cellule, whilst in *oreba* it forms two in each. The forewing has 4, the hindwing 5 ocelli. — From Marcapata in Peru (coll. BANG-HAAS).

obscura. **E. obscura** *Btlr.* Above unicolorous brown, beneath likewise brown, the transverse line beyond the middle is irregularly curved and dentate, at the inner margin of the hindwing it unites with the submarginal line, which forms only one crescent in each cellule. On the forewing there are 3 small white dots before the apex, on the hindwing 5 eye-spots, the 2nd and 5th black with yellow iris and white pupil, the rest entirely filled up with brownish ochre-yellow and of a reniform shape. Of these only the one placed at the costal margin has a white pupil. Size 53 mm. From Bolivia.

Necys Group.

necys. **E. necys** *Godt.* (= *vastata* *Btlr.*, *Tayg. neonympha* *Fldr.*) (48 d). Wings rounded. Above unicolorous brown. Beneath finely dotted with darker, with strongly dentate median lines, a similar submarginal line and 5 or 6 fine white dots on each wing in the marginal area. From Brazil (Rio Grande), Colombia (Rio Agna Valley, 1600 m., Quindiu Pass, 2500 m.). — **E. rustica** *Btlr.* (? = *Tayg. anophthalma* *Fldr.*) (47 g). A form of *necys* in which on the underside of the forewing there is a small white spot beside the first white dot and the other white dots on the forewing are absent, but all are present on the hindwing. From Bolivia and Huamboya in Ecuador. — In **E. fabiana** *Btlr.* the median lines are not dentate, but only weakly curved and the white spot at the costal margin of the forewing of *rustica* is wanting. From Macabe in the province of Rio de Janeiro.

polyphemus. **E. polyphemus** *Btlr.* (47 g). Above unicolorous brown, beneath but little lighter, the outer median line is on the forewing twice, on the hindwing several times angularly bent proximad. Forewing with 3 small white dots before the apex; hindwing with 4 or 5 extremely small and one large, distinct black eye-spot before the anal angle, the latter and some of the former with white pupils. From Colombia (Bogotá, Carmen), Bolivia. — **E. cyclops** *Btlr.* (= *umbracea* *Btlr.*) (47 g) is a form of *polyphemus*, in which on the under surface the outer median line of the forewing is not angled, but forms only a slight curve. Moreover on the hindwing the single small lunules of this line run in a straighter direction. The black ring of the eye-spot in cellule 2 of the hindwing is very broad. From Panama, Costa Rica, Peru, Ecuador.

quantius. **E. quantius** *Godt.* (= *morima* *Schaus*) (47 g). Above unicolorous brown. Beneath likewise brown, with 2 darker almost straight parallel transverse lines across the middle of both wings, enclosing a median area somewhat dusted with violet-grey. Submarginal line on both wings strongly undulate, the distal margin dusted with violet-grey. 6 fine yellowish white dots on the hindwing and 4 or 5, somewhat finer still, on the fore-

wing. From South Brazil (Parana). — *stelligera* Btlr. is a form of *quantius* in which the anterior white dot on the underside of the hindwing is somewhat larger. From Parana and Esperito Santo.

E. eusebia Btlr. (47 g). Above olive-brown, with the distal margin darker. Beneath lighter in the marginal area. Of the median lines only the anterior half of the outer line is visible on the forewing, on the hindwing the inner median line is almost straight, the outer undulate. Before the apex of the forewing a white dot surrounded with dark. On the hindwing 5 or 6 similar eye-shaped dots. The submarginal line forms shallow lunules on the forewing, deeper ones on the hindwing. From Colombia (Bogotá), Antilles (coll. BANG-HAAS).

E. boliviana Godm. (47 g). Above olive-brown. Beneath the forewing is olive-brown, with the distal margin broadly ochre-yellow, proximally to which are placed 2 or 3 white subapical dots. An undulate submarginal line and 2 straight marginal lines brown. The hindwing is strongly dusted with white in the posterior half, the distal margin dull ochre-yellow, the base brown, 2 very dentate median and an undulate submarginal line dark brown. In the marginal area a row of fine white dots. Bolivia (San Jacinto, Corvica).

E. griseola spec. nov. (47 g). Above grey-brown, costal and distal margin darker, hindwing lighter, marginal lines indistinct. Under surface yellowish grey, in the marginal area lighter, the first transverse line indistinct, the second more strongly dentate on the hindwing than on the forewing, the submarginal line dentate on both wings, the marginal lines on the forewing straight, on the hindwing undulate. In the marginal area on the forewing 5 brown spots, the 3 middle ones with silvery pupils, hindwing with 5 ocelli with silvery pupils and ochre-yellow and brown rings. From the Mapiri.

E. griseldis spec. nov. (48 d) ♀. The distal margin of the hindwing is strongly dentate, the inner margin excised. Above grey-brown, the distal half of the hindwing lighter. No first transverse line discernible. The 2nd transverse line is placed on both wings somewhat further distad than usual and is fairly straight. Submarginal line dentate, 2 marginal lines dark, a black dot in cellule 2 of the hindwing. Under surface yellow-grey, inner margin of the forewing and distal half of the hindwing lighter, finely sprinkled all over with brown, forewing with the same transverse lines as above, hindwing with a straight first transverse line, the 2nd transverse line widened into a broad brown band, in the light marginal area 3 black dots, in part with double white pupils and some brown spots between them. From Esperito Santo (Brazil).

E. muscosa Btlr. (48 e) ♀ has the apex of the forewing truncate, so that an obtuse angle is formed in the distal margin at vein 5 and a right angle at the costal margin; in the ♀ figured this point is even somewhat produced. Hence the species forms a transition to the genus *Pindis*. Above unicolorous olive-brown. On the under surface the forewing is lighter brown and irrorated all over with dark brown. The ground-colour of the hindwing is more bluish grey, likewise irrorated with brown, bearing in the middle a blue-grey spot with less irroration, behind this a broad blue-grey band without any; but in the ♀ this band is also irrorated. — According to W. MÜLLER the egg of this species is round, without markings. The young larva resembles that of *Taygetis ypthima*. The body is whitish green, adorned with fine bristly hairs, the head light brown, rugose, with conical elevations, on which are placed short black-brown horns with bristly hairs. The larvae feed on grasses, but died before the first moult. The butterfly is distributed in South Brazil (Blumenau, Joinville, São Paulo).

E. antonoë Cr. (48 e). One of the largest species. Above brown with 2 dark marginal lines on the forewing and 3 on the hindwing, also a small, black, oval spot in cellule 2 of the hindwing. Beneath lighter brown, with 2 almost straight brown median stripes, 3 eye-spots on the forewing, only the first distinct, 5 on the hindwing, the 2nd and 5th large, the others smaller, all in red-yellow rings. From Guatemala, Honduras, Nicaragua, Panama, Venezuela, Surinam, Amazons. — *zeba* Btlr. is a form of *antonoë* with the under surface lighter brownish grey, the median bands somewhat narrower and converging somewhat towards the anal margin of the hindwing. From Pebas in Peru.

E. sabina Fldr. (48 e) is somewhat similar to *antonoë* Cr., but considerably smaller. The upper surface is grey-brown with 3 faint transverse stripes, which are broader on the hindwing, a large black eye-spot with yellow and brown rings in cellule 2 of the hindwing before the anal angle and 2 similar, somewhat obscure eye-spots at the apex of the same wing; the other 2 eye-spots of the underside only show through quite faintly above, the under surface is lighter, with one ocellus on the forewing and 5 on the hindwing. From the Amazons and Cayenne. The figure is from FELDER's type in coll. ROTHSCHILD.

E. lineata Godm. (45 e). The hindwing of this species is more elongate than in *antonoë*, with the anal half of the distal margin dentate. The upper surface is unicolorous brown, the under surface somewhat lighter brown, with a straight, yellowish white, sharply defined median band 1 mm. in breadth and a narrow, brown, white-edged basal line. On the broad distal margin, which is much lighter, the dentate submarginal line and the marginal line stand out distinctly. Each wing bears 2 or 3 small, black, white-pupilled eye-spots. The median band varies greatly in shape, width and colouring. From Manaure in the Sierra Nevada, from Santa Marta (900 m.) in North Colombia, Carmen (1200 m.) in West Columbia, in August. — I propose the name *interrupta* form. nov. for a form in which the median band on the underside of the forewing is only indicated at the costal margin by a pointed white triangle, being otherwise replaced by a dark brown line, accompanied distally in

places with white scales. On the hindwing it is interrupted several times, only remaining visible, as a fine, white transverse line, at the costal margin, in the middle of the wing and before the anal angle. On the other hand the first transverse line (that nearest to the base) is on both wings distinctly white and distally margined *melania*, with brown. — *melania* *form. nov.* differs still more. In it the white median band has disappeared entirely and in its place a black line runs through the deep dark brown ground-colour. The basal transverse band is also much darkened, so that it is inconspicuous. The eye-spots and the broad, light marginal band, however, are as in the type-form. Both forms were found by FASSL at Carmen in West Colombia, *interrupta* at 1600 m. in December, *melania* at 1200 m. in October.

satyrina. **E. satyrina** Bates (= Tayg. cecilia Bdv.) (48 e). Above brown with a black, white-pupilled, sometimes very indistinct eye-spot at the anal angle of the hindwing. Beneath likewise brown with 2 parallel, nearly straight, dark brown transverse stripes crossing the middle of both wings, the inner one distally, the outer one proximally bordered with ochre-yellow. The distal margin of the forewing is rather broad, lighter reddish brown, and shows before the apex a small black, white-pupilled ocellus. The hindwing has anteriorly two and posteriorly one similar but larger ocellus. The species is very variable. From Guatemala, Costa Rica, Panama *incerta*, and Mexico. — *incerta* Btlr. is a form of *satyrina* which differs in the lighter brown ground-colour of the under surface and has 5 eye-spots on the hindwing beneath. Occasionally the 3rd and 4th of these eye-spots are small, but all have distinct white pupils. There are further 2 white dots on the forewing. Occasionally also the ochre-yellow bordering of the brown median stripes is absent. A ♀ of this form has on the upperside of the forewing a reddish yellow-brown band, differing somewhat from the ground-colour, and on the underside of the hindwing only two eye-spots in cellules 2 and 5. Between these are placed in cellules 3 and 4 three small *gigas*, white spots. From Costa Rica. — *gigas* Btlr. (48 e) is a rather large form of *satyrina*, in which the forewing has 3 ocelli on the under surface (one larger and 2 smaller) and the hindwing five large ones, the first, second and last black, with yellow iris and white pupil; the third and fourth are brown with white pupil. From Mexico.

tiessa. **E. tiessa** Hew. Size of the preceding. Above dark brown with black submarginal line. The hindwing is dentate and has in the anal angle an indistinct eye-spot with brick-red ring. The under surface (according to HEWITSON) is brown from the base to the middle. Both wings are traversed before the middle by a red-brown band, and at the middle by a broader band of the same colour. Then follows a broad grey band, on which is placed a brown stripe with the eye-spots; these consist of a small one near the costa of the forewing and 3 on the hindwing, namely 2 at the apex and 1 at the anal angle. All the eye-spots are black with reddish iris, dark brown ring and white pupil. 2 submarginal stripes and the margin red-brown. The stripe on the hindwing is dentate like the margin. — The figure in BUTLER Lepid. Exot. pl. 18 fig. 4 does not agree with this description of HEWITSON's as regards the ground-colour of the wings and the colouring of the eye-spots. According to this figure the ground-colour of both wings is light reddish grey or flesh-coloured all over with a lilac band beyond the middle, whilst HEWITSON says the basal half of the wings is brown and the band grey. The iris of the eye-spots according to BUTLER is light yellow, HEWITSON calls it rufous. GODMAN and SALVIN describe the species with 5 eye-spots on the hindwing, of which 2 are indistinct. From Nicaragua, Costa Rica, Panama and Ecuador.

libye. **E. libye** L. (= harpyia Fldr.) (48 e). Above olive-brown with two dark brown marginal lines and one submarginal line, beneath much lighter, more or less inclining to lilac, with 2 straight, rust-brown stripes, one before, the other in the middle; the former crosses the cell on both wings, the latter on the forewing only touches its posterior angle, on the hindwing it enters the cell at the point of origin of vein 5 and leaves it between that of vein 2 and that of vein 3. Before the apex of the forewing a small round ocellus, 5 oval ocelli on the hindwing, of which the 1st, 2nd and 5th are black with very indistinct pupils and yellow ring, thickened at the proximal side, the rest indistinct. *libye* is a common and widely distributed species. Guatemala, Honduras, Nicaragua, Costa Rica, Panama, Colombia, Ecuador, Surinam, Brazil (Pará, Pernambuco, Bahia, Rio), Jamaica. *libyoidea*, — *libyoidea* Btlr., is a form of *libye*, somewhat larger, with the forewing more produced at the apex and the hindwing less strongly dentate. On the under surface are placed on the forewing four distinct black-brown eye-spots with yellow rings and with white pupils formed of irregular white dusting, the ocelli of the hindwing are much larger than in the type-form, the largest, in cellule 2, measures 6 mm. in length and 4 mm. in breadth. In the course of the 2nd (outer) median stripe I notice another difference from *libye*, which BUTLER has not mentioned. In the figure of *libyoidea* in the Proc. Zool. Soc. Lond. 1867 pl. 11 fig. 13 this stripe intersects the lower angle of the cell on the forewing, whilst in *libye* it only touches it. On the hindwing it enters the cell between the points of origin of veins 4 and 5, thus on the lower discocellular, and leaves it between veins 3 and 4, whilst in *libye*, as mentioned above, it enters the cell at the origin of vein 5 and leaves it between veins 2 and 3. *gracilis*, From Nicaragua. — *gracilis* *form. nov.* (48 f) is a further form of *libye*, differing chiefly in having the two straight, reddish brown median stripes on the under surface of both wings placed more distally. On the forewing the 2nd, outer stripe is situate at a distance of 2 mm. from the cell. On the hindwing it crosses the lower discocellular as it enters the cell and the median at the origin of vein 3 as it leaves it, and is thus placed somewhat further distad than even in *libyoidea*. In consequence of this *gracilis* has the marginal area much narrower. On the fore-

wing there is only one eye-spot, the 5 eye-spots of the hindwing are smaller, less oval, but coloured like those of *libye*. From Pebas in Peru. Coll. BANG-HAAS.

Pacarus Group.

E. saundersii *Btlr.* The inner angle of the forewing with a bluntly angled projection. Above brown *saundersii*, with 2 indistinct marginal lines. Beneath lighter brown, inclining to violet, the marginal area of the hindwing bluish green. Two brown median lines, diverging towards the costa of the forewing, the outer forming a small angle distad on the hindwing. Two brown marginal lines, forewing without eye-spots. On the hindwing 5 (occasionally 6) oval black eye-spots with light brown and outer dark brown rings and silvery pupils. The 3 middle ones are somewhat larger than the rest. Size 56 mm. From Ega on the Amazon and from Pernambuco.

E. mima *Btlr.* Similar to the preceding, but much smaller, only measuring 37 mm. On the under sur- *mima* face the forewing has a small eye-spot before the apex and the median lines are more approximated anteriorly; the hindwing is less violet and its eye-spots are smaller and placed nearer to the margin. From Tapajos.

E. fumata *Btlr.* Above black-brown, with light brown marginal line. Beneath somewhat lighter; on *fumata*, the forewing only one median line is present, which touches neither the costal nor the inner margin; on the hindwing there are two, of which the outer one is angled at the anal angle and joins the undulate submarginal line. In addition there are 2 dark brown marginal lines. Hindwing with 6 heart-shaped black ocelli, which have ochre-yellow rings and outer dark brown ones and are sprinkled with steel-blue dots, the 3rd, 4th and 5th ocelli somewhat larger than the rest. 55 mm. From Rio Grande.

E. amalda *spec. nov.* (48 f). This new species is similar to *fumata* beneath, but very different above *amalda*, and considerably smaller. The basal and median areas of the forewing above are velvety dark brown, the costal and distal margins lighter brown. This lighter colouring begins narrowly at the base of the costal margin, but gradually increases in breadth distally and measures 4 mm. from the apex to the inner angle, where it again becomes somewhat narrower. At the base the two colours shade into one another. The hindwing is lighter brown. The under surface is dark grey-brown with 2 median, one submarginal and 2 marginal lines brown. The forewing has no eye-spots, but on the hindwing there are 5 small, proximally pointed, black ocelli, which are surrounded by brown rings and have obliquely placed pupils formed of silvery dusting. From the Mapiri (Amazons), coll. BANG-HAAS.

E. pacarus *Gott.* Above unicolorous brown. Beneath the same with 2 darker marginal lines, the hind- *pacarus*, wing in addition with a dark brown median line and 5 round, deep black ocelli, which have a pupil composed of silvery dusting, a brownish iris and outside it a dark brown ring. On the forewing there are no eye-spots. 50 mm. From Brazil. Rare, apparently wanting in all the more recent collections.

E. peculiaris *Btlr.* Above brown with a lighter line before the margin and a black-brown marginal *peculiaris*, one, the hindwing with a dentate submarginal. Beneath lighter, both wings with 2 dark brown marginal, a dentate submarginal and 2 irregular median lines. A washed-out light brown band crosses the middle. The hindwing has before the apex at the costal margin 2 obliquely placed, black, white-pupilled ocelli with ochre-yellow iris. The species is easy to recognize by these 2 isolated eye-spots on the under surface. 53 mm. From Minas Geraes. Rare.

E. insignis *Btlr.* Above brown with 2 indistinct marginal lines, on the hindwing the larger eye-spot *insignis*, of the under surface before the anal angle shows through above. Beneath the wings are lighter, the hindwing whitish in the median area; both wings with 2 brown marginal lines, the inner on the hindwing undulate. The hindwing with 2 fairly straight, parallel brown lines, only 3 mm. apart, through the middle and in the marginal area, in cellules 1 c, 2 and 3, with 3 black, silver-pupilled eye-spots, which have a common ochre-yellow bordering and of which the middle one is large, the others very small. Locality unknown. Collected by BATES.

E. erichtho *Btlr.* (= *antonina* *Fldr.*) (48 f). The inner angle of the hindwing is obtusely produced as *erichtho*, in *saundersii*. Upper surface olive-brown, the forewing with 2, the hindwing with 3 dark brown marginal lines. Beneath lighter brown; the margins dusted with whitish violet, with 3 distinct marginal and 2 dark brown median lines, and with a short dark brown streak on the discocellular of the forewing. Two small eye-spots before the apex of the forewing, occasionally also a third in cellule 2; hindwing with 6 black eye-spots with thick, glossy white pupils, which are surrounded by 4 rings, first a brownish yellow, then a black, then ochre-yellow and outside again black. The 3rd, 4th and 5th eye-spots are usually larger than the rest. From Cayenne, Surinam, Brazil (Rio, Pernambuco, Bahia, Pará, Ega), Bolivia (Coroico).

Batesii Group.

E. batesii *Btlr.* (= *terentia* *Fldr.*) (48 g). Above brown, with a slight lilac gloss, with 3 indistinct mar- *batesii*, ginal lines and grey fringes. The ♀ at the anal angle of the hindwing with a black oval spot with white pupil

- and a light brownish ring. Beneath light lilac with 2 red-brown median and a short, oblique basal stripe, a similar band in the marginal area, on which the eye-spots are placed, and 3 marginal lines. On the forewing a black eye-spot before the apex, with ochre-yellow ring and glossy white pupil, and some silver dots below it. Hindwing with 5 ocelli or eye-shaped spots, of which the 1st, 2nd and 5th resemble the eye-spot on the forewing, but the 2nd and especially the 5th are much larger, whilst the 3rd and 4th are composed only of silver spots with red-brown bordering. From Surinam and the Tapajos. In the Surinam examples the inner margin of the forewing is somewhat ochre-yellow on the under surface. — *analís* Godm. (48 f) is a form of *batesii* with a slight purple suffusion above and a distinct spot of dark blue scales at the anal angle of the hindwing. The red-brown bands on the under surface are broader and show through above; otherwise not different from *batesii*. From São Paulo and the Tapajos (Amazon) and from Pebas in Peru. — The form *tersa* Stgr. i. l. (49 a) is quite similar to *batesii* on the upper surface, but on the underside, instead of the 2 or 3 silver spots which *batesii* and *analís* have between the eye-spots of the hindwing, bears 2 further small brown eye-spots with grey pupil, yellow iris and dark brown outer ring. In addition there is also a quite small, but otherwise similar black ocellus at the anal angle of the hindwing; so that there are 6 eye-spots altogether on this wing. Locality unknown. Coll. BANG-HAAS. — *thalessa* Möschl. is according to its author's figure a form of *batesii* which only differs in having a small black eye-spot with white pupil, placed in cellule 3 on the hindwing between the two large eye-spots. But in the corresponding description the eye-spot is not mentioned, the cellule in question, on the contrary, being described as without eye-spot. From Surinam.
- juani*. **E. juani** Stgr. (49 a). Above dark brown-grey, with only the anal eye-spot of the hindwing showing through somewhat above. The under surface is similar to that of *batesii*, but the ground-colour in the basal part to the 2nd transverse stripe is much darker, brownish grey. The whitish grey ground-colour is confined to the distal half of the wings. The 2 dark brown median stripes are broad, straight and parallel. The submarginal line is rather broad, not dentate but almost straight. On the broad brown band in the marginal area are placed on the forewing one eye-spot, on the hindwing 5 black ocelli, of which the 5th is very large and with single white pupil, the 1st and 2nd small with double pupil, whilst the 3rd and 4th bear in the middle oblong silver streaks. All are margined with ochre-yellow. From the Rio San Juan in West Colombia.
- tricolor*. **E. tricolor** Hew. (49 a). One of the most beautiful species of the genus. Above the forewing is brown, the costal margin reddish brown; a glossy blue line runs parallel with the posterior part of the distal margin. The hindwing is black-brown with a broad red-yellow costal margin and a glossy blue stripe along the inner margin and the posterior part of the distal margin. Beneath light violet-grey with 2 broad brown median stripes, a narrow oblique stripe at the base of both wings, a broad vague band in the marginal area, on which the eye-spots are placed, and 3 smooth marginal lines running parallel with the distal margin. On the forewing one eye-spot before the apex, on the hindwing 3, as in *batesii*, in cellules 2, 5 and 6, but the first very large and all with double pupils and between them in cellules 3 and 4 several elongate silver streaks placed in 2 oval brown spots bordered with red-yellow. From Fonteboa, Tapajos (Amazons). — The form *fulgora* Btlr. (49 a) is distinguished by a bright iridescent blue stripe, which on the upper surface of the forewing extends from the base across the cell, widens before the apex in all the cellules and is then continued as a narrow line along the distal margin to the inner angle. From Pebas in Peru and from Coca in Ecuador.
- nortia*. **E. nortia** Hew. (49 a). ♂ above yellowish white with the costal margin of the forewing and the distal margin of both wings brown, the brown bands of the under surface also showing through above. Under surface white, with 2 broad, parallel, brown median stripes and in the marginal area a broad brown band, which on the forewing contains no eye-spots. On the hindwing instead of this band 2 small eye-spots at the apex, 2 at the anal angle (one very large), all black with white pupils and red-yellow and brown rings and between those in cellules 3 and 4 two lead-coloured longitudinal streaks in red-yellow and brown oval spots. At the distal margin 3 brown marginal lines, which on the hindwing are somewhat undulate. The ♀ is grey-brown above, towards the distal margin darker, the median stripes of the under surface show through above. Beneath the markings are similar to those of the ♂, but the basal and median areas are finely dusted with brown as far as the 2nd (somewhat basally curved) median band, so that only the distal part retains the light ground-colour. The ocelli and silver spots, however, are as in the ♂. From Pebas (Peru), the Tapajos (Amazons) and Cayenne.
- nobilis*. **nobilis** form. nov. (49 a) is a second ♀-form of *nortia*, in which the distal half of the forewing above is light whitish grey and the basal half, the whole costal margin and 2 marginal lines brown. The light colouring is continued also on the hindwing at the apex for a short distance, but then gradually shades into the brown ground-colour. On the under surface the 2nd brown median stripe is not curved but straight and the light band beside it considerably narrower. The eye-spots are as in the type-form. From Tabatinga on the Amazon.
- moderata*. **moderata** form. nov. (48 g) is another female form of *nortia*, in which the light band on the under surface is likewise quite straight on both wings behind the middle. But the upper surface of both wings is entirely brown, as in the ♀ of the type-form, and has 3 dark brown marginal lines. From the Mapiri (Bolivia).
- segesta*. **E. segesta** spec. nov. (51 b). ♂. The upper surface is unicolorous brown with 3 brown marginal lines, which on the forewing are indistinct. The under surface is similar to the ♀♀ of *E. nortia*, but distinguished by the different position of the white median band. This band on both wings is placed *between* the two brown

bands, whilst in *nortia* ♀ it is placed distally to the second brown band. Hence the marginal area is broader than the basal, especially on the hindwing. The brown bands are broader than in *nortia* — but the eye-spots quite as in that form, the oval ochre-yellow spots, however, each with a glossy silver streak in the middle, stand out distinctly between the eye-spots. Only the ♂ has yet been found. From Gramal near Muzo in Colombia (FASSEL).

E. lesbia *Stgr.* Above light brownish grey with 3 straight brown transverse stripes on the forewing *lesbia*, and 2 on the hindwing and 3 brown marginal lines. Hindwing with black anal eye-spot with double white pupil and broad ochre-yellow ring; before this an elongate white spot and towards the apex 3 round black spots, of which the middle one is the largest. The under surface is almost the same, except that a small eye-spot is placed before the apex of the forewing and a few silver spots below it; there is also a large ochre-yellow spot proximally to the anal ocellus on the hindwing and at the apex of this wing a second eye-spot instead of the black spot, while the white longitudinal streak on the upper surface is absent. 41 mm. From the Amazons (Massauary, Teffé, Fonteboa).

Gera Group.

E. gera *Hew.* Above dirty white, forewing at the costal and distal margins broadly brown, hindwing *gera*, bearing before the middle 2 brown lines and before the margin 2 indistinct eye-spots with dark central dots, both wings with 2 brown marginal lines. The under surface is as above, only the forewing also has 2 brown lines before the middle, the eye-spots of the hindwing are reddish, have black dots with white pupils, distally to them are placed 2 further smaller eye-spots and between them 2 oval spots with a silver line in the middle. The ♀ is above brown, at the base purple with a white band traversing the middle from the costal margin of the forewing to the hindmargin of the hindwing. The under surface is grey-brown with the same white band. The eye-spots as in the ♂. From the Amazons.

E. metagera *Btlr.* Above brown, in the middle whitish, with 2 indistinct brown median bands and *metagera*, 3 dark brown marginal lines. Hindwing with a dark spot at the apex and an eye-shaped spot at the anal angle. Wings beneath lighter, towards the apex rose-reddish, bands as above, but more distinct. Hindwing with 6 yellow-bordered eye-spots, of which the 2 middle ones are oval and have oval silvery dots, the others round, black and with small silvery pupils. From the Upper Amazon.

E. hiemalis *Btlr.* Above white, costa and margin of the forewing brown, both wings with 3 brown mar- *hiemalis*, ginal lines, hindwing with 2 brown spots at the apex and one at the anal angle. Beneath likewise white with 2 brown median lines, which are abbreviated on the forewing, and of which the distal one is angled before the inner margin of the hindwing. Costal margin and apex of the forewing brown, 3 marginal lines as above, hindwing with 6 ocelli, some round, others oval, just as in *metagera* except that they are margined with red-yellow. From the Amazon and its tributary the Rio Negro.

E. julia *Stgr. i. l.* (48 g). Above dark olive-brown with 2 indistinct marginal lines on the hindwing, *julia*. Beneath likewise olive-brown with a straight white median stripe, which extends from $\frac{1}{2}$ the costal margin of the forewing to the anal angle of the hindwing, and with 3 brown marginal lines on the somewhat lighter distal margin, the inner one undulate. Forewing before the apex with a small black eye-spot with red-yellow ring and white pupil, hindwing with 5 ocelli, the 1st, 2nd and 5th coloured like the one on the forewing, but (except the first) larger. The others are brown with 2 short white streaks in the middle. In the ♀ the ground-colour is somewhat lighter brown, otherwise it is like the ♂. From the Songo in Bolivia and Cuzco in Peru at elevations of 2—3000 m. — **torva** *form. nov.* (48 g) is a form of *julia*, differing in having the median band on *torva*, the under surface not white, but strongly dusted with grey-brown and before the anal angle of the hindwing bent basewards in an acute angle. Found by FASSEL in October at the Quindiu-Pass in Colombia at 2500 m.

Cluena Group.

E. cluena *Drury* (= *clueria* F.) (48 g). Above violet-grey, distally darker with 3 dark brown marginal *cluena*, lines, hindwing with a continuous row of 5 dark brown spots, of which the posterior 4 have lilac spots in the middle. Beneath entirely lilac with very fine brown median and marginal lines. In the marginal area a nebulous brown band, on which on the forewing are placed 2 or 3, on the hindwing 5 small ocelli, the 1st on the forewing, the 1st, 2nd and 3rd on the hindwing black, the others brown, all with ochre-yellow ring and white pupil. From Brazil (Rio de Janeiro, Espírito Santo).

Byses Group.

E. byses *Godt.* (49 d). Above in the ♂ brown with slight bluish violet reflection, otherwise without mark- *byses*, ings. Beneath lilac, finely striated with brown all over. At the distal margin this striation is gradually condensed into an entirely brown colouring. Close to the distal margin are placed on the hindwing in cellules 2 and 5 two small black eye-spots with white pupil and yellow ring; between and before these 3 white dots. Before the apex of the forewing 3—4 white dots. The ♀ is above unicolorous brown without blue reflection, the

eye-spots on the underside of the hindwing, however, are much larger than in the ♂, and there is further a quite small eye-spot before the apex of the forewing beneath. The size of the eye-spots varies greatly. From Brazil.

Lea Group.

- lea*. **E. lea** Cr. (48 f). Above glossy blue, apex, costal and distal margins of the forewing and the greater part of the veins black. Beneath brownish grey, the posterior half of the hindwing in the ♂ glossy blue, in the ♀ more blue-grey. Both wings with 2 nearly straight, parallel dark brown median stripes, of which the proximal on the forewing does not reach the costal and inner margins, and with 3 marginal lines. Forewing with 2 small eye-spots before the apex, hindwing with 6 black eye-spots, each with white pupil and surrounded by an ochre-yellow ring and outside it a brown one, only the 2nd and 5th large, the others very small. From Surinam. —
- junia*. **junia** Cr. is a form of *lea* with the upper surface entirely sky-blue and only bordered by a narrow black marginal line. On the under surface of the forewing only one eye-spot is present. The ♀ has the margins of both wings brown. From Surinam and Brazil (Pará and Bahia). —
- philippa*. **philippa** Btlr. is a form belonging here, in which the upper surface is entirely brown and only the hindwing is blue-grey in the ♂ towards the apex and in the ♀ towards the base. There are also 2 indistinct brown marginal lines, which are undulate towards the apex of the forewing and on the hindwing. The under surface is exactly as in *junia*. The antennae are above brown, beneath rust-coloured, towards the tip ringed with black, the tip itself white. From Ega.

Cephus Group.

- cephus*. **E. cephus** F. (♂ = *lysidice* Cr., ♀ = *doris* Cr.) (49 b). The ♂ is above glossy sky-blue. Forewing with the costal and distal margins blackish grey; a stripe of the same colour runs from the base over the median and is divided on the branches of this vein; all the veins are blackish grey at the distal margin. On the hindwing all the margins are the same, only the inner margin somewhat lighter. The under surface is likewise sky-blue with brown transverse stripes and marginal lines, one eye-spot on the forewing and 4 on the hindwing. The ♀ is above unicolorous grey-brown, with bluish white terminal line at the margin of the hindwing. The under surface is quite similar to the ♂, except that the eye-spots are larger. This beautiful species is widely distributed in South America; it occurs in almost the whole of the Amazon country; further in Surinam, Colombia and South Brazil (Rio de Janeiro). —
- angelica*. **angelica** Btlr. is a form of *cephus* which only differs in its larger size (48 mm.), in having an undulate, inner marginal line on the under surface and in the transverse stripes on the forewing only reaching to the middle. From Rio de Janeiro.
- parthenie*. **E. parthenie** spec. nov. (48 f). Above bluish grey-brown with 2 dark brown marginal lines, between which on the hindwing is placed a whitish line, otherwise without markings. Beneath light bluish grey with 2 narrow median stripes, a fine submarginal line and 2 fine marginal lines. The outer of the median stripes is somewhat proximally curved on the forewing, hence the marginal area is broader than usual. Forewing with 1 eye-spot, hindwing with 6, of which the 2 middle ones are indistinct, the 1st and last small, the other 2 somewhat larger. (38 mm.). From Minas Geraes. Of this species I received a female from the THIEME collection, determined as *angelica* ♀; but as it is much smaller than *angelica* ♂ and the colouring and pattern are quite different from *cephus*, I regard it as a separate species.
- glaucina*. **E. glaucina** Bates (49 b). Above pale blue-grey, not glossy, forewing grey-brown at the apex and the costal and distal margins, veins on both wings and the 3 marginal lines of the hindwing likewise grey-brown. Beneath pale blue with 4 brown lines before and behind the middle and 2 marginal lines. Forewing with one, hindwing with 4 ocelli as in *cephus*. The ♀ is unicolorous brown above. Rather widely distributed in Mexico and Guatemala from the lowlands up to 1500 m. —
- glauca*. **glauca** Stgr. i. l. (49 b) is a more restrictive form of *glaucina*, in which the forewing is almost entirely dusted with grey-brown and the blue colouring is only present near the inner margin. An elongate, more thinly scaled spot is placed at the middle of the inner margin. The hindwing is somewhat brighter blue than in *glaucina*, with black costal margin and 3 black marginal lines. The under surface is likewise similar to *glaucina*, but has 5 eye-spots on the hindwing in cellules 2—6, the two in cellules 2 and 5 larger, black with 1 bluish white and 1 brown ring, without pupils, the others small, indistinct, consisting of a brown ring, which is filled up with the blue ground-colour and has a brown central dot. The eye-spot in cellule 1 c of the hindwing is thus absent here. From Bolivia.
- brixius*. **E. brixius** Godt. Above bluish grey with 6 dark brown transverse stripes and 2 marginal lines. Beneath the ground-colour is lighter, the stripes as above; on the 4th stripe of the hindwing are placed 5 eye-spots, of which the 1st, 2nd and last have white iris, but the other two are without iris. All these eye-spots are black with double silvery pupils. 38 mm. From Brazil. —
- brixiola*. **brixiola** Btlr. is a somewhat smaller form of *brixius*, which according to BUTLER's description has one less transverse stripe on the wings. The ♂ is above light grey, the ♀ light brown, on the 4th stripe the hindwing has 2 indistinct black eye-spots with white pupils. The under surface is bluish white, with the stripes as above. Before the apex of the forewing in the ♀ a black, yellow-ringed eye-spot with silvery double pupil and 2 indistinct eye-spots below it (in the ♂ these are all obsolescent). On the hindwing five similar ocelli, always distinct, of which the 2nd and 5th are larger, only the 3rd and 4th entirely silvery and with yellow rings. 35 mm. From Pará.

E. aegrota *Btlr.* (49 b). Above bright blue; forewing with black margin and two black median stripes; *aegrota*, hindwing with narrow margin and oval spot at the anal angle. Fringes white. The under surface is similar to that of *cephus* and *glaucina*, but the submarginal line is more dentate, the eye-spots in cellules 2 and 5 of the hindwing larger, the one in cellule 1 c absent, on the other hand in cellules 3 and 4 are placed between the eye-spots two brown rings with blue centres and on the forewing in cellules 3 and 4 likewise two similar brown rings with blue centres and brown central dots. From Pará and from the upper Madre de Dios in Peru.

E. aetherialis *Btlr.* above approaches *aegrota*, but is very different beneath, and the distal margin *aetherialis*, of the forewing is not rounded, but nearly straight. The ground-colour of the upper surface is of the same blue as in *aegrota*, the inner of the median lines is indistinct and the black anal spot of the hindwing is smaller. Beneath the wings are silvery blue with 2 narrow rust-red median lines, which are angled before the inner margin of the forewing, a submarginal line of the same colour and 2 dark brown marginal lines. Forewing with 3 small eye-spots in cellules 4—6, the anterior one with yellow iris, the other 2 indistinct; hindwing with 5 eye-spots, of which the first 2 and the 5th are black, while all have yellow rings and white pupils, the pupils of the 2nd and 5th being double. 40 mm. From Sarayacu, Ecuador.

E. coelestis *Btlr.* (48 g). Above blue, apex and costal and distal margins of the forewing broadly *coelestis*, dark brown with two abbreviated median stripes, hindwing with 2 marginal lines and a submarginal likewise dark brown. Beneath blue, 2 median stripes, a somewhat abbreviated band on the forewing in the marginal area, a submarginal line and two marginal lines brown. On the forewing 2 eye-spots before the apex, black with blue and outer brown ring, the lower one only small; hindwing with 5 similarly coloured eye-spots in cellules 2—6, the 2nd and 5th large, the others all small. The ♀ is somewhat larger (47 mm), and has the costal margin of the hindwing above rather broadly dark brown and at the anal angle a dot of the same colour. From the Amazons (Ega) and the Mapiri. — **mare** *Btlr.* is a smaller form, in which the median stripes on the upper surface are almost entirely obsolete and on the under surface the eye-spots are smaller and in part indistinct, the bands also narrower and faint. From Pará.

E. caerulea *Btlr.* (49 b), similar to *coelestis*, above glossy blue. Apex and distal margin of the forewing *caerulea*, broadly dark brown, the costal margin narrowly dark brown along the costal vein. On the hindwing the apex and 2 fine marginal lines are dark brown. The under surface is light glossy blue with 5 nearly straight brown transverse lines and fine marginal lines, only the 2 distal lines on the hindwing undulate. At the distal side of the 3rd transverse line are placed on the forewing an eye-spot before the apex, on the hindwing 3 eye-spots, namely 2 at the apex, one at the anal angle. These eye-spots are black with blue ring and outer brown ring. The ♀ is somewhat larger and has above on the forewing 2 brown median stripes and on the hindwing a brown anal spot. From Maranhao (Brazil) and the Mapiri (Bolivia).

E. ziza *Btlr.* is similar to *coelestis*, but somewhat smaller, and the brown ground-colour has a violet *ziza*, tone. The 2 median bands of the forewing are placed nearer together, are parallel and reach the inner margin; the marginal band is somewhat narrower. The hindwing in addition to the 2 marginal lines has also a median line. Beneath light blue with 2 brown median bands, 2 marginal lines and an eye-spot on the forewing, as well as 5 ocelli on the hindwing, all black with white rings, but the 3rd and 4th indistinct. From Pebas in Peru.

E. urania *Btlr.* is likewise allied to *coelestis*, and of the same size. Above glossy greenish blue with *urania*, very broad brown distal margin, the costa and a streak behind the cell likewise brown. Hindwing with 2 brown marginal lines. Beneath with 4 transverse lines across the middle and before the margin; further with 2 marginal lines, all brown. Apex of the forewing and anal angle of the hindwing likewise brownish. Forewing with an indistinct black eye-spot before the apex. On the hindwing only the 2 larger eye-spots are distinct. From Cametá near Pará.

E. coelica *Hew.* Above sky-blue, apex and distal margin broadly black; on the hindwing a band *coelica*, at the apex, two submarginal lines and the fringes black. Beneath likewise sky-blue, both wings with 2 stripes before the middle, 2 submarginal lines and the fringes dark brown. Before the apex of the forewing a black eye-spot bordered with brown. At the apex of the hindwing 2 similar eye-spots (the first smaller), and at the anal angle a third eye-spot. Between them 2 brown flexuose rings. From Ecuador. HEWITSON remarks that this species surpasses in beauty all the allied blue species; but the following *divina* is no less beautiful.

E. divina *Stgr. i. l.* (49 c) ♂. Quite similar above to the preceding species; bright sky-blue with *divina*, the apex and distal margin of the forewing broadly black, apex and 2 marginal lines of hindwing black. But the under surface differs in the larger number of the ocelli and of the median stripes. On the forewing before the apex two black eye-spots with light blue and outer brown ring and one or 2 brown spots posteriorly to them. On the hindwing 5 large, similarly coloured eye-spots in a straight row. The outer brown rings touch on the veins and on the proximal side of the eye-spots a brown stripe runs from vein 2 to the costal margin,

so that 3 median bands are present. Occasionally the anterior ocelli of the hindwing have blue central dots. From Bolivia.

lobelia. **E. lobelia** *Btlr.* ♂: above sky-blue, apex and distal margin of the forewing broadly black, the veins before the margin the same, also a streak on the discocellular and an almost triangular ring behind the cell. The hindwing has the apex and 2 marginal lines black. The inner angle is more strongly produced than in the allied species. Beneath blue, with a basal streak, 2 median lines, a discal line and 3 marginal lines, all black. Forewing with one, hindwing with 2 blind black eye-spots of unequal size at the apex. 45 mm. From Ecuador.

helios. **E. helios** *Stgr. i. l.* (49 c) ♂. Above similar to *mare Btlr.*, dark blue, at the costal margin somewhat lighter, forewing with a straight black stripe across the discocellular, reaching to the first median vein. Distal margin black for a breadth of 2 mm., increasing at apex to 5 mm. Hindwing black at the apex, with 3 black marginal lines. Under surface light blue with red-brown, black-edged transverse stripes and brown marginal lines. On the forewing in cellules 3 and 4 two round ochre-yellow spots and above them in cellule 5 a brown ring, which is filled up with ochre-yellow and has a brown dot in the middle. Hindwing with 5 ocelli, the 1st, 2nd and 5th black with white pupil, that of the 5th eye-spot double, all with ochre-yellow iris and outer brown ring; the 3rd and 4th consist only of a brown ring, filled up with ochre-yellow. From the Mapiri in Bolivia.

periboea. **E. periboea** *Godm. & Salv.* (49 c). The ground-colour of the upper surface is blue inclining to grey. Apex, costal and distal margins of the forewing are dark brown. The hindwing has 3 dark brown marginal lines. Beneath the wings are brown with 2 dark brown median lines, a dentate submarginal line and 2 marginal lines. In the marginal area of the hindwing are placed 5 eye-spots, on the forewing the number varies from 1 to 4, or they are here entirely absent. They are small, black, with white pupils and brownish yellow rings. An easily recognizable species. From Colombia (Manaure in the Sierra Nevada from Santa Marta [SIMONS]) and in Paima near Muzo, 1000 m., in October [FASSL].

Pilata Group.

The ♂♂ of this group are distinguished by an oval spot of raised or hair-like scales, placed at the middle of the inner margin on the upperside of the forewing.

cyanites. **E. cyanites** *Btlr.* (= *stigmatica Godm.*) (49 c). The ♂ is sky-blue above, almost like *coelestis*, with black stripes and bands, but with the inner line on the forewing absent, inner margin of forewing with a whitish, grey-scaled spot. Beneath the bands are more reddish and the eye-spots smaller than in *coelestis*, otherwise like the latter. Moreover *cyanites* is larger. The ♀, which I received from coll. THIEME as *stigmatica* ♀, is very different from the ♂. It is grey-brown above, with a very slight bluish reflection in the basal half both wings, with 2 marginal lines on the forewing, 3 on the hindwing, of which only the outer one is distinct. Fringes grey. Under surface bluish grey, with 2 brown lines through the middle, the distal one somewhat undulate, a strongly dentate submarginal line and 2 marginal lines, the latter on the hindwing undulate, with one distinct and several (3 or 4) indistinct ocelli on the forewing and 6 eye-spots on the hindwing in cellules 1 b to 6, all black with white pupil, ochre-yellow ring and brownish bordering, the outer 2 smaller, the middle 2 rather indistinct. BUTLER gives Brazil as locality, GODMAN received *stigmatica* from Entre Rios in Argentina, HAENSCH took both sexes in Minas Geraes.

pilata. **E. pilata** *Btlr.* (49 c). Above sky-blue. Forewing with dark brown apex, costal and distal margins the same and with grey-brown hair-pencil over the inner margin. Under surface bright, glossy blue with 2 straight brown median lines, 2 marginal lines and a somewhat stronger submarginal line. Forewing with an eye-spot before the apex, with 2 small black spots below it and a lighter one above it. Hindwing with 4 eye-spots, 2 at the apex and 2 at the anal angle, the first and last small. These eye-spots consist of a thick orange-yellow ring with obliquely placed black pupil and an outer brown ring. Between the eye-spots are placed 2 thin brown rings, filled up with the blue ground-colour. From Ega (Teffé) and Tabatinga on the Amazon.

tenera. **E. tenera** *Stgr. i. l.* (49 c). Above dark blue, forewing with broad, washed-out, black distal margin and black veins. At the middle of the inner margin a short dark brown hair-tuft. Hindwing with undulate dark marginal lines. Inner margin grey. Beneath light greenish blue with 2 straight brown median lines, a curved band in the marginal area and undulate marginal lines. Forewing with a small blind eye-spot before the apex and below it a short brown nebulous band. Hindwing with 5 eye-spots of uniform size; these are black with ochre-yellow and outer brown rings and white pupils, the 3rd and 5th bi-pupilled. From the Rio Juntas in Bolivia.

penicillata. **E. penicillata** *Godm.* ♂: above greenish blue with narrow brown margins and with a thick pencil of brown hairs over the inner margin of the forewing. Beneath greenish brown with 2 fairly straight median lines, an undulate submarginal and 2 marginal lines, all dark brown. Forewing with 3 ocelli, the first somewhat

more distinct; hindwing with 5 eye-spots, the 2nd and last larger than the rest. The eye-spots are black with white pupils and yellow and outer brown rings. The ♀ is above unicolorous brown, beneath quite like the ♂, except that the ground-colour is light brown, towards the distal margin grey. (38 mm). From Tapajos (Amazons).

E. scopulata (49 d). ♂: similar to the preceding species, with a similar hair-tuft on the forewing, but *scopulata*, with the upper surface not blue, but brown with dark brown marginal lines and somewhat lighter fringes. Under surface grey, the stripes through the middle of the wings broader and red-brown, on the forewing 2 or 3 eye-spots present, on the hindwing 5, of which, as in *penicillata*, the first on the forewing and the 2nd and 5th on the hindwing are larger and more distinct than the rest. The latter is bi-pupilled. From the Mapiri in Bolivia and the Upper Amazon.

Arnaea Group.

E. arnaea F. (= *ebusa* Cr., *aranaea* F.) (49 d). Above brown, the larger posterior half of the hindwing *arnaea*, with bright blue reflection. In the ♀ this reflection extends over the whole hindwing and also occupies the inner margin of the forewing. The ♀ is further distinguished by having on the hindwing before the 2 marginal lines a dentate, dark brown submarginal line, which is wanting in the ♂. In addition the 2 dark brown median lines on the forewing are somewhat broader in the ♀. The light brown under surface has likewise a blue reflection in the ♂, but this is much weaker than above, occasionally, however, extending, beyond the 2nd median stripe, nearly to the costal margin of the forewing. In the ♀ the reflection on the under surface is less visible. Widely distributed and rather common. Nicaragua, Costa Rica, Panama, Guiana, Colombia, Amazons. — GODMAN and SALVIN (in Biol. Centr. Americana I, p. 89) question the correctness of employing the name *arnaea* for this species and consider that of *ebusa* Cr. more correct, as FABRICIUS himself in his Species Insectorum Vol. II, p. 75 has cited *Euptychia lea* Cr. (with a !, however). But as *lea* has both wings blue above, while FABRICIUS only speaks of blue hindwing and describes the forewing as brown, I am of the opinion that KIRBY and BUTLER are right in employing the name *arnaea* for *ebusa* Cr.

E. sericella Bat. ♀ similar to the preceding, but both wings above blue. Apex and distal margin of *sericella*, the forewing broadly dark brown, the costal margin narrow, with 2 fine brown median lines. The hindwing has brown fringes and 2 brown marginal lines with a reddish line between them. The under surface is according to BATES tawny brown with 2 dark brown median lines, the outer somewhat thicker and distally bordered by a straight, light lilac stripe; at the distal margin 2 dark brown median lines. Before 3 or 4 eye-spots on the forewing and 5 on the hindwing. Of the latter the 2nd and last are black with white pupil and yellow iris, the rest white with yellow iris. But the figure in the Biologia Centrali-americana does not agree with this description of BATES' in two points. The ground-colour in the figure is not tawny brown but dark brown, so that the transverse lines can scarcely be seen, and the difference in the colouring of the eye-spots mentioned by BATES is not discernible. As the species is represented in but few collections and is not known to me in nature, I cannot decide whether figure or description is correct. Very rare in Mexico (Orizaba) and in Guatemala (Vera Paz and Choctum).

E. chloris Cr. (= *chlorimene* Hbn., *tolumnia* ♀ Godt.) (49 e). The wings of this species are very thinly *chloris*, scaled, hence the markings of the under surface show through above. The upper surface is brown; in the ♂ the inner angle and the inner margin of the hindwing have a blue reflection. In the ♀ this reflection, which is here more violet, is extended over the whole hindwing and the greater part of the forewing. The under surface is in both sexes glossy violet-blue with broad, reddish brown median stripes, one eye-spot on the forewing and 5 on the hindwing, of which the 4th is of a flattened form and is divided longitudinally by a silver stripe, while the 3rd is little prominent and only recognizable by its round silvery central spot. The species is common in Surinam, on the Amazon and in Bahia. — **agatha** Btlr. (49 e) is a form of *chloris* in which the distal margin *agatha*, of the forewing is less excised and the hindwing more ample; the brown ground-colour is darker and the blue colouring on the hindwing more extended. On the under surface the outer median band on the hindwing forms an obtuse angle in the middle and an acute angle at the inner margin. The ocelli are larger. The 2nd eye-spot is placed so near to the distal margin that it touches the submarginal line. The 3rd and 4th eye-spots consist of elongate orange-yellow rings with silvery centres. The ♀ is more thinly scaled, of more violet colour, with red-brown margins; the ocelli of the under surface show through above. Beneath the median bands of the hindwing are placed nearer together. From Pará. — A considerably larger form of 45 mm. expanse I name **agathina** *form. nov.* It has much broader wings, is more thickly and densely scaled and hence not trans- *agathina*, parent. Above dark brown, the greater part of the hindwing dark steel-blue, only the costal margin dark brown for a breadth of about 10 mm. The under surface has on both wings a bright blue reflection, especially in the posterior half of the hindwing. The median bands are dark brown and on the hindwing straight, only on the forewing the 2nd band is somewhat distally curved before the inner margin. The two elongated eye-spots of *agatha* are here not bordered with orange-yellow but with brown. From Macas in Ecuador.

marica. **E. marica** *Stgr. i. l.* (49 e). The wings are thinly scaled, above brown with dark violet-blue reflection, which gradually shades into the broad brown distal margin. The bands and eye-spots of the under surface show through above. Beneath light violet with bluish gloss. The forewing with 3, the hindwing with 2 broad brown transverse bands, the distal forming an angle on the median of the hindwing and an acute angle distad before the inner margin. Forewing with one, hindwing with 3 ocelli, all black with yellow and brown rings and white pupils, the posterior eye-spot bi-pupilled. Between the eye-spots of the hindwing the yellow-brown, oval spots with silvery pupils as in the allied species. *marica* is easy to distinguish from the latter by having the two larger ocelli in cellules 2 and 5 of equal size. From Pebas on the Amazon in Peru.

herse. **E. herse** *Cr.* (= *herseis* *Godt.*) (49 e). Above dull violet with blue reflection. Forewing with brown costal and distal margins, the latter twice as broad as the former, with 2 straight median stripes, 3 marginal lines and a round brown spot before the apex. On the hindwing the first median stripe is straight, the 2nd forms on the median a sharp, distally directed tooth. Before the anal angle a large black eye-spot with yellow ring and at the apex 2 smaller, obscure eye-spots. Beneath the ground-colour is light violet-grey, the transverse stripes yellow-brown. Forewing with one eye-spot, hindwing with 3, the first very small, the last large, all black with red-yellow and brown rings, all (also the one on the forewing) with double white pupils. Between the eye-spots in cellules 3 and 4 two red-yellow spots with silvery centres. From Surinam, Pará, Merida (Venezuela) and Villavicencia (East Colombia [FASSEL]).

callichloris. **E. callichloris** *Btlr.* Similar to *herse*. Above brown. The wings at the base transparent, violet. The third band on the forewing nearer to the margin, the first on the hindwing indistinct, the others strongly angled, the anal eye-spot large and black, with yellow ring, the others indistinct. The under surface is according to BUTLER's figure lilac, according to his description whitish, the bands of the forewing as above. On the hindwing the basal area is filled up with brown to the first transverse band, the 2nd band forms an acute angle distad. The yellow rings round the eye-spots are very broad, interrupting the brown bordering, and forming a continuous yellow band on which are placed in cellules 2 and 5 round black spots with silvery double pupil and in cellules 3 and 4 silvery streaks. The eye-spot in cellule 2 is larger, that in cellule 5 smaller. The still smaller eye-spot in cellule 6, which is likewise black and has a double silver pupil, is isolated and placed in a yellow and brown ring. From Ega (on the Amazon).

Tolumnia Group.

On the upperside of the forewing in the ♂♂ is placed at the hindmargin of the cell a narrow stripe of scent-scales adjoining the stalk of the median and consisting of hair-like scales.

tolumnia. **E. tolumnia** *Cr.* (49 f). Above dark brown, the posterior half of the hindwing with bright blue gloss. The stripe of scent-scales of the ♂♂ along the median of the forewing is distinct. On the under surface the ground-colour is more yellowish between the transverse stripes and only the distal half of the hindwing is light bluish violet. The eye-spots have silvery pupils, those of the last larger eye-spot are double and produced lengthwise. From Surinam, the Lower Amazon and Bahia.

catharina. **E. catharina** *Stgr.* Forewing brown, in the ♂♂ with a narrow stripe of hair-shaped black-brown scales along the median, otherwise without markings. Hindwing almost entirely blue, only the costal margin broadly, the distal and inner margins narrowly brown. On the under surface the basal half of the forewing and the anterior part of the hindwing are brown-grey, the distal margin of both wings and the inner margin of the hindwing light blue. Forewing with 3 narrow brown transverse stripes, hindwing with 2 which diverge posteriorly. Before the inner margin of the hindwing the outer stripe forms an angle. Forewing with 1, hindwing with 2 small eye-spots at the apex and a large one in cellule 2, between them the 2 yellow ellipses with silver dots as in *tolumnia*. 36 mm. From Jurimaguas in the Upper Amazon district.

hewitsonii. **E. hewitsonii** *Btlr.* (= *polla* *Möschl.*) (49 e). A small but beautiful species. Brown, the scent-scale stripe of the ♂ somewhat darker. The distal margin with blue reflection, the inner margin bright glossy blue. Hindwing at the base whitish, distally with blue reflection. Both wings with white fringes. Vein 1a on the ♂ hindwing somewhat thickened in the middle. Forewing beneath lilac, with 3 red-brown transverse stripes, 2 straight marginal lines and an eye-spot before the apex. Hindwing at the base lilac, distally blue with 2 transverse stripes, 2 eye-spots at the apex and a very large anal ocellus; between the eye-spots 2 brownish yellow ellipses with silvery blue centres. From the Lower Amazon (Pará). BUTLER mentions a form from the Upper Amazon (Ega, now Teffé) without naming it; it differs in having the ground-colour above and beneath more greenish. *polla* *Möschl.*, from Surinam, I regard as likewise a *hewitsonii*, as the figure and description almost entirely agree with this. The only difference in the figure consists in the absence of the elliptical spots on the hindwing. But in the text MÖSCHLER mentions these as present, so that this may be only an error in the figure. The 2nd difference that I find is in the marginal lines on the underside of the forewing. These are straight in *hewitsonii*, MÖSCHLER describes the inner of these lines as finely dentate. According to the figure which he gives of his *polla*, however, both are straight. Hence I can only regard *polla* as a synonym of *hewitsonii*.

Agaya Group.

E. agaya *Btlr.* (= *iris* *Fldr.*) (49 g). Above brown with dark brown reflection, which does not quite *agaya*, reach the margins of the wings. In the middle of the hindwing is placed at the end of the cell a tuft of brown hairs, in the vicinity of which the ground-colour is darker. Under surface violet-grey, forewing with 3 broad, straight, brown transverse stripes, 2 marginal lines and a black eye-spot, ringed with brownish yellow, before the apex. Hindwing with the same bands, 3 dentate lines before the distal margin and 3 eye-spots in cellules 2, 3 and 6, all bi-pupilled. In the ♀ the hair-tuft and the dark spot on the upperside of the hindwing are absent. From the Amazon (Tapajos), Colombia (Bogotá). Taken by FASSL in the Llanos of Medina in East Colombia (400 m.) in June.

Doxes Group.

E. doxes *Godt.* (= *erycina* *Btlr.*) (49 d). Above grey-brown with slight bluish grey sheen and with 2 *doxes*, dark brown marginal and a similar terminal line. On the hindwing are placed 2—4 round dark brown spots in cellules 1 c, 2, 3 and 5, the two last are often absent. The under surface is somewhat lighter and has 2 dark brown median lines, of which the outer one is more or less strongly angled on the hindwing. Forewing without eye-spots, hindwing with 5 or 6 elongate oval ocelli, red-yellow with black pupils, the inner half of which is densely sprinkled with white, silvery scales: the first and the last eye-spot are smaller than the rest. The number of the eye-spots varies, Prof. SEITZ has taken both examples with 6 and those with 5 ocelli flying at one place. From Brazil (Esperito Santo).

E. latia *Btlr.* Above brown, hindwing with a rather large ochre-yellow patch before the margin, 4 black *latia*, spots and undulate ochre-yellow submarginal line. Beneath brown, the distal part of the hindwing whitish, the margin itself brown, the median lines as in *doxes*, but further separated, hindwing with 6 large, oval eye-spots, ringed with red-yellow, the first 2 and the last 2 with large black pupils, dusted with silver at the proximal side, the other 2 with entirely silvery, oval pupils. From Bahia.

E. furina *Hew.* (49 d). Above brown, the hindwing with large white median area, at the margin of which *furina*, are placed some black spots. Forewing beneath brownish grey, with 2 reddish brown median bands, an indistinct grey-brown band in the marginal area with a silver spot in the middle and 3 brown marginal lines. Hindwing white with 2 reddish brown median bands. In the marginal area 6 red-yellow, elongated eye-spots form a broad band, enclosing in each cellule a large spot, which is distally black, proximally dusted with silver and conically pointed. At the margin 3 terminal lines. From the Amazons.

E. junonia *Btlr.* The forewing rather elongated, above brown, without markings, hindwing with three *junonia*, dark brown marginal lines and two light lines between them. Beneath brownish grey, with 2 brown median bands, the inner one scarcely reaching the middle of the inner margin of the hindwing, the outer terminating at the 6th eye-spot. These eye-spots are as in *furina*, but the first two smaller. From Tapajos (Amazons).

E. gemmula *Btlr.* Above brown, the hindwing at the anal angle lighter, with 1 or 2 black spots and 2 *gemmula*, black-brown or rust-brown marginal lines. Beneath lighter with 2 narrow, rust-coloured, widely separated median stripes and 2 angular marginal lines, brown on the forewing, rust-coloured on the hindwing; the distal margin itself narrowly black. Hindwing in the ♂ with 5, in the ♀ with 6 eye-spots, which, however, are more round than oval and are all broadly margined with yellow. The pupil of the 2nd and of the 5th eye-spot is distally black, proximally greenish silvery, the others have the pupils entirely greenish silvery. Rio de Janeiro.

Clorimene Group.

E. cosmophila *Hbn.* (♀ = *argenteus* *Swains.*) (49 f). Above grey-brown. The distal margin darker, *cosmophila*, before the margin of the hindwing a washed-out brownish ochre-yellow patch, in which are placed 1 or 2 round black spots with or without white central dot. 3 dark brown marginal lines. Beneath much lighter, with 2 widely separated, fine brown median lines and 3 dark brown marginal lines. Forewing in the marginal area with a row of brown spots, which are sprinkled with fine gold dots and enclosed both proximally and distally by an undulate brown line. On the hindwing is placed in the marginal area an ochre-yellow band, anteriorly narrow, posteriorly broad, on which are scattered 6—8 shining golden spots, and in cellule 2 a black spot with golden double pupill. Brazil (Parana, Bahia).

E. clementia *Btlr.* Above light olive-brown with indistinct dark median line and somewhat darker *clementia*, margin. Hindwing with 4 brown discal spots and 2 dentate marginal lines on a lighter ground. Beneath lighter with 2 dark brown median lines, diverging anteriorly on both wings, and 3 dark brown marginal lines. In the marginal area of the forewing are placed on a brown band a row of indistinct, silver-dusted eye-shaped spots. On the hindwing the disc is snow-white and traversed by a broad, ochreous, brown-margined band, which contains 3 black eye-spots with silver pupils (2 at the apex and one at the anal angle). Between and behind the eye-spots some elongate silver spots. From Chanchamayo in Peru.

- telesphora*. **E. telesphora** *Btlr.* (= *telesiphora Kirby*) (49 f). Above brown with 3 darker marginal lines, hindwing in the middle somewhat lighter, at the anal angle a dark brown spot. Beneath grey-brown with a row of black, silver-centred dots, enclosed in groups of 2 or 3 by brown rings, all again enclosed by an outer brown line. Hindwing light yellowish, at the margin reddish yellow with 3 black eye-spots with silver pupils as in the preceding species, and with several silver dots between and behind them, all margined with black. From the Marcapata (Peru).
- clorimene*. **E. clorimene** *Stoll.* Above brown with the distal margin lighter; hindwing with a narrow and a somewhat broader, dentate, pale yellow marginal stripe and a small eye-shaped spot at the anal angle. Beneath lighter, the distal margin brownish yellow, with narrow brown transverse lines and a broader brown stripe, which is intersected by a silver line. On the middle of the hindwing a broad light brown transverse band, through which runs a yellow-brown stripe. The marginal area is brownish yellow with 4 round silver spots, placed in black rings. Between and behind these rings are placed 3 silver streaks, which reach the distal margin. The distal margin itself is bordered by 3 black and 2 light yellow lines. From Surinam. Rare.
- pagyris*. **E. pagyris** *Godt.* (49 f). Above brown, forewing without markings, hindwing towards the anal angle whitish with 3 black dots, of which the middle is the largest. The forewing beneath brown with 2 rust-coloured transverse stripes and before the distal margin a row of silvery dots. The hindwing beneath in the basal half grey with the same 2 rust-coloured transverse stripes as the forewing, in the distal half yellowish with 7 silver spots, of which 5 are nearly round and placed parallel to the distal margin, the other two, and especially the one next to the inner margin, elongated and reaching the second rust-coloured stripe. Between the 4th and 5th of these round spots there is a large, oval, black spot, transversely placed and marked with 2 thick silver dots. On the grey distal margin are placed 2 blackish undulate lines. From Brazil.
- hygina*. **E. hygina** *Btlr.* (49 f). Pale olive-brown. Hindwing with a large red-yellow discal spot, surrounded by 5 blackish spots, of which the 3 smaller, anterior ones form a triangle. Beneath whitish brown, the transverse lines and silver spots similar to those of the preceding species, but the 2nd transverse line on the hindwing very irregular and the marginal area beyond it almost entirely filled up by the bright red-yellow bordering of the silver spots. From Brazil (Joinville).
- salvini*. **E. salvini** *Btlr.* (49 f). Grey-brown, basal half of the forewing lighter. The dark transverse stripes of the under surface show through distinctly above. The hindwing in the middle whitish with 2 round black spots at the apex and a larger one in cellule 2, between them two smaller ones nearer to the distal margin. Beneath white, forewing with 6 brown transverse stripes, the first oblique, the 4th and 6th connected anteriorly and posteriorly, so that they enclose the 5th stripe, on which is placed a row of silver dots. The hindwing has in the basal area 3 straight brown stripes and in the ochre-yellow marginal area, which is posteriorly bordered with brown, an angled row of silver spots, some of them in black rings. From Panama and Peru.
- itonis*. **E. itonis** *Hew.* (49 g). On the upper surface the space between the 3 black marginal lines of the hindwing is reddish brown, and towards the anal angle white. The large white area of the hindwing is divided on the under surface by 2 brown transverse lines, which are here present also on the forewing. For the rest the ground-colour beneath is grey-brown. In the marginal area of the forewing are further 6 parallel brown lines, posteriorly somewhat convergent; among them is a somewhat broader stripe, enclosing a row of silver dots. In the ochre-yellow marginal area of the hindwing, which is distally bordered by an undulate, proximally by a dentate, brown line, is placed at the anal angle a black eye-spot measuring over 3 mm., with thick silvery pupil, behind it 3 small silver spots and before it 6 somewhat larger ones. From the Amazons (Pará). — **quadrina** *Btlr.* is a form of *itonis* in which the white area of the hindwing has acquired an almost quadrate shape. The lines on the under surface of the forewing are more widely separated and not curved posteriorly. From Maranhão.
- libitina*. **E. libitina** *Btlr.* Above brown with a triangular black median spot and 2 marginal lines, hindwing at the distal margin lighter with 3 black marginal lines. Beneath much lighter. Forewing with 2 brown median and 3 submarginal lines, between them a white band with silver-pupilled spots. Hindwing with 2 ochre-brown median lines, the distal part orange with 8 silver spots, a short white, black-edged band and a similar dot before the margin, a black spot at the anal angle, divided by a white line, and with a small, black-bordered silver spot above it. 43 mm. From Brazil. Rare, only in coll. DRUCE.

Phocion Group.

- phocion*. **E. phocion** *F.* (= *areolatus Sm.-Abb.*, *helicta Hbn.*) (49 g). Above unicolorous brown. Under surface lighter, with the middle ones of the rust-coloured lines on each wing joined into a circle, in which are placed on the forewing 3 or 4 eye-shaped spots with blue pupils and yellow iris (sometimes indistinct), on the hindwing 6 similar elongated spots with oval pupils. The egg of this species is yellow-green; it has quite fine, rough surface. Larva green with the head scarcely elevated, but with long anal points. Pupa obtuse, rounded, deep green, the wing-cases margined with whitish. The larva lives on grasses and is difficult to breed. Habits

as in *cornelius*. The butterfly is distributed in North America from New Jersey to the Gulf of Mexico and Texas.

E. cornelius *F.* (= *gemma* *Hbn.*) (49 f). Above grey-brown, hindwing at the distal margin with 2 indistinct, blackish double spots. Under surface grey-brown, finely irrorated with brown, with 2 indistinct, brown median lines. Hindwing with 4 small black double spots close to the distal margin, with very small silver spots before, beside and behind them, and also a faint violet spot, with slight silver gloss, at their proximal side. Egg yellow-greenish white with rough surface, yields the larva in April or August after 3–6 days. The summer form of the larva grey-yellow-brown, the spring form light green with light whitish yellow lateral and longitudinal lines. Pupa yellow-grey or light blue-green, head with two slight points. On grass. The larva shows a preference for the vicinity of water, and is consequently often very common in wet places, sometimes in company with *hermes*. The species is distributed in North America from West Virginia to Mexico and also occurs in Guatemala.

E. argentella *Btlr.* (49 g). Above brown, the distal margin somewhat darker. Hindwing at the anal angle somewhat produced and with 2 dark spots at the distal margin in cellules 3 and 4. Beneath somewhat lighter. Forewing with three dark transverse lines, hindwing with 2 transverse lines, the 2nd strongly curved inwards and outwards, the ground-colour behind it lighter. In cellule 3 and in cellule 4 a black eye-spot with obliquely placed pupil composed of scattered silvery scales and with red-yellow ring. Before the eye-spots are placed in cellules 5 and 6 two round silver spots and behind them in cellules 1 b and 2 silvery streaks curved in S-shape. From the Volcan de Chiriqui (Panama), also from Guatemala and Costa Rica. The examples from Costa Rica have a yellowish spot on the hindwing.

E. rogersi *Godm.* Similar to *argentella*, but the hindwing has only one black spot close to the distal margin in cellule 4, containing a light central dot. The anal angle is more strongly produced. On the brown under surface are placed 3 dark brown transverse lines and between the 2nd and 3rd a grey-yellow band, extending across both wings. At the apex of the hindwing a larger and a smaller eye-spot and some silver spots above them. From the volcano of Irazu in Costa Rica.

E. philodice *Godm.* Above reddish brown. Hindwing at the anal angle, as in the two preceding, obtusely produced, with an ochre-yellow stripe behind the middle and 3 dark brown spots before the distal margin. Beneath reddish brown, with 3 rust-coloured transverse lines. Between the two outer of these lines is placed a straight, light reddish yellow band, which begins in a point not far from the costal margin of the forewing and terminates obtusely before the inner margin of the hindwing. Before the distal margin of the hindwing a row of dark brown spots, the middle two the largest, all with sagittate silvery pupils. The ♀ is lighter and has the wings more rounded. From Costa Rica (volcano of Irazu).

E. nelsoni *Godm.* Above light olive-brown, the distal margin broadly dark brown, enclosing indistinct black spots. Beneath the forewing is brown, with 3 darker transverse lines, hindwing with straight whitish yellow band, which runs from the apex to the inner angle, a brown median line, before the middle of the distal margin 2 black eye-spots with sagittate pupils and on both sides of these similar silver markings. The ♀ is larger, has the median area of the hindwing above almost ochre-yellow, the dark distal margin is narrower and the black submarginal spots stand out distinctly. On the under surface the light band of the hindwing is absent. From Cerro de Zunil in Guatemala. Elevations of 6000 ft.

E. clinas *Godm.* Forewing with the apex truncate, the distal margin is bluntly angled at vein 5, posteriorly concave. Hindwing sharply produced at the inner angle, undulate at the distal margin. Above brown, forewing dark brown at the costal and distal margins, hindwing with 3 round black spots before the distal margin in cellules 3, 4 and 5. Beneath lighter reddish brown with 3 common transverse lines, namely 2 median and one submarginal, hindwing with 2 black, yellow-ringed ocelli with double silvery pupils before the middle of the distal margin, with 2 round silver spots at the anal angle and a sagittate silver spot between the median veins. Mexico (Guerrero, Sierra Madre del Sur). 7–8000 ft.

Pyracmon Group.

The ♂♂ have a dark scale-spot between and behind the median veins.

E. pyracmon *Btlr.* (♂ = *hilaria* *Godm.* [Biol. Amer. pl. 107, fig. 11, 12]). ♂ above reddish brown, with the distal margin darker, and with large dark brown scale-spot behind the median of the forewing. Hindwing dark brown, at the margin lighter, with 2 black spots bordered with reddish brown in cellules 3 and 4 near the distal margin. In the ♀ the forewing above has a straight, the hindwing an undulate dark brown median line, which is distally margined with red. Hindmargin of the forewing and apex of the hindwing darker brown. Anal angle reddish with 3 black submarginal spots. The under surface in ♂ and ♀ is yellowish brown with 3 dentate transverse lines on the forewing and 2 on the hindwing. Before the middle of the distal margin on the hindwing 2 black eye-spots in red-yellow rings and with silvery double pupils. Before these a glossy grey stripe accompanied by some silver spots at the costal margin and a silver line at the anal angle. From Mexico, Guatemala, Costa Rica, Panama. The ♂ figured in the Biol. Centr. Amer. pl. 107, fig. 11 and 12 under the name *hilaria* is referred by GODMAN in the text to *pyracmon* and the name *hilaria*, which is thus set free, is applied to another species (the next but one).

pephredo. **E. pephredo** *Godm.* Is similar to *cornelius* *F.* and chiefly differs from it in the ♂♂ having on the upper-side of the forewing a dark brown scale-spot, of which there is no trace in *cornelius*. This wing is also more produced at the apex. From Mexico (Guerrero and Cordova) and from the central valleys of Guatemala.

hilaria. **E. hilaria** *Godm.* ♂ above pale brown; forewing below the median darker striped by reason of the scale-spot, hindwing with 2 blackish spots at the margin, which are sometimes indistinct. Beneath lighter, dusted with brown, forewing with 3 undulate, hindwing with 2 rust-coloured lines, a row of silver spots at the margin and 2 black double spots in the middle of them, besides an ochre-yellow transverse line before them. The ♀ is similar to the ♂, but has sometimes on the upperside of the forewing two rust-coloured lines, on the hindwing one. From Mexico and Panama.

henshawi. **E. henshawi** *Edw.* Above reddish brown, the ♂ with the dark brown scale-spot of the preceding species behind the median of the forewing. The distal margin of both wings is faintly dusted with darker, in the middle of the distal margin of the hindwing two blackish spots. The body is black-brown. The under surface is similar to that of *E. cornelius*. 41 mm. — The egg is broader than high, almost spherical; at the base broadly flattened, of green colour and with very fine, little raised net-work on its surface. Concerning larva and pupa nothing is known. South Colorado and Arizona, distributed in the Rocky Mountains. Mexico (N. Sonora, Jalisco, Pinal, near Puebla, very common at 8000 ft. in a pine forest).

Mycalesoides Group.

mycalesoides. **E. mycalesoides** *Fldr.* (49 g). The wings are rounded and above unicolorous dark brown. The under surface is nearly as dark, the two median lines form large undulate curves, the inner is indistinct. The 3 marginal lines are not undulate, but run parallel with the smooth distal margin. On the forewing 2 eye-spots, in cellules 2 and 5, the former twice as large as the latter. They are black with white pupil and yellow ring. On the hindwing 4 similarly coloured eye-spots, two small ones in cellule 1 c, that in cellule 2 the largest. From Colombia (Bogotá). The figure is from FELDER's type in the Tring Museum. The species, which was described by FELDER as a *Pronophila*, was referred by THIEME to *Pedaliodes*. According to our figure it seems to me to belong to *Euptychia*. *mycalesoides* *Smith & Kirby* has nothing to do with this species.

Addenda.

lupita. **E. lupita** *Reak.* ♀ above brown with 2 narrow dark brown marginal lines. Beneath lighter with 3 marginal lines, the proximal one the broadest. Forewing with 2 brown transverse stripes between middle and base, a short stripe between them and a black eye-spot with light brown ring before the apex. Hindwing with 3 indistinct brown transverse lines through the middle and several shorter ones towards the base, a black eye-spot ringed with yellow-brown at the apex and two at the anal angle. Antenna rust-coloured. 32 mm. From Mexico (Vera Cruz and Orizaba).

moneca. **E. moneca** *Schaus.* ♀. Above brown with 3 dark marginal lines and a dot at the margin of the cell, the outer median line angled before the costa of the forewing, on the hindwing incurved before the middle, the inner median line indistinct, 2 eye-spots before the anal angle, the posterior the smaller. Beneath lighter brown, striated with darker, the lines all distinct. Forewing with a small eye-spot before the apex, hindwing with 6 ocelli, those in cellules 2 and 5 with silvery double pupils, a small similar one in cellule 4, smaller eye-spot with single pupils in cellules 1 b, 3 and 6. In the ♂ the eye-spots are smaller. 29—33 mm. From Castro in Parana and from Novo Friburgo.

burgia. **E. burgia** *Schaus.* ♀. Above brown, with straight, black distal median line, reaching to the anal angle of the hindwing, and with 3 marginal lines. Beneath olive-brown, the first transverse line angled and not reaching the costa of the forewing, the 2nd straight and distally bordered with lilac; 3 fine marginal lines. Forewing with 4, hindwing with 5 small ocelli. 40 mm. From Novo Friburgo. Will belong to the *Hermes* group.

borasta. **E. borasta** *Schaus.* ♂. Above brown with 3 marginal lines, a large and a small eye-spot at the anal angle of the hindwing with broad yellow rings and silver pupils. Beneath grey-brown, finely sprinkled with brown, with 2 brown median lines, the inner one curved distad on the forewing, the outer proximad. Distally to the latter is placed a white band, traversed by a brown shade. On the hindwing this becomes ochre-yellow at vein 3. On the forewing is placed in this shade an indistinct eye-spot, on the hindwing at the apex two black eye-spots with yellow rings and silver pupils and in the ochre-yellow part of the band, at the anal angle, 2 black spots with silver pupils. At the margin 3 dark lines as above. From Novo Friburgo (Brazil).

12. Genus: **Pindis** *Fldr.*

Approaches the genus *Taygetis*, but the eyes are naked, the palpi elongate, roughly scaled to the tip, the middle joint $1\frac{1}{2}$ times as long as the head, sparsely bristled, the terminal joint similarly formed, $\frac{1}{3}$ as long, obtuse. Wings broad, rather short. Forewing at the apex concavely truncate. Hindwing at the inner angle rather convex, the posterior part of the distal margin strongly dentate. The only species, which occurs in Mexico and Guatemala, is referred by most authors to *Euptychia*.

squamistriga. **P. squamistriga** *Fldr.* (= *Eupt. zabdi* *Bltr.*) (50 a). Above brown, forewing somewhat lighter at the apex. Beneath likewise lighter, dotted with brownish. The first transverse line is absent on the forewing.

the 2nd forms an obtuse angle on the hindwing. In the marginal area of the hindwing 6 small eye-spots, only the last but one somewhat larger. Rare in Guatemala (Choctum), not rare in West and Central Mexico.

13. Genus: **Cyllopsis** Fldr.

Likewise near *Taygetis*, the eyes naked. The palpus much more slender, its 2nd joint more than twice as long as the head, the terminal joint pointed. The distal margin of the forewing with rounded projection below the apex, that of the hindwing almost right-angled at vein 3 and obtusely angled at the anal angle. For the rest the distal margin of the hindwing is slightly undulate. The upper discocellular vein of the forewing is entirely absent. The genus has a similar range of distribution to the preceding, and likewise contains only one species, referred by many authors to *Euptychia*.

C. hedemanni Fldr. (= Eupt. ithama Bthr., ithamna Godm. [in tab. Eupt. vetones Godm.]) (50 a). ♂: *hedemanni*. above brown with a small black spot at the margin of the hindwing above the projecting angle. Beneath lighter, finely striated with brown all over, with 2 darker median stripes on both wings and a submarginal line on the forewing. A black eye-spot with double silvery pupil and surrounded by a light brown and a dark brown ring is placed in cellule 3 on the hindwing close to the distal margin. Beside it at the distal margin several silvery double dots. The ♀ is somewhat larger and bears on the upperside of both wings a rust-red line behind the middle, according to the figure in GODMAN also a second similarly coloured line before the middle. Rare. From Mexico, Guatemala, Costa Rica. Elevations of 2000—7000 ft.

14. Genus: **Oressinoma** Westw.

Distinguished from all the other American Satyrid genera by not having the costal vein of the forewing inflated, while on the other hand the median and submedian are strongly swollen at the base. The first median vein arises just behind the swelling of the median stem. The eyes are naked. The shape of the wings is longer than broad. The area of distribution is the west of tropical South America.

O. typhla Dbl. & Hew. (50 a). A species easy to recognize by the broad white band above and beneath, *typhla*. The basal area is above unicolorous and beneath marbled with brown and white. The dark brown distal margin is beneath divided for its entire length by a tri-coloured stripe, strongly dentate on the hindwing. This stripe is distally orange, proximally white, the two colours separated by a black line. Rather common in Colombia, Venezuela, Ecuador and Peru; rare in Costa Rica. — **sorata** Godm. & Salv. is a form of *typhla* in which *sorata*. the white band on both wings is narrower. In the distal margin are placed on the hindwing above white crescents, on the forewing a whitish line, which markings are also often indicated in *typhla*. From Bolivia (Calcan).

15. Genus: **Paramecera** Bthr.

Costal and median of the forewing inflated at the base, costal margin convex, distal margin slightly excised, upper discocellular short, middle discocellular longer and obliquely placed, behind the median in the ♂♂ a patch of dense, compact scales. Hindwing with the costa convex, distal margin sinuate, inner margin excised at the anal angle. Eyes somewhat hairy, palpus strongly haired, the terminal joint slenderer and directed more anteriorly than in *Euptychia*. Antenna short, the club pear-shaped, hollowed out on the underside. The single species is Mexican and resembles the European *Pararge megera*.

P. xicaque Reak. (= *Neonympha epiniphele* Fldr.) (50 a). Reddish brown, distal margin and the *xicaque*. spot behind the median darker. Forewing with 2 or 3 round black spots, hindwing with 5, the distal margin of the hindwing is reddish at the anal angle and has 2 dark brown, parallel marginal lines. Beneath the ground-colour is more yellowish with 2 strongly dentate median, a submarginal and 2 marginal lines. On the forewing 2 or 3 eye-spots, the first large, the last small, and 6 eye-spots on the hindwing, all of fairly uniform size. The ♀ is somewhat larger, otherwise similar to the ♂, except that the brown spot behind the median on the upperside is absent. The species was formerly very rare, but has recently been found more commonly. It inhabits the higher mountain regions of Mexico (Oaxaca, Jalapa, Puebla, Misantla, Bolannos, Maltrata, Guerrero, Vera Cruz, etc.). The figure is from FELDER's type in the Tring Museum.

16. Genus: **Satyrodes** Scudd.

Only the costal of the forewing is somewhat thickened or slightly swollen, the first 2 subcostal veins arise before the end of the cell, the upper discocellular is wanting. The margin of both wings is rounded. The eyes are slightly hairy, the palpus slender, beneath hairy, the 3rd joint short and pointed. One North American species.

S. canthus L. (= *euridice* Joh., *cantheus* Godt., *boisduvalii* Harr.) (50 a). The round brown spots *canthus*. of the upper surface are replaced beneath on both wings by a row of black, white-pupilled eye-spots ringed

with brown and yellow. The ground-colour of the under surface is yellowish grey with 2 brown transverse lines through the middle, the first straight, the second dentate. Between the two a short streak on the transverse vein. At the margin two yellow terminal lines and between these a brown one.—The egg is smooth, with whitish gloss, at the base flattened, above round. The larva deep green with red points on the head, yellow lateral stripe and light longitudinal lines. The pupa is more slender than that of *Enod. portlandia*, light grass-green with the edges of the wing-cases yellow and with yellow subdorsal and lateral lines on the abdominal part. The anterior end is pointed. The larva hibernates and feeds till the beginning of June on Cyperaceae, etc. The butterfly flies in July in wet grassy places and is locally common in the northern United States, but also occurs in Canada and the higher, cool mountain-valleys of Carolina.

17. Genus: **Coenonympha** Hbn.

The principal distinguishing character of this genus, which consists only of small butterflies, is that the costal, the median and the submedian of the forewing are all strongly swollen at the base. The palpus is densely clothed with erect hairs, the terminal joint porrect. Antenna short, but with relatively long club. Eyes naked. Both wings rounded at the distal margin. The species of this genus are distributed over the northern temperate zone of the Old and the New World, but the American species occur for the most part only in the western states of the Union. On the *Coenonympha* of the Old World cf. vol. I, p. 142—147, pl. 48; further vol. IX, p. 301.

- california.* **C. californica** Dbl. & Hew. (50 a). This species may be known by its white, unmarked upper surface, which is only somewhat dusted with blackish at the base. The under surface is finely dusted with brownish, especially on the hindwing, and shows a whitish dentate band through the middle and behind it 1 ocellus on the forewing and 3 on the hindwing. The ♀ is somewhat larger and beneath darker than the ♂. The butterfly occurs in a succession of broods, and is common in sandy and grassy places. — **galactinus** Bdv. (50 b) is the winter form of *california*. It is much lighter beneath and the eye-spots before the margin are much smaller. The egg is almost spherical, light coloured, with very low, fine ribs. Larva slender, elongate, with round head, green or brown, longitudinally striped. Pupa stout and short, obtuse, green or brownish, the wing-cases marked with oblique black stripes. The species is distributed along the whole western coast of the United States from *ceres.* Vancouver Island to California. — **ceres** Btlr. (= *eryngii* H. Edw.) is a form of *california* with the upperside pale ochre-yellow and the forewing beneath reddish with the base lighter. Beneath in addition the costal margin of the forewing and a broad band before the apex are grey, a transverse band behind the middle yellowish rust-coloured; the hindwing is pale grey with the base brownish and bears an irregular pale yellow median band and 2 black dots before the margin enclosed in light yellow rings. From California. — **pulla** H. Edw. is a form *pulla.* with the upper surface entirely fawn-coloured with blackish shading at the base. The under surface is dull brown with a reddish tone in the discal area. On account of the dark ground-colour the markings are only indistinct. From San Mateo, California. Appears to be a dark aberration of *california*, as only 1 example was known to the author.
- elko.* **C. elko** Edw. (50 b). Above ochre-yellow with whitish fringes and the inner margin of the hindwing whitish. Base somewhat dusted with blackish. On the under surface the forewing is somewhat lighter ochre-yellow, costal margin and apex finely dusted with brown, with a lighter half-band. Hindwing quite finely dusted with brown, with light yellow half-band at the middle of the costal margin. Above and beneath in both *ampelos.* sexes without eye-spots. From Nevada and Washington. June. — **ampelos** Edw. (50 b) is a form of *elko* which differs in the somewhat stronger brown dusting on the under surface and further in having the light band on the under surface prolonged or continued by separate spots. Distributed from Nevada westwards to Vancouver Island. — The egg is conical, yellow-green, the surface less ribbed than in *galactinus*. The young larva is similar to that of *galactinus*, with only slight differences in the colouring; when full grown it is 18 mm. in length, laterally yellow-green, with small white tubercles each bearing a short hair, posteriorly with 2 short, conical reddish tails. The pupa is shaped like that of *galactinus*, 10 mm. in length, green with black stripes and dots. The period from oviposition to the appearance of the imago is in the summer 49 days.
- ochracea.* **C. ochracea** Edw. (50 b). Above unicolorous, bright ochre-yellow, with the markings of the under surface showing through faintly in places. Underside of the forewing reddish yellow, before the apex with a small black, white-pupilled ocellus in a light yellow ring, and before this a light yellow band. The hindwing is dusted with yellowish brown and shows at the base 2 light yellow spots, in the middle a light yellow dentate band and before the distal margin one or sometimes several small, eye-shaped, black dots in light yellow rings. Distributed in the western part of North America from British Columbia to Arizona and eastwards to Kansas.
- brenda.* **C. brenda** Edw. Above light reddish yellow, without markings, beneath somewhat yellower; the forewing with a reddish transverse line beyond the middle, anteriorly straight, posteriorly curved. The hindwing has a similar line, which is anteriorly angled, posteriorly curved. Forewing with a large round black spot before the apex and a dot between medians 1 and 2. Hindwing with a more or less complete row of small dots. The ♀ is on the under surface darker, with an admixture of grey, the spot before the apex of the forewing has a white pupil and on the hindwing some of the dots are absent. From Los Angeles. *brenda* is regarded by

DYAR as a synonym of *ochracea*, by SKINNER on the contrary as a good species; as I do not know the species in nature, I leave the question undecided.

C. kodiak *Edw.* is above light yellowish grey with a pale yellow transverse band beyond the middle of both wings. The basal area of the hindwing is more brownish yellow-grey. The upper surface resembles that of *california* *Dbl.* except that *kodiak* is much darker. The same is the case on the under surface. From Alaska. Rare. — **yukonensis** *Holl.* has been described as a form of *kodiak*. The upper surface of the forewing is light ochre-yellow, the distal and costal margins grey, an indistinct white band behind the middle; hindwing dark grey, somewhat yellowish, with a dirty white, interrupted median band. On the under surface the forewing is dark ochre-yellow, sometimes chestnut-brown, shading off into grey before the apex and at the distal margin. The white band is here sharply expressed. A small eye-spot with white pupil before the apex. Hindwing blackish grey, distally lighter, with sharp white median band. A row of eye-spots is faintly indicated before the margin. The ♀ is somewhat larger and altogether lighter. Likewise from Alaska. July. It may be a separate species.

C. pamphiloides *Reak.* Authors are of different opinions as to the specific rights of this butterfly. Some consider it to be the same as the European *pamphilus* *L.*, others regard it as different. As I do not know the form in nature I cannot express a definite opinion. The entire upper surface and the under surface of the forewing are similar to those of *pamphilus* (vol. I, pl. 48 g). But according to the figure which HOLLAND gives in his Butterfly Book, the ground-colour of the hindwing beneath is not greenish grey but lighter, more yellowish grey, in the basal area are placed 2 light yellow spots, a dentate light yellow band runs through the middle, and before the margin there is a row of 6 round light yellow spots with black central dots. These dots are sometimes absent. The ♀ is larger than *pamphilus*. From Utah and California.

C. inornata *Edw.* (50 b). Above brownish ochre-yellow, in the middle somewhat lighter. Costa of the forewing and distal margin of both wings grey. Beneath the forewing shows a distinct ocellus and a narrow white band. The hindwing is grey with a short dentate white band through the middle and before the distal margin an indistinct red-yellow band, interrupted at the veins. This species is regarded by various authors as a form of the European *tiphon* *Rott.* (vol. I, pl. 48 h). But the latter has on the underside of the hindwing a row of six black, white-pupilled ocelli in light yellow rings and HOLLAND is therefore probably right in considering *inornata* as a separate species. From Montana, Minnesota, British North America and Newfoundland.

C. haydeni *Edw.* (50 b). One of the largest species. The body is dark brown, the antenna black ringed with white. The upper surface is brown, inclining to grey. The fringes of the forewing are somewhat lighter, those of the hindwing grey. The upper surface is without eye-spots. The under surface is lighter, yellowish grey. Before the distal margin on both wings is placed a thick silver line, which is interrupted at the veins. On the hindwing there is beside this line a row of 6 eye-spots, decreasing in size posteriorly, the last ocellus sometimes very small and then scarcely noticeable. These ocelli are black with red-yellow rings and white pupils. From Montana, Idaho, Wyoming and Colorado.

18. Genus: **Neominois** *Scudd.*

The costal and inner margins of the forewing are straight, the distal margin rounded. The costal margin of the hindwing forms an obtuse angle near the base. The costal vein of the forewing is strongly swollen at the base, the median on the other hand only somewhat thickened. The upper discocellular of the forewing is absent. The antenna is comparatively short, the underside of the palpus very hairy. The two forms of the genus occur in the mountainous western parts of the United States.

N. ridingsii *Edw.* (50 b). Upper surface grey-brown with a white macular band varying somewhat in breadth. The eye-spot at the anal angle of the hindwing is sometimes only punctiform or entirely absent. On the under surface the basal half of both wings is whitish, finely striated with brown, with 2 dentate brown transverse bands through the middle. In the ♀ the eye-spots on the upperside of the forewing are very large and there are more of them. I have before me a ♀ with 4 ocelli forming a continuous row; the first measures 4, the last 3 mm., the others are smaller. — The egg is whitish and almost spherical. The larva yellow-brown, much narrower posteriorly, with rounded head and dark nebulous lines. Pupa obtuse, well rounded, brown, at the anterior margin dark green, at the first spiracle a quite small, spinose, club-shaped process. It lies in a sandy hole on the ground. The butterfly occurs at elevations of 5—7000 ft. and is not rare locally. In Colorado and the western states. — **dionysius** *Scudd.* (= *ashtaroth* *Streck.*) is a somewhat larger form of *ridingsii*, differing in the lighter, brownish white colour of the basal part of both wings and the broader and lighter submarginal bands. On the under surface the median band of the hindwing is narrower and more sharply dentate and the proximally directed teeth of the brown border likewise more pointed. From Utah, Colorado and Arizona.

19. Genus: **Cercyonis** *Speyer*. (= *Satyrus* *Westw.* pt.)

The costal margin of the forewing is more strongly, the distal margin more weakly rounded, the inner margin in most species fairly straight. The distal margin of the hindwing is slightly undulate, the posterior part of the inner margin somewhat incurved. The palpus is long, projecting by more than the length of the head, densely haired, the eyes naked. The club of the antenna is thin and long, not sharply defined. The mid-tibia is scarcely spinose. The costal and median of the forewing are strongly swollen at the base, the submedian on the other hand only somewhat thickened. In the forewing the first 2 subcostal veins arise before the end of the cell. The ♂♂ of most species have a more or less distinct stripe of scent-scales on the upperside of the forewing behind the median. Some of the butterflies are of medium size, but some considerably smaller. They inhabit North America. Single species are very similar to European forms of the genus *Satyrus* and hence are referred to *Satyrus* by most American authors.

- pegala*. **C. pegala** *F.* (50 b, c). The largest species of the genus. Above brown, with broad ochre-yellow band on the forewing, on which are placed in the ♂ only one eye-spot, in the ♀ two. On the under surface the brown ground-colour is finely striated all over with dark brown and the hindwing has here 6 ocelli. Sometimes one of these is absent. The butterfly occurs in the southern part of the United States about as far north as to New Jersey. — **alope** *F.* (50 c) is the most widely distributed form in North America. It is somewhat smaller, and has in both sexes above and beneath two eye-spots on the forewing. The scent-scale spots on the upperside of the ♂ forewing in cellules 1a, 1b and 2 are distinct. The number of the ocelli on the hindwing varies. — *maritima*. **maritima** *Edw.* is a form similar to *alope* in which the under surface is darker and the band more orange-coloured. *texana*. It occurs in Long Island and Martha's Vineyard. — **texana** *Edw.* (= *incana* *Edw.*), a further form belonging here, has light brown ground-colour and ochreous bands. The spots on the underside of the hindwing are larger than in the other forms. From the extreme south of the United States. — **nephele** *Kirby* (50 c) was long regarded as a good species, but is now recognized as a dimorphic form of *alope*. In it the yellow band is much darkened by brown dusting and only to be recognized as a band in the ♂ on the underside of the forewing. On the upper surface of the ♂ and on both sides of the ♀ only the brownish yellow rings round the black eye-spots persist. It is the northern form of the species, and is of general occurrence in North America north of the latitude of New York from the Atlantic to the Pacific Ocean, but to the south of this only occurs on the heights of the Alleghany Mountains. — **olympus** *Edw.* (50 d) is a form similar to *nephele*, in the ♂ somewhat darker, in the ♀ somewhat lighter, and with only a few eye-spots on the underside of the hindwing. It is common in the States west of the Mississippi. — **ariane** *Bdv.* (50 c) is a small form, similar to *alope*, but darker. The eye-spots stand out distinctly on the upper and under surface of the wings. From British America, Oregon and the north-western part of the United States. — **boopis** *Behr* (50 d), a form belonging here, has on the upperside of the hindwing no eye-spots, on the underside only 1 or 2 indistinct ones. The scent-scale spots of the ♂♂ are distinctly visible on the upperside of the forewing between the 2nd median vein and the inner margin. Common on the Pacific coast in the states of Washington, Oregon and North California. — In *baroni*. the form **baroni** *Edw.*, which I also regard as belonging here, the yellow rings of the eye-spots above are almost suppressed, the under surface is more reddish brown, in consequence of which the transverse lines in the middle stand out distinctly. — **gabbi** *Edw.* is another form which is referable to this species. It is of the size of *nephele*, the ♂ dark reddish brown, the ♀ pale fawn-coloured. Beneath the distal half of the wings in the ♀ is pale grey-brown, the proximal half only a little darker. On the hindwing are placed here 6 black, white-pupilled eye-spots in yellow and brown rings, the 2nd and 5th larger than the rest and the last 3 in a straight row one above another. From Oregon and Utah. — The egg of *alope* is obtusely spherical, as high as broad, above strongly ribbed, the surface covered with minute pitting and of a lemon-yellow colour. The larva hatches in 14—28 days according to the temperature. The young larva is rose-coloured, hibernates small, afterwards becoming greenish, and when full-grown is 40 mm. in length, light green, whitish on the dorsum, with light yellow, dark-bordered lateral stripe and whitish, dark-shaded subdorsal line. It lives on species of grass. Pupa blue-green, finely marked with white. The butterflies fly in July and August in open woods and grassy places, are locally very common and visit especially the flowers of *Spiraea tomentosa*.
- meadi*. **C. meadi** *Edw.* (50 d) is an independent species, recognizable by its smaller size and the reddish yellow median area on the underside of the forewing. The ♂ is dark brown above, with 2 black eye-spots in broad red-yellow rings on the forewing in cellules 2 and 5, only the anterior having a white pupil. The area round the eye-spots is often more or less strongly dusted with red-yellow, especially the space between them. On the hindwing above there is only one ocellus. In the ♀ the eye-spots of the forewing above are placed on a red- or ochre-yellow band, which extends basewards into the cell, and then gradually passes into the brown ground-colour. — The egg is strongly ribbed at the sides, pitted above, rose-coloured. The larva is green, slender, the head rounded, light longitudinal lines on the back and yellow lateral and subdorsal line. It lives on grass. Pupa obtusely rounded, light green. The butterfly flies in July and August; it is rather local, but common in places, is fond of visiting Compositae, especially a species of *Senecio*. Localities: Colorado, Montana, Utah and Arizona.

C. oetus *Bdv.* (50c). Above grey-brown, the apex of the forewing lighter, fringes grey, 2 brown marginal lines; the forewing with 2 small round black-grey spots in yellow-brown rings, in the ♂ with brown scent-scale stripe. Beneath yellowish grey, the basal half finely striated with brown, forewing with 2 black-brown eye-spots with ochre-yellow ring and white pupil. The anterior eye-spot is very large, extending over 3 cellules, the posterior is smaller. Both wings with 2 brown marginal and a submarginal line. From North California *oetus*.

C. charon *Edw.* (50d). Above brown, forewing in the ♂ with 1 or 2 black spots without rings, in the ♀ lighter with 2 eye-shaped spots in ochre-yellow rings. The dark brown scent-scale spot of the ♂ extends into cellule 3. On the under surface there are in both sexes eye-spots with yellow rings and white pupils instead of the black spots. Both wings are beneath brown, finely striated with dark brown all over, hindwing with dark brown, dentate median line and a row of more or less distinct, small, black, white-pupilled eye-spots. — Egg, larva and pupa are almost exactly as in *meadi*. The longitudinal lines of the larva are commonly purer white, the pupa sometimes black-brown or black-grey. The butterfly flies near the ground in grassy places and visits especially composites. Flies in June to August. Locality: the west of North America, from British Colombia to New Mexico. — **sylvestris** *Edw.* (= *phocus* *Edw.*) is according to HOLLAND a form of *charon*, with the eye-spots on the underside of the hindwing indistinct. (KIRBY in his Catalogue has given *sylvestris* *Edw.* as the oldest name for *oetus* *Bdv.*) The figure called *sylvestris* on pl. 50d belongs to *sthenele*. *charon*.

C. paulus *Edw.* (50d). On the upper surface similar to *charon*, but beneath always with 2 eye-spots on the forewing in ♂ and ♀. The hindwing has also one or 2 eye-like spots on the upper surface. On the under surface the hindwing is grey in the distal third, finely striated with dark brown, proximally bordered by a dark brown dentate line. In this marginal area are placed 5 or 6 black eye-spots with white pupils and yellow and brown rings. From California and Nevada. *paulus*.

C. sthenele *Bdv.* (50e, the form erroneously called *sylvestris* on pl. 50d also belongs here). Above brown with 2 round black spots on the forewing, of which in the ♂ only the upper is pupilled with white, but in the ♀ both have white pupils and brownish yellow rings. The species is recognizable by the broad, dentate dark median band on the underside of the hindwing, which is strongly constricted in two places and both proximally and especially distally is broadly margined with whitish grey. In the marginal area a row of eye-spots, sometimes indistinct. From California. *sthenele*.

C. wheeleri *Edw.* (= *hoffmani* *Streck.*). Similar to *nephele*, but larger, especially the ♀. Ground-colour brown. The forewing above has 3 eye-spots. The apical eye-spot is double, consisting of a larger ocellus in cellule 5 and a smaller in cellule 4. Both are surrounded by a common narrow light yellow ring. In the ♀ these eye-spots are placed on a broad light brown band and 2 eye-spots are also present on the hindwing above before the anal angle. The under surface is not brown as in *nephele*, but in the ♂ light grey, in the ♀ light yellowish grey, finely striated with brown. Forewing with a dentate median stripe and 3 nearly straight marginal lines, all brown. Hindwing with a broken and a second dentate median stripe and 3 undulate lines at the margin. In the ♂ there is on the forewing a small 4th eye-spot in cellule 3, these eye-spots are surrounded in pairs by 2 yellow rings with brown exterior ring. In the ♀ these brown rings are particularly large, measuring 7 mm. in diameter. On the hindwing beneath there are 6 black eye-spots with white pupils in light yellow and brown rings. Nevada. *wheeleri*.

C. behrii *Grinnell*. Much smaller than the preceding, only 43 mm. in expanse. Brown, forewing with a black, white-pupilled apical ocellus, margined with somewhat lighter brown, a black spot in cellule 2, an indistinct submarginal and a brown marginal line. Hindwing with black anal spot. Beneath forewing wood-colour, marbled with darker, with 2 black, white-pupilled ocelli, an undulate brown median band, a broad band between the eye-spots and the distal margin and 2 marginal lines likewise brown. The hindwing is more mixed with grey. A broad band traverses the middle. In the marginal area is placed a row of 6 eye-spots, the 2nd and 5th large, the rest small. The 3rd eye-spot has no pupil, the others are all white-pupilled. The broad band behind the middle and the 2 marginal lines are as on the forewing. The ♀ measures 46 mm. and only differs from the ♂ in having the black spots on the upper surface all pupilled with white. From Tamalpais, a mountain in Marin County on the Bay of San Francisco in California. In the collection of the Californian Academy of Sciences. Collected by BEHR. *behrii*.

C. glaucope *Fldr.* (= *friedenreichi* *Stgr.*) (50d). Above brown with a broad red-yellow band on both wings, in which are placed on the forewing a double ocellus before the apex and a single one in cellule 2, on the hindwing sometimes a black dot in cellule 2. The under surface is lighter and striated with dark brown, on the forewing with the same band and eye-spots as above, but on the hindwing with a narrow, almost straight ochre-yellow stripe, extending from the middle of the costal margin nearly to the anal angle. Behind this stripe are placed on the costal margin 2 dark brown spots. Brazil (provinces of St. Catharina and Parana). — **boenninghauseni** *Foetterle* (50e) is only a form of *glaucope* in which the distal half of the hindwing beneath is not striated with dark brown and the light yellow median stripe is distally widened. From Itatiaya. *glaucope*. *boenninghauseni*.

gustavi. **C. gustavi** Stgr. (= *Satyrus g. aut.*) should perhaps be placed here. Above dark smoke-brown with a long light brown macular stripe before the margin, in which are placed on the forewing a black eye-spot before the apex and 1 or 2 small ones above the anal angle and also on the hindwing some black spots. The fringes are a mixture of light and dark grey, chequered with black. On the under surface the forewing is partly blackish, partly brownish grey or light grey with 4 short, streak-like yellow-brown longitudinal stripes. The ocellus in the first of these stripes is larger than on the upper surface. The hindwing beneath is dirty grey with sharply prominent light grey veins. The yellow-brown longitudinal stripes of the upper surface are here only very short. In the Bolivian highlands at 4000 m., discovered by GUST. GARLEPP.

20. Genus: **Oeneis** Hbn.

The chief distinguishing character of this genus is that none of the veins are swollen, but only the costal of the forewing is much thickened at the base. Otherwise the neuration is similar to that of the preceding genus. The costal margin of the forewing is fairly straight, the cell long and narrow, the apex produced, hence the distal margin rather oblique. The ♂♂ of several species have a stripe of scent-scales behind the median on the upperside of the forewing. The palpus is long, with bristly hairs, the antenna short, with the club gradually thickened. The butterflies are of medium or below the medium size and of yellow, yellow-brown or grey-brown colour, nearly all with the underside of the hindwing light and dark marbled and bearing a dark median band. Their area of distribution embraces the arctic zone and the higher mountains of the temperate zone in the northern hemisphere, both in the Old and the New World. Some species are common to both. Concerning the Old World *Oeneis* cf. vol. I, p. 117—121, pl. 40; also vol. IX, p. 311.

nevadensis. **O. nevadensis** Fldr. (= *gigas* Btlr., *californica* Bdv.) (50 e). The largest and most beautiful species of the genus. Recognizable by the reddish ochre-yellow ground-colour of both wings. The scent-scale stripe of the ♂♂ is very distinct. In the ♂ either 1 or 2 eye-spots are present on the forewing above and beneath. The second of these is placed in cellule 2. In the ♀ there are usually 2 eye-spots, but sometimes 3, the third placed in cellule 3. From California, Oregon, Washington and Vancouver Island. From 2000 to 7000 ft. — *iduna*. **iduna** Edw. (50 f) is a somewhat larger and lighter form of *gigas*. The ground-colour is of a much lighter ochre-yellow, especially on the hindwing, and also on the underside of the forewing. The brown striation on the under surface of the hindwing is much finer, so that the white ground-colour stands out much more strongly. The brown dentate lines are thinner and the distal margin narrower. From the coast-districts of northern California. — The egg is irregularly and shallowly ribbed, with pale rings. It hatches in 9 or 10 days. The larva is rosy ochre-yellow, with darker dorsal line and subdorsal stripes, between the two lighter longitudinal lines. On grass. Concerning the pupa nothing is known, as EDWARDS did not bring the larvae to pupation.

macouni. **O. macouni** Edw. This interesting species is quite like *nevadensis* Fldr. in size, colouring and markings, but is distinguished from it at once by the complete absence of the large brown scent-scale spot on the upperside of the forewing in the ♂, and further by the presence of a broad dark brown median band on the underside of the hindwing. The species has hitherto been found only in two localities in North America, being rather common at Nepigon on the northern shores of Lake Superior in Canada, from the end of June to the middle of July, in the damp, wooded grass-lands near the river of the same name. The second locality is Morley, Alberta, at the eastern foot of the Rocky Mountains, where the species was found by MACOUN. — The larva is figured by HOLLAND and is 35 mm. in length. The head is round with 4 vertical black lines, the body has on the dorsum several narrow dark longitudinal lines, at each side a broad subdorsal stripe and above the legs a dark lateral stripe with a light one above it. It lives on grass.

chryxus. **O. chryxus** Dbl. & Hew. (= *calais* Scudd.) (50 f). Similar to *nevadensis*, but smaller, the forewing somewhat more pointed, its costal margin marbled with light and dark, the distal margin in the ♂ consists only of a narrow brown marginal line, the scent-scale spot brownish grey. Forewing in ♂ and ♀ with 2 eye-spots and a small black dot between them, hindwing with a similar anal dot. On the under surface the anterior half of the forewing is finely striated with brown, and also the whole of the hindwing, on which 2 dentate stripes enclose a broad dark median area. — The egg is whitish, the larva grey-brown with dark nebulous lines, the pupa is rounded, anteriorly black-brown, posteriorly yellowish. The butterfly is widely distributed in the Rocky Mountains from Colorado, where it is met with at elevations of 9000 to 12000 ft., to the Canadian province of Alberta, where it occurs at from 4000 to 7000 ft. It flies at the end of June and in July. *calais* Scudd., which was described by the author as coming from Hudson's Bay, is now generally regarded as a synonym of *chryxus*.

ivalida. **O. ivalida** Mead. (55 f). This species is easily recognized by the brownish grey colour of the forewing and the whitish grey hindwing. A row of white-grey spots is placed before the distal margin of the forewing, with a small eye-spot before the apex. The under surface is also almost entirely white-grey. The costal margin of the forewing is dotted with brown to the subcostal, then in the anterior part of the cell marbled with brown, some brown streaks extending to the median. The hindwing is striated and marbled with brown with lines

about as in *chryxus*. The species appears only to occur in the Californian Sierra Nevada, especially near Lake Tahoe. According to EDWARDS the egg is distinguished by the somewhat curved ribs on its surface. Concerning larva and pupa nothing is known.

O. norna *Thly.* (= hilda *Quens.*, celano *Hbn.*) (vol. I, pl. 40c). According to EDWARDS 3 examples of this Palearctic species were found in North Alaska, of which STAUDINGER had determined one that was sent to him as probably a dark variety of *norna*, the condition of the specimen leaving him in some doubt. *norna* has on a brown ground a broad brownish yellow submarginal band across both wings, in which are placed 1 or more eye-spots. The under surface is rather like that of *chryxus*, but the median band of the hindwing is darker and more strongly dentate. Further observations as to the occurrence of this species in America would thus be desirable. Cf. vol. I, p. 119.

O. jutta *Hbn.* (= balder *H. Schöff.*) (50f). Another Palearctic species. The submarginal row of ochre-yellow spots consists on the ♂ forewing of small round spots, in the ♀ of larger oval ones, the number of the black dots in which varies from 1—4 on the forewing and from 1—2 on the hindwing. Beneath the entire hindwing and the apex of the forewing are grey, marbled with brown, the former with a greenish brown, dentate band. — The surface of the egg bears irregular, in part forked, longitudinal ribs. The larva is light yellow-grey with ochreous longitudinal stripes and rows of black dots and small dashes on the dorsum and at the sides. On grass, e. g. (in America) on *Iuncus articulata*. The pupa is whitish grey, at the abdominal end ochre-yellow. Whilst HOLMGREN says that in Europe *jutta* settles on pine-trunks, according to FYLES (in America) it always sits on the ground. When pursued it drops into the grass. It flies in June. In North America the species occurs in Maine, Nova Scotia and the Hudson's Bay Territory. In addition it is found in North Europe and North Asia. — **alaskensis** *Holl.* is a form of *jutta* with the wings more thinly scaled and transparent, and the spots on the upper surface more indistinct. On the under surface the wings are uniformly marked with small spots and streaks, so that on the hindwing there is no trace of the darker band of *jutta*. From Alaska. June und July.

O. uhleri *Reak.* (50f). Above reddish yellow-brown with dark veins and narrow brown distal margin. Forewing with an eye-spot before the apex and sometimes with 1 or 2 black dots below it. On the hindwing one or several black dots. Beneath the costal margin of the forewing and the entire hindwing are brownish white with a number of brown transverse streaks, which are grouped into several narrow transverse stripes; on the forewing are placed here 1 to 4 black spots, some of them with white pupils, on the hindwing a row of indistinct dots. — The egg is chalk-white, with 19 or 20 longitudinal furrows and with the vertex pitted. It hatches in about 10 days. The adult larva is about an inch long, stout, yellow-brown with grey dorsum and light longitudinal lines. It pupates free, among grass-culms near to the ground; and the pupa is ochre-yellow, darker on the dorsum. The butterfly flies from the end of May until July, in Colorado. — **varuna** *Edw.* (50f), originally described as a separate species, is regarded by most authors as a northern form of *uhleri*, by some even as a synonym. It is smaller, the colouring somewhat duller, the distal margin more broadly brown. On the under surface of the hindwing there is sometimes a dark brown band before the middle. But the number of eye-spots varies as in *uhleri*, MORRISON for instance having sent me among several *varuna* from Montana an example with 5 such spots on each surface of the hindwing. — According to EDWARDS the egg is chalk-white and has 18—20 ribs, some of them incomplete. The larva varies from whitish green to dirty yellow-brown, and is lighter on the back, with 3 rows of small black dashes and slate-grey subdorsal stripe. The pupa is ochre-yellow, the wing-cases light yellow-green. The larva pupates in a sort of cocoon formed in the sand. From Montana, North Dakota and the adjoining parts of Canada. — The preceding notes on the larva, pupa and transformation do not agree well with one another. One might therefore suspect in the two forms two separate species. Further investigations are needed to elucidate the matter.

O. alberta *Elw.* (50g). Forewing grey-brown above, in the ♀ strongly dusted with ochre-yellow, with an ochre-yellow submarginal band in which are placed 1—3 black spots or ocelli. Hindwing with the band more distinct, containing 1 eye-spot and 1 or 2 dots. Beneath the forewing is light brown-grey, towards the apex whitish, before this a short dark transverse band. Hindwing the same, with a broad, darker, irregular transverse band across the middle, which is bordered with darker at the margins. — The larva is dark olive-green or greenish slate-coloured with slightly lighter longitudinal stripes, on the back sometimes brown. The pupa is grey-green with dark anterior margin. The butterfly flies on dry, stony slopes, resting on the bare ground. It was discovered at Calgary in the province of Alberta (Canada). It flies in the middle of May.

O. taygete *Hbn.* (= bootes *Bdv.*) (50g). Above brown, the brownish ochre-yellow submarginal band in the ♂ is only present on the hindwing and in both sexes lacks the black spots. Beneath similar to the figured *alberta* in colouring and markings, but the dark median band on the hindwing is more strongly outcurved in its anterior part, forming an acute angle basewards in the middle. From Labrador.

O. subhyalina *Curt.* (= crambis *Frr.*, also *Möschl.*, oeno *Bdv.*, assimilis *Btlr.*) (50g). Dirty ochre-yellow to dark brown, mostly with obscure cinnamon-brown or ochre-yellow band and ochre-yellow spots in the cells.

Forewing without eye-spots or with 1 or 2 black ones, sometimes white-pupilled, hindwing without ocelli. Hindwing beneath ochre-yellow, marbled with grey and black-brown. Median band darker, bordered at each side by a light grey, sometimes darker band. Veins not dusted with white. Sometimes, however, the marbling of the hindwing is so much darkened as to obliterate the median band (*assimilis* *Bltr.*). — The egg is similar to that of *jutta*, but the ribs on the surface are finer. The larva is ochreous grey, with darker and lighter longitudinal stripes and rows of black spots. Localities: Newfoundland, Labrador, Alaska. Occurs also in North Asia (cf. vol. I, p. 120, pl. 40 f, under "*crambis*").

semidea. **O. semidea** *Say*. (50 g). The ♂ is unicolorous grey-brown above, the ♀ dark brown with darker marginal line, chequered fringes and small dark brown spots at the margin of the hindwing. The body is black-brown, the club of the antenna red-brown. The forewing beneath is brownish grey, towards the apex marbled with dark brown and whitish grey. The hindwing beneath is brown, marbled with dark brown in the basal and median areas, only the marginal area is marbled with whitish grey and brown, at the distal margin darker-spotted. — The egg is rather irregularly ribbed, grey-white, with silky gloss. The larva light green or yellow-brown with dark transverse shades on each segment and rows of blackish dots at the sides and on the back. Pupa black-brown with yellow-brown abdomen. The butterfly flies on rocky mountains, locally in large numbers, as on the peak of Mt. Washington in New Hampshire, also in Colorado and Labrador.

brucei. **O. brucei** *Edw.* (50 g) approaches *semidea*. It is, however, much more thinly scaled and hence semitransparent. Above like *semidea*, the under surface of the forewing also as in this. But the under surface of the hindwing is much lighter, the basal area has a whitish grey ground-colour, the median band stands out distinctly and the brown lines bordering it are outcurved at the costal margin (which is not the case in *semidea*). — The larva is ochre-yellow, shaded with brownish, with rows of darker dots. Pupa obtuse with the head truncate (much as in *semidea* and *uhleri*, but less than in *jutta*). The butterfly flies on grassy mountain slopes from the end of June to August, local. (Not on rocky peaks like *semidea*.) It is found in Colorado at elevations of 12 to 14000 ft., in the Canadian province of Alberta at 8 to 9000 ft.

beani. **O. beani** *Elw.* Likewise similar to *semidea* and thinly scaled. Above unicolorous light smoke-brown, the costal margin very narrowly light grey, dusted with black. The scent-scale stripe of the ♂♂ indistinct. Beneath the forewing is as above, but the costal margin narrowly and the apex broadly light grey, dusted with dark brown. The hindwing is light grey, densely dusted with black-brown without any trace of a band. Fringes chequered. Palpus entirely black. In the ♀ the hindtibia is thickened and at its extremity curved inwards. Found on rocky peaks near Laggan in Alberta at 8000—9000 ft.

katahdin. **O. katahdin** *Newcomb* (50 g). Above dark-brown, the distal third of the wings yellowish brown with blackish marginal line, fringes chequered with light and dark brown. A small black, white-pupilled spot before the apex of the forewing. Sometimes 3 or 4 such spots are present on the forewing, sometimes again all are absent. The scent-scale spot is faintly visible. Beneath the forewing is as above, but paler, costa and apex dotted with brown. The hindwing beneath has an irregular brown band through the middle, which is at first bordered with black, then with grey. The ♀ has the light brown colouring of the distal margin on the upperside more definite and usually 2 or 3 eye-spots. There is also a row of 5 whitish spots before the distal margin on the underside of the hindwing. The butterfly flies on Mt. Katahdin in Maine at altitudes of 4250—5000 ft., at the end of June.

daura. **O. daura** *Streck.* has been described from a single example, which was taken by MORRISON on Mt. Graham in Arizona. It is similar to the Siberian *fulla* *Evcrsm.* (cf. vol. I, p. 119, pl. 40 d), of a whitish ochre-yellow ground-colour (like *ivalida* [50 f]) with an angled brown median line and 3 small black spots, the first pupilled on the forewing. Hindwing at the margin broadly lighter and with a black dot in cellule 2. Fringes chequered. Beneath the hindwing is almost white, very finely and weakly marbled, with a somewhat darker, sharply defined median band. From Arizona.

21. Genus: **Argyrophorus** *Blanch.*

This genus is easily recognized by the dense silver gloss which almost entirely covers the wings above and beneath, or at least the upperside of the forewing. The costal and median are strongly inflated at the base. The upper discocellular of the hindwing is rather short. The wings are broader and less elongated than in *Oeneis*, the distal margin more rounded, the palpus less hairy. The antenna has the club comparatively short and thick. Although the butterflies do not even reach medium size, the first species is one of the most striking insects in the American fauna.

argenteus. **A. argenteus** *Blanch.* (51 a). Above entirely glossy silver-white without markings, fringes brown, body brown with white hairs. Forewing beneath likewise silvery white, the cell dusted with reddish yellow, with a small, round black spot before the apex, which in the ♀ contains a white central dot. Inner margin grey, fringes brown. Hindwing silver-white, basal half dusted with brownish white, with brown spots between, but with all

the veins remaining glossy white. Beyond the middle a row of brown spots, before the distal margin a row of brown crescents. The habitat is Chile, where the butterfly is locally common in the Cordilleras of the central provinces and on the Argentine borders in January and February, but is difficult to catch on account of its rapid flight. Only in the early morning it is more easily captured. The altitude at which it occurs is given as between 3000 and 7000 ft.

A. lamna *Thieme* (51 a). Much smaller than the preceding. Forewing above glossy silver-white with rather broad brown-black border, 6—8 mm. in breadth at the apex, 2 mm. at the anal angle. Fringes long and brown. Hindwing entirely brown, towards the base somewhat lighter. Beneath brown, the apex of the forewing and the whole hindwing sprinkled with grey-white atoms and with white longitudinal lines between the veins, on which are placed on the forewing two black dots and on the hindwing a row of 5. Proximally to these on the hindwing several further rows of small dots. From Bolivia. — To a local form of this species I give the name **angusta** *form. nov.* Instead of the broad brown distal margin of the forewing there is here only a narrow brown marginal line and before this a second line, only distinct in the anterior half of the wing. At the apex of the costal margin is placed a narrow brown triangle, its shorter side only occupying 2 mm. of the distal margin. Below this triangle there are 3 brown dots on a silver-white ground, at a distance of about 4 mm. from the distal margin. Fringes brown, spotted with white at the apex. On the under surface both wings have a sharply prominent white marginal line, the veins of the hindwing are likewise white, and the rows of dark dots very distinct. Likewise from Bolivia.

22. Genus: **Cosmosatyrus** *Fldr.*

Club of the antenna thin, moderately excised. Palpus thin, twice as long as the head, upper disco-cellular of the forewing short. Distal margin rounded, that of the hindwing slightly undulate. This genus was founded by **FELDER** on *leptoneuroides* and afterwards extended by **ELWES**.

C. leptoneuroides *Fldr.* (= *antarctica* *Reed*, *germainii* *Reed* [explanation of the plate]). Above brown, forewing in the ♂ somewhat dusted with rust-red in the middle, in both sexes an obscure, narrow rust-red submarginal band on the hindwing. On the under surface the forewing is grey-brown, basal and median areas red-brown, before the apex with a round black eye-spot with double white pupil and yellow ring. The hindwing is olive-brown to beyond the middle, then follows a dentate whitish yellow band and in the marginal area a row of 5 eye-spots, those in cellules 2, 5 and 6 black with white pupils and yellow and brown rings, the others, in cellules 3 and 4, white with black ring. At the distal margin is placed a narrow white stripe, which is divided into spots by the dark veins. The butterfly is rather common in the mountains of Chile at elevations of 3000 to 5000 ft. Flies at the end of January and in February. — **plumbeola** *Btlr.* is a local form of *leptoneuroides*, only differing in the presence of a bi-curved brown line on the underside of the forewing, bordering the red-brown median area. From Port Famine on the Straits of Magellan. — **duseni** *Stgr.* is a quite similar form to *plumbeola*, the differences according to **ELWES** being extremely slight; it was taken on the Rio Aysen in South Chile.

C. chiliensis *Guér.* (= *reedii* *Btlr.*) (51a). Upper surface in the ♂ unicolorous brown, fringes whitish grey; in the ♀ a round black spot is placed before the apex of the forewing and in its vicinity 4—6 small red-yellow spots. On the under surface the forewing is dark red-yellow to beyond the middle, the distal margin broadly grey, the black spot surrounded with ochre-yellow, hindwing grey-brown, marbled with dark brown and white. The butterfly is common in Chile from November to December and ascends from the coast to elevations of 4000 ft. — **monticolens** *Btlr.* is a form of *chiliensis* which chiefly differs in having a row of 6 black, whitish-bordered spots, placed on a broad brownish white submarginal band on the underside of the hindwing in cellules 1b—6. There are also here on the distal margin large dark brown spots between the entirely white veins. The butterfly is to be found on stony grass-lands in the higher mountain regions of Chile from 4500 to 6000 ft., but is difficult to catch on account of its rapid flight. — **williamsianus** *Btlr.* (= *Oeneis antarcticus* *Mab.* [according to **ELWES**]) is a small form belonging here, in which the median band on the underside of the hindwing is curved distally. The light band which follows is broader and instead of the eye-spots of *monticolens* there is here a row of 5 black dots, some of them indistinct. From Port Famine on the Straits of Magellan (*antarcticus* *Mab.* was discovered at Santa Cruz, a haven on the east coast of Patagonia at 50° south lat.). — **morania** *Berg* is a similar form to *williamsianus*, but has on the underside of the forewing an eye-spot with distinct white pupil, and on the hindwing instead of the row of black dots 2 black, white-pupilled ocelli in light yellow rings. The upper surface is unicolorous brown. It was taken in the interior of Patagonia at the source of the Rio Santa Cruz. — As **sajama** *form. nov.* (50 g) I add a similar form from Bolivia, which is perhaps the northern representative of the Chilean *chiliensis*-*monticolens*. The upper surface is brown, before the distal margin with a broad light ochre-yellow macular band, composed on the forewing of 6, on the hindwing of 4 spots. The first 3 spots on the forewing are long and narrow, in the 2nd is placed a black spot, the 4th and 5th are broader and long, the 6th also broad, but short. The 4 spots of the hind-

wing are basally pointed, distally broad. Beneath the forewing is brownish red-yellow, with a black spot before the apex, placed on a light yellow streak. Hindwing beneath similar to that of *williamsianus*, but the broad median band is bipartite, dividing into 2 bands, the outer one distally strongly dentate at the veins. Locality: Sajama in Bolivia. This form was collected by STÜBEL and in working out his captures I took it at the time for the similar *monticolens*.

milesi. **C. milesi** Weeks. Above brown, with a light brown band before the darker margin, occasionally also proximally bordered with dark. Before the apex of the forewing 2 black, white-pupilled ocelli with yellow rings close together, a similar smaller ocellus below them. Hindwing with black submarginal line, without eye-spots. The ocelli on the forewing are occasionally absent, in which case there is merely a black spot before the apex. The under surface is dark brown with slight golden gloss. Two dark lines traverse both wings, one in the middle, the other before the distal margin. The basal half of the forewing is here without markings. On the hindwing all the veins are white, between the 2 lines is placed a row of 4 or 5 elongate white spots, and the basal half of the wing is covered with short dark transverse streaks. From Sicasica in Bolivia.

quies. **C. quies** Berg. Above brown with a broad red-yellow band across both wings, reaching to the anal angle, on the forewing distally and proximally dark bordered and bearing before the apex a double eye-spot and in cellule 2 a single one. The middle of the forewing is likewise dusted with red-yellow. Hindwing without ocelli. Beneath the forewing is as above, the red-yellow band proximally somewhat lighter. Hindwing dark grey, striated with brown, with a broad whitish band across the middle. The distal margin of the hindwing is somewhat dentate. The ♀ is similar to the ♂, but the colouring is lighter and the markings weaker. From

plana. Patagonia and the southern part of Argentina. — **plana** form. nov. (51 a) is a form nearly agreeing with *quies* beneath, but with the 2 eye-spots on the upper surface placed in ochre-yellow rings, the lower without white pupils, in the middle of the wing with a row of 4 small red-brown spots. In the anterior half of the hindwing is placed an indistinct red-brown band. On the under surface this form differs from *quies* in having the basal half of the forewing reddish brown with 2 brown, angled marks in the cell. In addition the distal margin of the hindwing is almost smooth, while in *quies* it is dentate. From Uruguay.

statia. **C. statia** spec. nov. (51 a). Above unicolorous brown, without spots. Beneath grey-brown, the basal area of the forewing red-brown to beyond the middle, before the apex a round black eye-spot with 2 white pupils and an indistinct yellowish ring. Hindwing with 2 strongly curved, dentate dark brown transverse lines across the middle, formed merely of lunules. The ground-colour is grey-brown to the 2nd transverse line, the marginal area lighter and grey, or containing 2 brown spots in brown elongate rings in cellules 2 and 5, a red-brown, dentate submarginal line and a black marginal line. From Chile.

23. Genus: **Tetraphlebia** Fldr.

In the forewing the 2nd subcostal vein arises close beyond the end of the cell, the upper discocellular is short, the middle twice as long as the lower; the cells are strongly produced at the posterior end. The club of the antenna is thin, the palpus short and thinly haired. Distal margin of the hindwing rounded.

germainii. **T. germainii** Fldr. (= Sat. *promaucana* Reed). Dark brown, beyond the middle of both wings dusted with reddish brown, on the hindwing more weakly than on the forewing. Beneath the base and the costal and distal margins of the forewing are brown, the central area red-brown with brown median band. Before the apex a large black eye-spot with double white pupil and red-yellow ring. The hindwing beneath likewise brown with a broad white band beyond the middle of the wing, running parallel with the distal margin. This band is sharply defined proximally, but ill-defined distally. Rare at Chillan and in the Villacura Valley in Chile at elevations of 3000—4000 ft. According to REED not rare in the central provinces of Chile.

24. Genus: **Faunula** Fldr.

Build almost as in the preceding genus, but the hairs of the palpus are longer and the 2nd subcostal vein of the forewing arises much further from the cell.

leucoglenc. **F. leucoglenc** Fldr. Above brown, the forewing in the ♂ with raised dark scales in the disc, before the distal margin dusted with ferruginous. Beneath but little lighter, before the apex of the forewing a black eye-spot with thick white pupil and 2 dark transverse lines, which unite on median vein 2 and are here dusted with ferruginous. The hindwing brown, faintly spotted with ferruginous. This species has rarely been taken and is confined to high mountains in Chile, namely the Cordilleras at Condes near Santiago at altitudes of between 6 and 10 000 ft. and the pass from Lolco to Lonquimay at 8000 ft. Flies in January.

stelligera. **F. stelligera** Bltr. Above brown. Forewing with ferruginous streaks in cellules 2—4. Hindwing with three pointed ferruginous spots in the same cellules. Fringes dark grey. Beneath the basal half of the forewing is ferruginous, the distal half and also the costal and inner margins brown, finely striated with dark. Before the apex a rather large black eye-spot with double white pupil and yellow ring. Hindwing beneath brown,

with fine dark striation, a dentate black line behind the cell. Beyond this line the ground-colour is lighter with white rings and a curved row of 7 snow-white spots in black rings. Flies at high altitudes in the mountains of Chile and Argentina (4—7000 ft. Chillan, Lolco, Pulmari, Quillen, St. Martin).

F. johanna *spec. nov.* (51 a). Above brown. Forewing in the ♀ with a double eye-spot before the apex *johanna*, with ochre-yellow ring and 2 white pupils, and with a small blind eye-spot in cellule 2, also with yellow ring. Hindwing above without ocelli. Forewing beneath somewhat lighter than above, the eye-spots placed on a broad, somewhat lighter submarginal band, which is continued on the hindwing also and is proximally bordered by an angled brown line, distally on the forewing by a straight brown line, on the hindwing by one composed of crescents. In this band are placed on the hindwing 5 white dots. From Catamarca in Argentina.

25. Genus: **Neosatyrus** *Wlgr.*

Antenna with gradually thickened, pear-shaped club. Costal and median inflated at the base. Three of the subcostal veins run into the costal, two into the distal margin. The middle discocellular vein is angled.

N. ambiorix *Wlgr.* (= *minimus* *Btlr.*) (51 c). Above brown. Beneath lighter, forewing with red-yellow *ambiorix*, disc and double eye-spot before the apex, hindwing with a row of 6 white dots, 2 of which are ocellated. Common in Chile to the Argentine border at elevations of from 3000 to 6000 ft. Flies from December to February. From the description and figure I take *minimus* *Btlr.* to be a small example of *ambiorix*.

N. simplex *Btlr.* (*Argyrophenga* s.) belongs here according to ELWES. Above unicolorous brown. Beneath *simplex*, the forewing is brick-coloured orange, with dark costal and distal margins and pale brown inner margin; a large black eye-spot before the apex with 2 small white pupils and white ring. Hindwing pale brown with a small orange spot in the cell and a small lunular spot between the radials. The species was found at Chillan in Chile by EDMONDS in March and on the road from Loleo to Lonquimay by ELWES in January.

N. vesagus *Dbl.* (= *ochreivittatus* *Btlr.*). Above brown, forewing with a large red-yellow spot between *vesagus*, the radials. Hindwing unicolorous brown, or with 3 red-yellow spots between the median veins. Forewing beneath rust-coloured with brown margins and a large, round black eye spot with 2 white pupils and red-yellow iris. Hindwing brown with ochreous band across the middle. Chile. — **pusilla** *Fldr.* (*Homoeonympha* p. = *pusilla*, *violaceus* *Btlr.*) is a form of *vesagus* with a row of whitish yellow dots on the underside of the hindwing. According to ELWES *boisduvalii* *Blanch.* (51 c) and *hahni* *Mab.* probably belong here.

N. reedii *Btlr.* (51 c). Above olive-brown with cupreous gloss and dark margin. Beneath the forewing *reedii*, is tawny orange, before the apex a small black eye-spot with white pupil and orange ring. Hindwing brown, in the middle with a light violet-grey band, which is widened at the costal margin, distal margin striped with brown, basal part of the inner margin blackish. From Chile. — **fuscescens** *Btlr.* is a smaller form of *reedii*, the *fuscescens* forewing beneath smoke-brown, with a black dot instead of the eye-spot. From La Union in Valdivia.

N. humilis *Fldr.* (= *Stygnus* h.) (51 f). Above brown, without spots. Beneath lighter, forewing with *humilis*, 2 small black, white-pupilled eye-spots between the radials and the 3rd median vein, hindwing with 4 whitish yellow dots in the marginal area. Chile. Common in woods in Valdivia according to EDMONDS, rare at Quillen and at Lake Aluminé according to ELWES.

26. Genus: **Neomaenas** *Wlgr.*

Antennae with spindle-shaped club. Palpus projecting far beyond the head, beneath with long hairs. Wings with the margins entire, hindwing rounded. In the forewing the costal and median are inflated at the base. Differing from *Epinephele* chiefly in the absence of the scent-scale spot on the ♂ forewing.

N. servilia *Wlgr.* (♀ = *decorata* *Btlr.*) (51 c). Brown, forewing with a red-yellow band beyond the *servilia*, middle, the median area itself also somewhat dusted with red-yellow, a round black spot before the apex. Hindwing with narrow red-yellow submarginal stripe, which in the ♂ is broken up into spots. Beneath the forewing is almost entirely red-yellow with large double eye-spot before the apex. On the hindwing the median band is distally bordered with silver-white. Not rare at Valparaiso and other parts of Chile in February and March.

N. coenonymphina *Btlr.* is similar to *Epin. pales* above, but without the scent-scale spot. Forewing *coenonymphina*, beneath brick-coloured with brown margins and an apical ocellus. Hindwing in the basal half dark brown, bounded by an angled yellow line, disc yellowish with a black, white-pupilled eye-spot. Distal margin brown with dark dentate submarginal line. The ♀ is larger, the disc of both wings above ferruginous; on the under surface the eye-spot of the hindwing is absent. Rare in Valparaiso. December and January.

N. fractifascia *Btlr.* Above brown with a red-yellow spot in the middle of the forewing and a black *fractifascia*.

spot in a short red-yellow band before the apex. Hindwing likewise with a short band in which is placed at the anal angle a black spot. Beneath the hindwing is brick-coloured with a brown, dark-margined band, which in the middle is angled and broadly interrupted. In the marginal area 2 black spots at the apex and 2 between the median veins. Rare in the woods near the Baths of Chillan in Chile.

wallengrenii.

N. wallengrenii *Btlr.* Dark brown, with black apical spot. Forewing beneath yellow-brown with light yellow band and black, white-pupilled eye-spot before the apex. The posterior two-thirds of the hindwing are smoke-brown, divided by a reddish yellow band. Disc lighter, with white veins, distal margin brown. In woods below Chillan in Chile.

inornata.

N. inornata *Elw.* Dark brown, with a reddish tinge towards the base of both wings, and in the ♀ with a large black-brown spot before the apex of the forewing in an indistinct red-brown ring. On the under surface the forewing is brownish red-yellow with the costal and distal margins yellow-brown. Before the apex a double eye-spot in a yellow ring. Hindwing unicolorous yellow-brown. In the Baños de Cauquenes in Chile, in March.

edmondsii.

N. edmondsii *Btlr.* (*Argyrophenga* e.). Above glossy dark brown. Forewing rust-red in the cell, a black spot before the apex. Disc of the hindwing for the most part light rust-coloured with 3 pear-shaped black streaks. On the under surface the forewing is brick-coloured orange with the distal margin grey-brown, before the apex a black ocellus in a yellow ring. Hindwing olive-brown, with a broad sulphur-yellow longitudinal stripe extending from the base across the cell to the distal margin. 6 abbreviated yellow longitudinal stripes are placed on the veins, 2 before and 4 behind the first-mentioned stripe. The costal margin is likewise yellowish, the inner and distal margins grey. Rare, only 1 example in the British Museum, which was taken by EDMONDS in the woods below Chillan in Chile.

reticulata.

N. reticulata *Weym.* (51 c). Above brown. Forewing with 3 small red-yellow spots in cellules 2, 4 and 5 and four white dots before them in a row. On the hindwing a red-yellow band composed of 5 spots, some of which bear a black dot. The last spot at the inner margin has 2 dots. Both wings with white marginal line interrupted at the veins. Fringes brown. As may be seen from the figure the under surface is very characteristically marked. Locality unknown, probably South America. Coll. WEYMER.

tenedia.

N. tenedia *Weym.* (51 c). Above brown. On the forewing a large red-yellow spot covers the cell. A large black spot in an ochre-yellow ring is placed before the apex, sometimes showing 2 white pupils, a small ochre-yellow spot with black central dot in cellule 2, and some red-yellow dots beside it. The hindwing with a short red-yellow band in cellules 4 to 6. On the under surface the basal half of the forewing is entirely red-yellow, the black spot before the apex has 2 white pupils, its distal margin is brownish grey, and the entire hindwing is of this latter colour. From South Brazil.

27. Genus: **Epinephele** *Hbn.*

The antenna has an elongate, gradually thickened club. The costal and median of the forewing are strongly inflated and 2 subcostal veins arise before the end of the cell. The inner margin of the hindwing is more or less excised before the angle and in most species more elongated. The ♂♂ have a stripe of scent-scales on the forewing. Most of the species of this genus belong to the Palearctic fauna. Cf. vol. I, p. 137—142, pl. 46, 47. Some occur in India. Cf. for these *Maniola*, vol. IX, p. 306. The American species only inhabit Chile and the adjoining districts.

limonias.

E. limonias *Phil.* (= *janiroides* *Blanch.* [nec *H.-Schäff.*], *blanchardii* *Kirby*) (51 c). Above brown. Forewing with rust-red central area, which in the ♂ is divided by the dark brown scent-scale spot. In the ♀ the colouring is more red-yellow and a black apical spot is present. The under surface is lighter with distinct apical ocellus. Distributed and common in Chile. As the name *janiroides* had been already employed by HERRICH-SCHÄFFER for an *Epinephele* from Algiers it cannot be used for this Chilean species, and hence KIRBY chose the name *blanchardii*. But as the description of *limonias* *Phil.* agrees with this species the latter name must be restored. — **dryas** *Fldr.* (51 c), the figure of which is from FELDER's type in the Tring Museum, differs but little from *limonias*. From Chile.

edmondsii.

E. edmondsii *Btlr.* Above glossy brown. Forewing with the base and a band before the distal margin red-yellow, a row of 6 grey-brown spots across the middle and a black spot before the apex. Hindwing with red-yellow spot before the costal margin. On the under surface the forewing is red-yellow with grey, black-streaked margins and bi-pupilled apical ocellus. Hindwing beneath grey-brown, finely striated with black, with a somewhat darker median band distally margined with black, beside which are placed at the costal margin some white scales. From Chillan on the slopes of the Cordilleras (Chile). Rare.

monachus.

E. monachus *Blanch.* (= *valdiviae* *Fldr.*, *lugubris* *Btlr.*, *luctuosus* *Reed*) (51 d). Above unicolorous brown, with the fringes chequered with brown and white and an indistinct black spot before the apex of the forewing. Beneath the forewing is for the most part reddish brown, with a blind eye-spot, the hindwing brown,

striated with dark brown, with an oblique row of white dots. Very common in the mountains of Chile. The figure is from FELDER's type of *valdiviae*.

E. coctei Guér. (= *tragicus* Reed) (51 d). Above brown, somewhat dusted with rust-red and with some *coctei*, rust-red spots at the anal angle of the hindwing. The ♀ is rust-reddish to beyond the middle and has before the apex an eye-spot with double pupil. On the under surface the forewing in both sexes is red-yellow with a similar eye-spot, the distal margin and the hindwing lighter brown, the latter with a lighter band beyond the middle. According to ELWES locally common in the Chilean mountains.

E. tristis Guér. Somewhat larger than *coctei*. According to the figure in „Voyage Coquille“ above uni- *tristis*, colorous dark yellow-brown with the veins lighter and a small, round, pale yellow spot at the end of the cell on the forewing. On the under surface, which is not figured, according to GUÉRIN's description there is a yellowish white line on the hindwing, anteriorly expanding into a large spot of the same colour. According to ELWES the species is locally common in Chile. — **pales** Phil. (51 d). Perhaps a form of the preceding. Above *pales*, grey-brown with 2 small red-yellow spots at the margin of the hindwing. Forewing beneath red-yellow, costal and inner margins narrowly yellow-grey, distal margin broadly yellow-grey, a large eye-spot with double pupil before the apex. Hindwing beneath yellow-grey with the margin lighter. Chile (Valdivia).

E. flora Phil. (= *Pedal. oaxes* Btlr., *Stibomorpha tristis* Btlr.) (51 d). Above brown with 1 or 2 red- *flora*, brown spots, which, however, may also be absent. Fringes chequered with yellow and brown. Beneath: forewing spotted with red-yellow and brown, its costal margin marbled with black and white. Hindwing marbled with dark brown, with a yellow spot in the middle, an undulate white transverse band and a white spot at the costal margin. Province of Valdivia (Chile). PHILIPPI described the species as a *Satyrus*, BUTLER first as *Pedaliodes*, then as *Stibomorpha*. On account of the basally inflated median I place it here.

E. nycteropus Reed (51 d). Above brown, in the ♂ with dark brown scent-scale patch, in the ♀ with *nycteropus*, dark red-yellow median spot on the forewing. On the hindwing some red-yellow submarginal spots. Forewing beneath red-yellow, distal margin broadly, costal margin narrowly grey-brown, a round apical ocellus with 2 white pupils in ochre-yellow ring. Hindwing grey-brown with a dentate white median stripe. In the middle of the lighter marginal area 2 light yellow spots. Differs also from *flora* Phil., to which it bears some resemblance, in not having either the fore- or hindwing dentate and in the more produced apex of the forewing. Rare and apparently confined to the coast-region of Central Chile.

E. poliozona Fldr. (51 d). Above unicolorous brown. Beneath brownish red-yellow with the margins *poliozona*, of the forewing grey-brown, a blind apical ocellus, hindwing with a light lilac submarginal band. On this is placed in cellule 2 and in cellule 5 a black dot. Chile.

E. gyrtone Berg. Above brown, the ♂ with a double eye-spot before the apex and without eye-spots *gyrtone*, on the hindwing. In the ♀ in addition a 2nd small eye-spot in cellule 2 of the forewing and 5 on the hindwing. Beneath yellowish grey, with a lighter band before the distal margin, partly white on the hindwing, on which are placed the black, white-pupilled and yellow-ringed ocelli, in the ♂ 2 on the forewing and 4 on the hindwing, in the ♀ 3 on the forewing and 5 on the hindwing. The first eye-spot on the forewing is larger and bi-pupilled. The band is proximally and distally bordered by a dark line. 39—45 mm. Found in the south of the province of Buenos Aires (Sierra Tandil).

E. imbrialis Weeks. Above bronze-brown. On the forewing a dentate dark brown line runs from the *imbrialis*, apex to the submedian and from there back, touching the discocellular, to the middle of the costal margin. In the triangle thus formed is placed before the apex a black double eye-spot with 2 silvery pupils and light brown ring. The hindwing has a fine dark brown submarginal line and only occasionally a small eye-spot with single pupil at the anal angle. The under surface of the forewing is as above, only much lighter, the eye-spot is larger and has a yellowish white ring. The apex is dusted with grey. The hindwing is grey beneath, strongly dusted with brown, with a broad grey band, proximally bordered with brown, before the distal margin. Sometimes a row of brown spots is present in the middle. Thus the species is apparently very variable. From Bolivia, Alezuni district.

28. Genus: **Erebia** Dalm.

Only the costal of the forewing is strongly inflated at the base. Of the subcostal veins 2 usually arise before the end of the cell, sometimes only one. The 4th subcostal vein runs into the apex of the forewing. The antenna has the club distinctly prolonged. The palpus is anteriorly clothed with long, stiff hairs, above with shorter hairs. The distal margin of both wings is rounded. The *Erebias* are mostly small dark brown butterflies, scarcely reaching medium size. Their range of distribution embraces the whole Palearctic and Nearctic Region. They are mostly mountain butterflies, inhabiting the alpine regions of Europe, Asia and America. Only a few species descend to the hills. In comparison with the Palearctic Region the number of the American species is small. For the habits and life-history of *Erebia* cf. further vol. 1, p. 94 and 95.

- discoidalis*. **E. discoidalis** Kirby (51 e). Above dark brown, the distal half of the forewing red-brown, the two colours shading into one another; an obscure black eye-spot with whitish pupil before the apex. Beneath the forewing is red-brown, the margins striated with dark brown. Basal half of the hindwing brown, distal half grey, the whole with darker striation. From Hudson's Bay. Also occurs in Siberia, cf. vol. I, p. 111.
- fasciata*. **E. fasciata** Btlr. (vol. I, pl. 35 e). Above brown, forewing distally red-brown as in *discoidalis*. Beneath the forewing is rust-coloured, whitish at the apex, with 3 brown bands, namely a basal, a median and a marginal. The median band is undulate and at the costa broader; all these are bordered with rust-colour. Hindwing whitish grey, with 3 similar, but red-brown bands, the middle one dentate at both sides. 51—58 mm. Localities: arctic North America, East Siberia. Cf. vol. I, p. 103.
- rossii*. **E. rossii** Curt. Dark brown, with the fringes somewhat lighter. Forewing before the apex with red-brown spot, in which are placed 2 black dots. Sometimes below these 2 smaller red-brown spots, each with a black dot. On the hindwing sometimes three similar spots with indistinct dots. Beneath the forewing is red-brown with dark brown margins and sometimes with white-pupilled eye-spots. Hindwing dark brown, dusted with whitish grey, with obscure darker median band, before the discocellular a white spot and beyond it, before the distal margin, 2 or 3 white dots. Localities: arctic North America and Siberia. Cf. vol. I, p. 109.
- mancinus*. **E. disa** Thnb. **mancinus** Dbl. (51 e). Above brown. Forewing with a red-brown band before the distal margin, composed of 4 spots placed close together. Each spot contains a black dot, mostly with white centre. Fringes chequered with brown and white. Hindwing unicolorous brown. Beneath somewhat lighter, the apex of the forewing and the distal margin of the hindwing dusted with grey. The band of the forewing is broken up into 4 separate red-yellow spots, only the first 2 still connected, the black dots in them larger than above. This butterfly is found in the mountains of Alaska and British Columbia. On the type-form *disa* cf. vol. I, p. 109, pl. 37 h.
- vidleri*. **E. vidleri** Edw. This species is near the Siberian *sedakovii* Ev. (cf. vol. I, p. 105, pl. 37 e), resembling it in size, colour and markings; but according to ELWES the difference in the genitalia is so great that the two species cannot be regarded as identical. The band on the upperside of the forewing is yellowish brown and runs straight across the wing, enclosing three small dark brown eye-spots, of which the first 2 have white pupils. The band of the hindwing is shorter than in *sedakovii*, only reaching the middle of the wing and containing only 2 brown spots, the upper very small. On the under surface the band of the forewing does not reach the costal and the one on the hindwing is very similar to that of *aethiops* (vol. I, pl. 37 e) or *sedakovii*. Found by Capt. VIDLER in the mountains beyond Lake Seton at Lilloet on the Fraser River, British Columbia. Also occurs in Washington (according to DYAR).
- callias*. **E. callias** Edw. (51 f). Above brown, before the apex of the forewing with a red-brown spot, in which are placed 2 small, white-pupilled ocelli. Beneath the forewing is red-brown with the costal and distal margins grey and with the eye-spots as above. Hindwing grey, finely striated with brown, with several dark transverse stripes. Common on high mountains in Colorado and New Mexico. It is the American form of the Palearctic *tyndarus* Esp. (cf. vol. I, p. 113, pl. 37 i).
- epipsodea*. **E. epipsodea** Btlr. (= *rhodia* Edw.) (51 e). Above brown with 4 or 5 black, white-pupilled eye-spots on the forewing and 3 or 4 on the hindwing, all broadly surrounded with red-brown. Beneath the eye-spots are exactly as above and the hindwing has a broad, curved blackish median band. — The egg is suboval, chalk-white. The larva stout, cylindrical, with rounded head, and of a dull yellow-green colour; the pupa is brownish white, spotted with brown. The butterfly appears in 10 days. It is common in the mountains of British Columbia and its range extends from New Mexico in the south, where it flies in high-lying districts, to Alaska in the north. — **brucei** Elw. (= *sineocellata* Skinn.) is a smaller form of *epipsodea*, with the eye-spots absent and the red-brown macular band almost obsolete. It occurs on high mountain peaks in Colorado at altitudes of 12000 ft.
- sofia*. **E. sofia** Streck. (♀ = *ethela* Edw.) (51 e). Above dark brown, forewing with a smooth-edged submarginal band of 6 red-brown spots, hindwing with 5 similar spots, of which the last 2 are more isolated. On the under surface the forewing is red-brown in the middle, the band is as above, but the first 3 spots are light yellow, the last 3 red-yellow. The hindwing has a white spot in the cell and 3 whitish spots at the apex, below them 2 white dots. The butterfly is still rare in collections and has been found at Fort Churchill in British North America, in the Yellow-stone National Park and some other localities in Colorado. — **alaskensis** Holl. is a form of *sofia* with fewer spots on the wings. The forewing shows only 3 on each surface, the hindwing only 2 on the underside. In Eagle City and at American Creek in Alaska, taken in July.
- youngi*. **E. youngi** Holl. Above velvety dark brown, forewing with a short submarginal band composed of red-brown spots. Each spot contains a black dot. The hindwing has a similar row of spots, but more isolated. The under surface is paler. On the forewing the band is somewhat more continuous even than above. Across

the middle of the hindwing runs a broad, curved dark band, bordered with black at both sides, to which follow a grey and then at the distal margin a dark brown band. The black dots of the upper surface are here only faintly indicated. The ♀ is somewhat lighter above than the ♂, beneath somewhat more sharply marked. 33—35 mm. From Alaska.

E. magdalena *Streck.* (51 c). Upper and under surface of both wings unicolorous black-brown, without markings. Has hitherto been found only in Colorado at altitudes of from 10 to 14000 ft.

E. patagonica *Mab.* (51 c). Above dark brown with a brownish red submarginal band on both wings, which, however, does not reach the costal and inner margins. Beneath the forewing is red-brown with black veins and a small black, white-pupilled eye-spot before the apex. Hindwing brown, striated with dark brown, through the middle a dark brown dentate line, accompanied distally by a narrow light brownish band; two black, white-pupilled ocelli in cellules 2 and 3. From Patagonia.

29. Genus: **Manerebia** *Stgr.*

Antenna thinner and shorter than in *Erebia*, the club but little thickened and scarcely hollowed out. Wings above without markings. Forewing beneath with an eye-spot above the anal angle or some white dots before the distal margin. The hindwing has a curved, dark transverse line in the basal part and 2 others, undulate or dentate, before the distal margin, with light dots or small eye-spots between them. From Bolivia and Peru.

M. cyclopina *Stgr.* (= *Lyman. varola Schaus*) (51 f). Above uniform black-brown, beneath somewhat lighter, the apex of the forewing sprinkled with light grey, with a black, white-pupilled and brownish-margined eye-spot in cellule 2 and sometimes a smaller eye-spot above or below it; further with 2 or 3 white dots before the apex, a dentate dark transverse line before the margin and an indistinct line before the eye-spots. Hindwing brown-grey, at the margin sprinkled with grey and with 3 dark transverse lines, a larger yellow-ringed eye-spot and a smaller one below it before the anal angle. Towards the apex 1—3 white dots. From Peru and Bolivia. — Whether **cyclopella** *Stgr.* (51 f) is a seasonal form of the preceding or a separate species is not yet settled. It differs in having the 2nd and 3rd transverse lines on the underside of the hindwing nearer together and the eye-spot almost entirely yellow. From Bolivia. Equally uncertain is the specific right of **cyclops** *Stgr.*, in which the hindwing above is not sprinkled with grey at the distal margin and which differs from the other forms in having the band between the 2nd and 3rd transverse lines on the underside of the forewing much constricted. From southern Bolivia (Bueyes).

M. typhlops *Stgr.* Above dark black-brown. Beneath more brownish with 2 weakly dentate dark brown transverse lines before the distal margin of both wings, between which are placed some white dots. The number of these dots varies on the forewing from 3 to 7, on the hindwing from 2 to 5. 34—35 mm. From the province of Yungas in Bolivia. — **thyphlopsella** *Stgr.* is a form which only differs in its smaller size (28—29 mm.) and in having the under surface, particularly that of the hindwing, suffused with much lighter grey. From Tanampaya in Bolivia.

30. Genus: **Idioneura** *Fldr.*

Forewing rather elongate, its distal margin rounded, only the costal vein inflated at the base, the middle discocellular of the forewing straight, the lower proximally angled, these two veins form in the hindwing almost a straight line. The eyes are naked. Only one Colombian species.

I. erebioides *Fldr.* (51 f). The brown colour of the upper surface becomes darker towards the base. The fringes are grey. On the hindwing above are placed in cellules 3 to 5 three distinct black, white-pupilled ocelli in red-yellow rings. The under surface is somewhat lighter brown. Across the middle of both wings runs a dark brown dentate transverse line and before the distal margin are placed 2 smooth lines. On the hindwing in cellules 2—4 three short white longitudinal streaks, which are pointed at both ends. From Bogotá (Colombia), 2500 m. As **moderata** *form. nov.* I add a form of *erebioides* which has only one eye-spot on the upper side of the hindwing, in cellule 3, and the white longitudinal streaks on the under surface entirely absent. From Bogotá.

31. Genus: **Pseudomaniola** *Weym.*

The costal of the forewing is strongly, the median more weakly inflated; the 2nd branch of the subcostal arises far beyond the end of the cell, the middle discocellular of the forewing is semicircularly incurved, the lower nearly straight. In the hindwing the middle discocellular is slightly incurved. The palpus is densely covered with long hairs, the antenna short, with broad, sharply defined, shovel-shaped club. The two species occur at great altitudes in the Bolivian highlands.

P. euripides *Weym.* (51 f). Above light brown, distally with greenish reflection. On the forewing a broad ochreous band, in which are placed before the apex 2 brown spots and below them sometimes 2 further

brown dots. The hindwing has 3 large red-yellow spots in cellules 2—4. On the under surface the ground-colour is darker brown, without the greenish reflection, the band red-yellow, the 2 larger black spots white-pupilled, joined together and surrounded by a broad light yellow ring. The hindwing is irrorated with dark brown, with broad, lighter border occupying a third of the wing. A dark brown band separates the two colours. Before the distal margin in cellule 2 a dark brown, white-centred spot. At Portuguelo de Corocoro and Sica-sica at 3600 to 4600 m. (Collected by STÜBEL).

eleates. **P. eleates** Weym. Above brown, with two small red-yellow spots on each wing placed in cellules 2 and 3 not far from the distal margin, on the forewing distinct, on the hindwing more indistinct. Beneath likewise brown. Forewing with black, white-pupilled eye-spot before the apex, surrounded by a light brown ring which is posteriorly prolonged into cellule 3. The border of the hindwing is yellowish brown, occupying a quarter of the wing, and contains a row of brown crescents. Only one example (a ♂) was collected by STÜBEL, at Tacora in Bolivia; this is now in the Zool. Museum in Berlin.

32. Genus: **Calisto** Hbn.

This genus differs from all the other American Satyrid genera in that all the subcostal veins of the forewing arise beyond the end of the cell. The costal and median of the forewing are strongly inflated. The middle discocellular of the forewing forms a right angle, the posterior arm extending far distad, so that the cell is much longer posteriorly than anteriorly. The inner margin of the hindwing is more or less deeply excised before the inner angle. In most species the ♂♂ have a silky scent-scale spot on the upper surface. The butterflies are mostly small or below medium size. They inhabit the Antilles; a single species is said to be found on the continent of America, but this seems to need confirmation.

zangis. **C. zangis** F. (= *agnes* Cr.) (51 f). Above brown, forewing in the ♂♂ with a large, round, velvety dark brown scent-scale spot in the middle. The hindwing is reddish brown in the posterior half, with a small black spot at the anal angle. Under surface brown, forewing with a large eye-spot before the apex near the costal margin. This is black with ochre-yellow ring and double white pupil. On the hindwing a much smaller eye-spot before the anal angle. The distal half of the hindwing is lighter brown. The butterfly is common on Jamaica, both in the plains and the mountains, where it ascends to 6000 ft. One example was taken according to LATHY in Demerara, British Guiana. The further localities which have been given, "Pennsylvania" in CRAMER (Uitl. Kap.) and "Carolina" in GODART (Encyclopédie) and in KIRBY's Catalogue are in all probability erroneous, as HOLLAND and DYAR do not cite the species in their works.

nubila. **C. nubila** Lathy (51 f) is quite similar to the preceding species, but differs in the absence of the velvety scent-scale spot of the ♂♂. The upper surface is entirely blackish brown, distally paler, with a black spot at the anal angle of the hindwing. On the under surface the cell of the forewing is bright red-brown, the hindwing likewise red-brown, at the anal angle orange-coloured, with a larger eye-spot in cellule 2, which is of an orange colour, and some small white spots beside it. The ♀ is not known. From Porto Rico.

archebates. **C. archebates** Mén. Above cupreous brown, with a velvety spot on the forewing extending from the inner margin to the cell. Beneath brown. Forewing with black, white-pupilled, yellow-ringed ocellus, hindwing with light yellow band across the middle, which is widened at the inner margin. Behind this an eye-spot, like that on the forewing, and two white dots beside it. From Haiti. Very rare. Only in the collection of GODMAN and SALVIN and in the St. Petersburg Museum.

pulchella. **C. pulchella** Lathy (51 g). Above dark brown, in the ♂ with the velvety spot on the forewing as in the other species and a black spot at the anal angle, bordered with light yellow. The ♀ has on the hindwing a large orange-brown spot in the posterior part of the distal margin before the anal angle, traversed by a dark brown line. The under surface is similar to those of *zangis* and *nubila*, but the basal half of the hindwing is almost entirely reddish orange, before the eye-spot on the hindwing there are 3 white dots in a row, one above another, and behind it a row of red-yellow spots. On the forewing the 2nd white pupil of the eye-spot is removed basad and placed in the yellow ring. From Haiti. **tenebrosa** Lathy is a female form of *pulchella* in which the large orange-brown area before the anal angle on the upperside of the hindwing is absent. Likewise from Haiti.

herophile. **C. herophile** Hbn. (51 f). Above brown, in the ♂ with a dark velvety spot on the forewing. Beneath grey-brown with 2 undulate median and 2 broad, finely dentate submarginal lines, a red-yellow triangle at the base of the forewing, with a large eye-spot on the forewing and a somewhat smaller one on the hindwing and before the latter a row of 4 white dots. From Cuba.

hysius. **C. hysius** Godt. The smallest species of the genus, with an expanse of only 24—28 mm. Above dark brown, in the ♂♂ with large, velvety blackish spot on the forewing. Beneath brown, forewing irrorated with ochre-yellow, with the cell filled up with brick-red, a brown median line, distally margined with yellow, 2 submarginal

lines and a large yellow-ringed apical ocellus with double pupil. Hindwing brown, densely sprinkled with ochre-yellow. In addition to the 3 transverse lines of the forewing a further transverse line is also present near the base. A small eye-spot in cellule 2 and above it two white dots. From Haiti. Also occurring in Jamaica, according to an example in coll. STAUDINGER. — **confusa** Lathy (= *lysia* Mén.) (51 g) is a form of *hysia* which differs above in having a small ochre-yellow spot placed at the anal angle of the hindwing. On the under surface the yellow transverse line before the eye-spot of the forewing only extends to vein 2. The two brown transverse lines before and in the middle of the hindwing are distally distinctly bordered with white, the two brown submarginal lines terminate at the anal angle in a black spot and the space between them is filled up with white in the posterior part of the wing. The eye-spot of the hindwing is also somewhat larger than in *hysia*. From Haiti.

33. Genus: **Steroma** Westw.

A genus easy to recognize by the shape of the wings. The distal margin of the forewing is weakly, that of the hindwing between the veins strongly excised. Below the apex of the forewing the distal margin projects obtusely. The inner margin of the hindwing is deeply excised before the inner angle, so that the angle itself is produced into a lobe. The costal margin of the hindwing is likewise deeply excised in the middle and then forms at $\frac{2}{3}$ of its length a broad, rounded tooth, which is covered by the inner margin of the forewing. The costal and median of the forewing are strongly, the submedian somewhat less strongly inflated at the base. One subcostal vein arises before the end of the cell of the forewing. The ♂ has on the forewing a velvety scent-scale spot. The butterflies occur in the high mountains of tropical America.

S. superba Btlr. (51 g). Above black-brown, at the margin reddish, the ♂ with a large silky scent-scale spot in the middle of the forewing. Beneath the forewing is glossy copper-brown, at the apex marbled with dark brown. The whole hindwing similarly marbled. At the costa of the hindwing is placed a silvery spot, in the middle another and before the distal margin a row of ochre-yellow dots. From Bolivia and Peru.

S. bega Westw. Similar to the preceding species, but the wings are shorter, the form consequently more compact. Above dark brown. Beneath the forewing is lighter, unicolorous brown, only the apex is irradiated with black and white. Hindwing marbled with light and dark brown, sprinkled with silvery white dots and spots. From Venezuela, Colombia and Bolivia. — **andensis** Fldr. (51 g) is a form of *bega* in which the short silvery stripes on the underside of the hindwing form at the costa the letter V. From Bogotá (Colombia). — **modesta** form. nov. (51 g) is a somewhat smaller form, with the silvery white dots and markings on the underside of the hindwing almost entirely absent. Only a silvery dot in cellule 2 and a small silvery angled mark in cellule 3 persist. The tooth at the costal margin of the hindwing is as in the other forms. From Yungas de la Paz, 1000 m. (Bolivia).

S. zibia Btlr. Above brown with dark margin, distal area of the hindwing reddish, dusted with white at the anal angle. Beneath the forewing is lighter, with a yellow streak before the apex, the costa marbled with yellow and brown. Hindwing black, marbled with brown and rust-colour, the apical area ochreous with 2 rust-coloured spots, a silver spot before the apex and the spots at the costa as in *bega*, two black spots with silvery margins before the distal margin. Expanse 42 mm. From Venezuela.

34. Genus: **Pseudosteroma** gen. nov.

This new genus forms a transition between *Steroma* and *Steremnia*. As in the latter it lacks the broad, obtuse tooth which *Steroma* has at $\frac{2}{3}$ of the costal margin on the hindwing, but the other teeth, at the distal margin, project quite as far as in the latter genus. The first tooth is somewhat stronger than the rest and forms almost a right angle at the apex. The inner margin of the hindwing is quite as strongly excised as in *Steroma* and the distal margin of the forewing forms the same obtuse angle below the apex. The scent-scale spot is likewise mostly present.

P. pronophila Fldr. (*Steroma* p.) (51 g). Above brown, the distal margin and the scent-scale spot beyond the median of the forewing darker; the tips of the fringes between the veins whitish. Beneath the forewing yellowish brown, apex of the forewing and the whole hindwing marbled with dark brown. The latter with a white spot at the costal margin, a row of 6 white dots before the distal margin and a light brown spot at the anal angle. The ♀ is marked like the ♂ except that the scent-scale spot is absent. Colombia (Bogotá), 2800 m., Cipaque in the eastern Cordillera, 3000 m., found by FASSL at the Quindiu Pass at an altitude of 3800 m. — **umbracina** Btlr. is a form of *pronophila*, above olive-brown, apical third of the forewing somewhat lighter, the fringes alternately black and yellow-brown. Beneath almost as above, hindwing grey-brown at the apex, with an undulate, interrupted, dark brown submarginal line. Expanse 40 mm. From Peru.

P. monachella spec. nov. (*Thieme i. l.*) (52 a). Above dark brown, in the middle darker, at the distal margin lighter. Fringes dark brown, chequered with white. Beneath the basal half of the forewing reddish brown, distally lighter. Distal border $1\frac{1}{2}$ mm. in breadth, finely striated with dark brown and before the apex

powdered with white. Hindwing dark olive-brown, marbled and spotted with black, distal area lighter with a strongly dentate olive-brown submarginal band, a row of white dots before it, and some whitish yellow spots and streaks at the costal margin and anal angle. The distal margin is entirely dark brown. From Huancabamba, North Peru, at 3000 m.

agraulis. **P. agraulis** *spec. nov.* (51 f). ♂: above reddish brown, somewhat glossy, at the base somewhat darker. Forewing with 3 white dots before the distal margin in cellules 3, 4 and 5. Fringes white, spotted with black on the veins. Hindwing with 4 white dots in cellules 2 to 5. Marginal lines dark brown, fringes unicolorous brown. Forewing beneath brown, apex and distal margin white, irrorated with dark brown. The white dots of the upper surface are likewise present. Hindwing beneath dark grey, marbled with white and black, at the costal margin 2 broken white spots, at the inner margin 2 triangular grey spots, before the distal margin a row of white dots in black rings. Fringes brown. Differing from *monachella* in the absence of the dark brown scale-spot in the middle of the forewing above, the different shape of the markings on the hindwing beneath and especially in the absence of the dark black-grey border. Moreover the incisions in the distal margin are deeper and the teeth more pointed. From Bolivia.

35. Genus: **Steremnia** *Thieme*.

This genus lacks not only the teeth beyond the middle of the costal margin of the hindwing which *Steroma* possesses, but also the one placed at the apex itself, which projects rectangularly in *Pseudosteroma*. Hence the somewhat convex costal margin of the hindwing passes into the distal margin in almost an even curve. The excision of the inner margin is not so deep and the teeth of the distal margin project less than in the two preceding genera.

polyxo. **S. polyxo** *Godm. & Salv.* Above brown, in the ♂ unicolorous, in the ♀ with an obscure reddish brown submarginal band on both wings. Beneath the forewing brown, with yellowish brown apex. Hindwing yellowish brown, striated with dark brown, with a yellowish band before the middle, which is anteriorly widened and cleft into two. Before the distal margin a broad yellowish band, which in the posterior half of the wing projects widely proximad in 2 teeth, forming the letter W. Collected in the Sierra Nevada of Santa Marta (Colombia) by SIMONS and TETENS.

rugilas. **S. rugilas** *Thieme* (52 a). Above brown; on the forewing somewhat reddish before the middle of the distal margin. Forewing beneath reddish brown with grey apex, hindwing black-brown marbled with light, with indistinct white median band, arising from a white costal spot, and a row of white dots before the somewhat lighter distal margin. Colombia, Callegos on the Quindiu Pass at an elevation of 3000 m. (FASSL).

misella. **S. misella** *Thieme* (52 a). Above olive-brown, towards the margin somewhat lighter, the ♂ with scale-spot. Fringes of both wings chequered with brown and white. Beneath dark brown, at the distal margin of the hindwing and the apex of the forewing somewhat lighter and finely striated with dark, with an indistinct submarginal line. The teeth of the hindwing project but little. From Huancabamba in North Peru.

36. Genus: **Gyrocheilus** *Bltr.*

Costa of the forewing strongly curved, distal margin but little undulate, that of the hindwing dentate, inner margin of the hindwing rather strongly excised. The costal vein of the forewing is rather strongly swollen. Of the subcostal veins of the forewing the first arises before the end of the cell, the 2nd just at its anterior angle, the rest behind it. The middle discocellular vein on both wings is angularly bent inwards, consequently the posterior part of the cell is longer than the anterior. Medium-sized, dark brown butterflies, inhabiting Mexico and the neighbouring state of Arizona.

patrobas. **G. patrobas** *Hew.* (52 b). Above dark brown, forewing with 4 white dots in a row, fringes chequered with black and white. Hindwing with a broad red-brown submarginal band, on the proximal edge of which stand 2 white dots in cellules 2 and 3, and with a narrow, somewhat obscure red-brown stripe between this band and the distal margin. Beneath the wings are even darker brown than above. On the forewing the apex is powdered with white and the white dots are placed in black rings. On the hindwing the distal margin is broadly bluish grey, marbled with red-yellow and brown, at its proximal side is placed a row of whitish yellow spots, at its distal side several brown lines separated by red-yellow ones. In the highlands of Mexico (*tritonia.* Oaxaca, North Sonora, Durangocity, Jalapa). — The form **tritonia** *Edw.* only differs in its darker upper surface, the infuscated red-brown band of the hindwing and the absence of the white dots in this band. On the forewing above and beneath there are sometimes only 3 white dots instead of 4. From Arizona and North Mexico.

37. Genus: **Elina** *Blanch.*

In this genus 2 subcostal veins arise before the end of the cell on the forewing, the rest beyond it. The costal and median of this wing are inflated at the base. The distal margin of the forewing is undulate, that of the hindwing strongly dentate and its inner margin excised. The genus consists of medium-sized and small butterflies, and occurs in Chile and the adjoining and neighbouring countries.

E. lefebvrei *Guér.* (= *montrolii* *Feisth.*) (52 b). Above brown with a red-brown submarginal band which is strongly constricted in places and on the forewing interrupted by the brown veins. Before the apex of the forewing are placed on this band some ochreous longitudinal rays and 2 dark brown spots. There are sometimes also a small brown spot in cellule 2 and a brown spot in the same cellule of the hindwing. The basal and median areas are strongly dusted with red-brown. On the under surface the forewing is rust-brown to the submarginal band, the band ochre-yellow, anteriorly white, the 3 dark spots black with white pupils. The distal margin is brown. Across the middle of the hindwing runs a dentate dark brown band, basally blurred, distally as a rule sharply defined. Then follows a grey-white submarginal band sprinkled with brown and then the dark brown distal margin. The ♀ is considerably larger, having an expanse of 70 mm. The basal half of both wings is almost entirely red-brown, the anterior dark spot has a white centre and the under surface is lighter than in the ♂. — The larva is light brown with black longitudinal lines. Head large, with 2 black lines and a light spiracular line, bordered with black beneath; the dorsum is somewhat darker brown, the anal extremity with 2 points. It is full-grown in October and lives on "Coligne" (*Chusquea* sp.?). The pupa is light brown with some black streaks and spots. The butterfly appears in November and December and is locally common in Chile, but more in the plains than in the mountains. It occurs also in Argentina and Uruguay. *lefebvrei*.

E. vanessoides *Blanch.* (52 b). Similar to the preceding species, but somewhat smaller. The hindwing is elongate and less dentate. The band is lighter and the dark brown spots in cellule 2 are absent on both wings above and on the forewing beneath. The dark brown spots before the apex of the forewing have no white pupils on either surface. Hindwing marbled with light and dark brown, crossed by a curved white stripe, interrupted on vein 5. Beyond this a submarginal band, which is somewhat lighter than the ground-colour and bears in cellule 2 a dark brown spot with red-yellow ring. From Valdivia in Chile, where it is not rare. *vanessoides*.

E. calvertii *Elw.* A small species with the distal margin of the forewing straight. The ♂ above dark brown, with 2 small, obscure red-brown submarginal spots in cellules 2 and 3 on both wings. Beneath the forewing is brown, at the base dark red-yellow to the middle, with a broad, straight red-yellow submarginal band, in which is placed before the apex a round black spot with ochre-yellow ring. The hindwing is marbled with light and dark brown, with a large white spot at the apex, strongly sprinkled with brown; a row of white dots is placed before the distal margin. The ♀ shows an increase in the number of the red-brown spots on the upper surface, on the forewing brown dots are placed in these spots and the eye-spot of the under surface shows through above. On the underside of the hindwing the white spot at the apex forms the beginning of an ochre-yellow band, irrorated with brown, which is continued to the inner margin. The distal margin of the hindwing is only slightly undulate in the ♀. The ♂ has on the upperside of the hindwing a spot of velvety scales. Not rare in a wood below the Baños of Chillan in Chile, in December. Also found at Lake Quillen in Argentina (ELWES). *calvertii*.

E. nemyrioides *Blanch.* (= *nemyroides* *Reed*, *neomyrioides* *Elw.*) (52 b). The distal margin of the forewing before the apex produced into an obtuse angle, in the ♂ somewhat more than in the ♀. Otherwise very similar to the preceding species; the ♂ has the same spot of velvety dark brown scales in the middle of the forewing. Beyond this spot the ground-colour is strongly mixed with red-brown. The under surface, which is here figured, is very similarly marked to that of *calvertii*, but the white spot at the costal margin of the hindwing is purer white in *nemyrioides* and is continued as a dentate white line to the inner angle. In the ♂ the red-brown band on the underside of the forewing occurs also on the upperside in the same breadth and encloses here likewise a round black apical spot. The hindwing in the ♀ has on the upper surface a submarginal row of small red-yellow spots and on the under surface the white spot at the costal margin is much larger. From Chile, at the Baths of Chillan and in Valdivia (according to EDMONDS), at San Ignacio and Port Blest (according to ELWES). Not common in the Central Provinces, but less rare in Valdivia (REED). Flies January to March. *nemyrioides*.

38. Genus: **Eteona** *Westw.*

The shape of the wings is about the same as in *Elina*, the distal margin of the forewing is undulate and has below the apex an obtuse angle, that of the hindwing is dentate, but the inner margin of the latter is not excised. Only the costal of the forewing is inflated, the other veins are normal. In the ♀ 2 of the subcostal veins of the forewing arise before the end of the cell, the rest behind it; in the ♂ on the other hand only one before the end of the cell, whilst the 2nd arises exactly at the angle. The butterflies inhabit South Brazil.

E. tisiphone *Bdv.* (*Euterpe* t.) (52 a). Above dark brown with a row of yellowish white spots across both wings, covering the greater part of the hindwing, but on the forewing mostly obsolescent in the ♂. Single ♂♂ have the forewing above entirely black-brown. On the under surface the ground-colour is lighter, the veins black, and between them are placed black longitudinal rays and short white longitudinal streaks. The macular band is pure white and in the ♂ also extends to the costal margin of the forewing. The spots are individually smaller, but their number is larger in both sexes than above. The butterfly is distributed in South Brazil *tisiphone*.

from Rio de Janeiro to Rio Grande do Sul, but also occurs (according to STAUDINGER) in Colombia. BOISDUVAL in his „Species Général“ gave Chile as locality. BUTLER and ELWES, however, do not mention the species in their lists of the Chilean butterflies, and REED expressly says in his „Mariposas Chilenas“ that it is not Chilean.

vulpecula. **vulpecula** Weym. (52 a) is a female form of *tisiphone* in which the macular band on the upperside is not yellowish white but ferruginous red-brown. The cell of the forewing is also reddish brown. Only some small spots before the apex of the forewing remain light yellow. The under surface is entirely brownish ochreous, which colour has absorbed all the white spots and rays, only the black veins, spots and longitudinal rays between the veins being still present. From Rio Grande do Sul.

eupolis. **E. eupolis** Hew. (52 a, b). Forewing above brown with red-yellow longitudinal stripes at the base, a sulphur-yellow band beyond the middle and a spot of the same colour before the apex. Hindwing red-yellow with broad brown distal margin. Beneath as above, but lighter, the apex of the forewing with black longitudinal lines, the hindwing with white, black-edged longitudinal rays between the veins in the marginal area.

flava. From Rio de Janeiro and Esperito Santo. — As **flava** *form. nov.* I introduce a form of *eupolis* in which the red-yellow colour of the forewing above and beneath is replaced by sulphur-yellow and the greater part of the hindwing is lemon-yellow; of the red-yellow colour of *eupolis* only a stripe about 4 mm. in breadth beside the brown distal margin remains. Beneath the lemon-yellow ground-colour of the hindwing extends nearly to the termen, the brown border being absent, but the black lines and veins, as well as the white, black-edged longitudinal rays, are as in *eupolis*. From Esperito Santo.

39. Genus: **Zabirnia** Hew.

Size and shape of *Catagramma*. Head small. Eyes naked. Palpus long and thin, twice as long as the head, covered with long hairs. Antenna less than half the length of the forewing, with long club. Forewing: costal and distal margins convex. Inner margin straight. Costal strongly swollen at the base and reaching to the middle of the costal margin. Two subcostal veins arise before the end of the cell, which is somewhat more than half the length of the wing. The upper discocellular is short, the middle forms an angle inwards. The distal margin of the hindwing is semicircular, the cell less than half the length of the wing.

zigomala. **Z. zigomala** Hew. Above dark brown. Basal half of the forewing reddish orange with the veins black. Beneath as above, but lighter brown, the distal half of the forewing and the whole of the hindwing, with all the veins and the lines between them black, on the forewing 2 ochre-yellow spots at the costal margin beyond the middle and a round black spot between the 1st and 2nd median vein. The hindwing has beyond the middle an indistinct band, somewhat lighter than the ground-colour, running parallel with the distal margin. 54 mm. From Jima in Ecuador. Coll. HEWITSON (Brit. Mus.).

40. Genus: **Sabatoga** Stgr.

Apex of the forewing produced, not pointed but rounded, the inner angle on the contrary strongly rounded off, the costal margin nearly straight, hence the forewing is comparatively narrow. Only one subcostal vein arises before the end of the cell, subcostal vein 4 runs into the costal margin immediately before the apex. Hindwing with an obtuse angle in the middle of the distal margin. The rest of the venation of this wing is as in *Idioneura*; the cell is distally as strongly rounded as in that genus. Palpus long, with long hairs. Antenna thin with the club strongly thickened. Eyes naked.

mirabilis. **S. mirabilis** Stgr. ♂: forewing brown-black with a large, transparent white inner-marginal spot and a small elongate subapical one. Hindwing whitish, inner margin, base and costal margin densely dusted with dark brown-grey; only the apical half is pure white, with a row of black spots (which, however, may also be absent). Beneath the forewing is dirty white, with the apical area red-brown or dull yellow-brown. Hindwing brown, towards the inner margin grey, on the median vein, the three median branches and the lower radial are placed silvery stripes, some of which are bordered with brown. 5 black dots between the veins. Only 2 examples of the species are known, in coll. STAUDINGER (now in the Zool. Museum in Berlin). They came from the THALENHORST collection at Hamburg and bear the locality-label: Sabatoga in Colombia.

41. Genus: **Lymanopoda** Westw.

Palpus long, with long, stiff, erect hairs, only the dorsal surface and the terminal joint short-haired. Antenna with the club gradually thickened. A special distinguishing mark of the genus is that the forelegs of the male are very much aborted. Eyes slightly hairy. In the forewing the costal is inflated at the base, the median only slightly thickened, the submedian not at all. Two subcostal veins arise before the end of the cell and the 4th subcostal runs into the costal margin before the apex. The upper discocellular is short, the middle and lower vary in the different species. Sometimes the middle, sometimes the lower, forms a proximally directed angle, from which arises a small vein running into the cell. Occasionally, however, this veinlet

is placed at the point where the two veins meet, thus forming a continuation of the lower radial. The hindwing of several species shows a similar recurrent veinlet, its position varying as in the forewing. — The genus is composed of small or quite moderate-sized butterflies, mostly with rounded wings. Only the apex of the forewing is in several species almost squared, in single cases even pointed. Others have an obtuse angle in the middle of the distal margin of the hindwing, while in others again it is placed at the anal angle of the hindwing. The upper surface is mostly unicolorous brown, only a few species having the ground-colour white or glossy blue. Frequently white dots are placed in a curved row on both wings, occasionally these are replaced by eye-spots. Single species have silvery spots or bands on the underside of the hindwing. The head-quarters of this genus are the Andes of tropical western America, where it is distributed from Costa Rica to Peru.

Upper surface white.

L. lactea *Hew.* White, base dusted with darker; forewing: costal and distal margins reddish, a black *lactea* submarginal stripe, also a spot in the middle of the costal margin, a large quadrate spot at the apex and a small, round, white-centred spot between the 2nd and 3rd median veins, all black. On the hindwing the veins are black towards the distal margin; 2 black dots in cellules 4 and 5 and one in cellule 1 c. Beneath white, the margins of the forewing and the whole of the hindwing light yellow. The spots on the forewing are in part indistinct. The hindwing is traversed by 2 oblique red-brown bands, on the lower of these bands are placed 3 black dots, a black dot at the apex and 3 further dots in the posterior half of the wing. Expanse 40 mm. From Colombia.

L. galactea *Stgr.* (52 c). Slightly glossy white. Forewing with the costal margin narrowly black and *galactea* with a broad black distal border, decreasing but little in breadth posteriorly and reaching to the first median vein. In this are placed several white dots. Hindwing with black spot in the anterior part of the distal margin. On the under surface the terminal band is shorter and its distal half is brownish. The white dots are here bordered with black. The underside of the hindwing is crossed by 3 brown transverse stripes which show through slightly above. From Cillutincara (province of Yungas, Bolivia). Collected by GARLEPP.

L. eubagioides *Bthr.* Similar to the preceding. White, at the base blackish green, costa, apex and *eubagioides* distal margin of the forewing narrowly ferruginous, the space before the apex from the costa to the first median vein black. The distal half of the cell and 2 spots in cellules 2 and 3 are also black. In the black apical area are placed a semicircular spot at the end of the cell, an oblique band midway between cell and apex and 4 small dots before the apex, all white. Beneath white, the forewing with red-brown disc, spotted with white; costa, apex and distal margin pale ochre-yellow. Two dark spots in cellules 2 and 3, the upper with white centre and ochre-yellow ring. Hindwing dirty white, dusted with brown, with a number of oblique brown streaks in the basal area and 7 black dots in the distal area. 43 mm. From Peru.

L. nivea *Stgr.* (52 c). Forewing white, with black costal and distal margins, the former narrow, the latter *nivea* anteriorly broad, posteriorly narrow; four white dots in a curved row before the apex, a black spot on the discocellular. Hindwing white, only the base dusted with grey. Beneath the costal margin and apex of the forewing are dusted with yellowish grey. From Ecuador (Quito). — **melia** *form. nov.* (52 c) is a form of *nivea* *melia*, in which the black spot on the discocellular of the forewing is joined to the black distal margin, so that the distal half of the forewing is black to the middle of the costal margin and to the inner angle, and only interrupted by one larger and 2 or 3 small white spots. The hindwing is dusted with darker at the base. On the underside of the forewing before the apex are placed 3 brown dots in the positions where *nivea* has white ones and a 4th brown dot in cellule 3. In the ♀ the apex of the forewing and the whole hindwing are dusted with yellowish grey beneath. Collected by FASSL at the Quindiu Pass in Colombia at 3800 m. in September to November. — **sororecula** *Thieme* is a further form of *nivea*; markings on the upper surface not black but bright *sororecula* rust-brown, only the spot at the end of the cell and the distal margin somewhat darkened, the narrow border at the costal margin rust-yellow. From Ecuador, environs of Chimborazo (HAENSCH).

L. huilana *Weym.* (52 c). The white ground-colour of the upper surface is much darkened in the basal *huilana* half of the forewing by dark brown dusting. The apical half is black-brown extending into the cell and to the inner angle and proximally forming several projecting angles. In it is placed in cellules 4—6 a dull white macular band. In the middle of cellule 2 there is a dark brown spot on white ground. The hindwing is almost entirely covered with brown dusting, so that only in the middle somewhat of the white ground-colour remains. The basal area has white hairs. A row of brown dots before the margin. On the under surface the costal margin, apex and distal margin of the forewing are brownish ochre with the same row of dots as above. Collected by STÜBEL on the Paramo des Huila in Colombia at 4000 m. — **tolima** *form. nov.* (52 c) is a form of *huilana* *tolima*, in which the forewing is less dark-dusted, so that there is a large white area in the middle, extending from the anterior margin of the cell to the anal angle. The round dark brown spot in cellule 2 is as in *huilana*. The dark dusting of the entire hindwing is on the contrary so strong as to produce a bluish grey colouring,

only interrupted by a white longitudinal ray. The underside of the forewing is as in *huilana*, that of the hindwing is light brownish yellow with the same white longitudinal ray as on the upper surface but here posteriorly bordered with dark brown. The row of dots as above. On the Paramo des Tolima in Colombia, 4200 m., found in January by FASSL.

palumba.

L. palumba *Thieme*. Somewhat smaller than the preceding forms. Forewing white with black-brown apex, costal and distal bordering. The dark costal border embraces the whole cell, extends broadly to the apex and then at the distal margin obliquely recedes nearly to the inner angle without proximal teeth. At the base this margin is glossy slate-green, before the apex ferruginous, otherwise black-brown. A white spot at the end of the cell, a somewhat larger one above it and 3 or 4 white dots before the apex. Hindwing entirely white, at the base with slate-green reflection. The under surface is whitish yellow, clouded with rust-brown dusting, and with a rust-brown spot in the cell of the forewing. From Bolivia (province of Yungas de la Paz).

Upper surface blue.

samius.

L. samius *Dbl.* (52 c). The most beautiful species of the genus. Above glossy blue with black-brown distal margin, which gradually decreases in breadth from the costal margin of the forewing to the inner angle of the hindwing and on the forewing encloses glossy blue spots and white dots. The hindwing is bordered with a row of black dots. Under surface bright ochre-yellow, on the forewing with 3 or 4 small black, white-pupilled eye-spots and some white dots before the apex, corresponding in position with the white dots of the upper surface. On the hindwing are placed a curved row of black dots and a dentate brown submarginal line. Two brownish transverse stripes run from the basal half of the inner margin to the apex. The ♀ is lighter and less glossy blue above. The inner margin of the hindwing is dusted with brownish grey as far as the median. Sometimes the blue colour is changed into a delicate red. According to FASSL the egg is nearly as large as that of *Pap. machaon*, but pear-shaped, broader above than beneath, somewhat constricted in the middle, reddish grey, with a silky gloss, and with narrow longitudinal ribs, terminating above in a dark elevation. The larva is still unknown; the foodplant is probably the wild mountain sugar-cane (*Chusque*), near which FASSL mostly took the butterflies. Bogotá (Colombia) on the mountains bordering the plateau, at altitudes of 2800 to 3200 m. On account of its rapid flight the butterfly is difficult to catch.

caeruleata.

L. caeruleata *Godm. & Salv.* Above similar to the preceding species, but beneath quite different. The black distal margin of the glossy blue upper surface is somewhat broader, the blue spots in it are absent, only the white dots being present above. On the underside the forewing is brown at the base, the central area broadly black with blue spots and white dots, the apex and distal margin light ochre-yellow. The hindwing is entirely ochre-yellow, at the base dusted with brownish, with 2 brownish transverse stripes in the basal half, a brown, dentate submarginal line and a row of 7 dark brown dots. From the Sierra Nevada, Santa Marta, Colombia (SIMONS).

Upper surface brown.

cinna.

L. cinna *Godm. & Salv.* Above brown, forewing with a curved row of 6 white dots. Hindwing with the base blue, this colour extending along the inner margin to the anal angle. Beneath the forewing is reddish brown, at the distal margin lighter. The white dots are as above, but all placed in black rings, and on the discocellular there is a light, black-margined patch. The hindwing is somewhat lighter reddish brown and bears beyond the middle an obscure row of round brown spots with white central dots. Before and behind this row of spots a dentate brown transverse line. From Guatemala, San Lucas Toliman near the Lake of Atitlan, taken by CHAMPION at an elevation of 5000 ft. Only one example, in coll. GODMAN and SALVIN.

marianna.

L. marianna *Stgr.* (52 d). Above black-brown. Forewing with 3 white dots before the apex, hindwing with large golden green inner-marginal spot. Beneath the forewing is chestnut-brown, with the apex brownish yellow, and before it 3 white dots, 2 black, white-pupilled eye-spots between the median veins. Hindwing beneath brownish yellow with 2 brown and 2 white-grey transverse bands, as well as 4 or 5 black dots with white centres. From the mountains of Merida (Venezuela).

labda.

L. labda *Hew.* (52 d). ♂: above unicolorous dark brown. Beneath reddish brown. Forewing with 5 silver-white dots in an interrupted row before the distal margin, the last 2 in black rings. Hindwing with 2 transverse rows of silvery spots and with several small silvery spots and dots between them and at the anal angle. The ♀ was discovered by FASSL and is very different from the ♂. It has on the upperside of the forewing 5 white dots, 3 before the apex near the distal margin and 2 further removed from the margin between the median veins. The hindwing is unicolorous brown. Beneath the forewing is yellowish brown to two-thirds of its length, the distal margin ochre-yellow. Instead of 2 eye-spots there are here 3 before the inner angle. The white dots before the apex are larger than in the ♂. The hindwing has no trace of silvery spots. It is yellowish white-grey, with the base dusted with light brownish yellow and with 2 transverse stripes of the same colour,

one placed just behind the cell, the other before the distal margin. Localities: Colombia and Ecuador. The ♀ was found by FASSL on the Quindiu Pass at Machiu at 2500 m.

L. lebbaea Fldr. (52 d) is somewhat similar to the preceding species, but the forewing is more pointed *lebbaea*, with the distal margin nearly straight. On the under surface the hindwing and the apex of the forewing are not red-brown but brownish ochre. The silvery spots on the hindwing are much reduced in number. Of the first silvery transverse band only the large spot at the end of the cell is present. The 4 spots of the 2nd transverse band are smaller, the last spot in particular indistinct. Several of the other silver dots are also absent. From Bogotá (Colombia). The figure is from FELDER's type in the Tring Museum.

L. ferruginosa Btlr. Similar to *labda*, but with the apex of the forewing more rounded and the inner *ferruginosa*, margin shorter. The distal margin of the hindwing is somewhat prominent in the middle. Above brown, forewing with a white dot before the apex and another in the disc. On the under surface of the hindwing all the larger discal spots are not silvery, as in *labda*, but orange, only the spot before the discocellular is yellowish silvery. From Bolivia. — **translucida** Stgr. i. l. is a form of *ferruginosa* in which the reddish yellow macular *translucida*, bands of the under surface of the hindwing show through weakly on the upperside also. On the upperside of the forewing is placed before the apex a short, indistinct red-yellow band, and beside it proximally 1, distally 3 white dots. Beneath the distal half of the forewing is bright ochre-yellow with 2 black, white-pupilled eye-spots between the median veins. From Bolivia. — **hyagnis** form. nov. (52 d) is a form with 3 or 4 white dots *hyagnis*, before the apex and in the marginal area on the dark brown upper surface of the forewing. Beneath the basal half of the forewing is light brown, the distal part ochre-yellow, with 2 dark brown, white-pupilled eye-spots and 2 brown spots beyond them between the median veins and with several white spots and dots before the apex. The hindwing is light ochre-yellow, finely dusted with brown, with several brown spots and broken transverse bands. At the posterior end of the cell is placed the silvery spot which is common to all forms of *ferruginosa*. Bolivia. — **rana** form. nov. (*Thieme i. l.*) (52 d). Likewise a form of *ferruginosa*, with the underside *rana*, of the forewing reddish brown and characterized by a broad dark brown submarginal band, in which 2 white dots are placed between the median veins. A white patch stands before the apex and beside it 3 white dots near the distal margin. The hindwing has the ground-colour likewise red-brown and 3 dark red-brown transverse stripes between the middle and the distal margin. Five white dots in a curved row and the silver spot at the end of the cell stand out distinctly. From Huancabamba in North Peru.

L. jonius Westw. (52 e). The apex of the forewing forms a right angle. Above brown with 4 white dots *jonius*, in cellules 3—6, the middle 2 placed nearest to the distal margin. Fringes grey. Beneath the base and the costal and distal margins of the forewing are brownish ochre, the middle red-brown, distally darker, with 5 white dots. The underside of the hindwing is brownish red-yellow with 3 oblique, dentate brown lines and a row of black dots. The ♀ is more reddish brown above, the hindwing finely margined with reddish yellow at the inner margin. The forewing has 5 white dots on both surfaces. On the under surface the apex of the forewing and the whole hindwing are light yellowish grey. Instead of the dentate lines of the ♂ there are in the ♀ obscure bands formed of brownish dusting. From Chipaque in the Colombian East Cordillera (3000 m.), where also the ♀ was found by FASSL. Flies in April.

L. excisa spec. nov. (52 f). The distal margin of the forewing is slightly excised below the apex, hence *excisa*, the apex is prominent, especially in the ♀. Above brown, forewing with 5 white dots, placed in a very sinuous row. Hindwing without markings. Beneath the forewing is red-brown; before the distal margin a black-brown band, on which are placed 5 or 6 white dots. Hindwing olive-brown with 3 dark brown, almost horizontal stripes and a row of black dots between the 2nd and 3rd. ♀ considerably larger, with the distal margin of the forewing rounded in the middle. The ground-colour of the forewing is reddish brown above, the dots as in the ♂. The hindwing has the inner margin ferruginous brown for a breadth of $1\frac{1}{2}$ mm. The fringes are grey-brown. Beneath the forewing is light red-brown with dark brown spots and bands. The white dots as in the ♂. The hindwing unicolorous yellow-brown with a narrow, oblique brown stripe across the middle. Colombia (Quindiu-Pass, 3500—3800 m., Monte Socorro, 3600 m.). Discovered by FASSL. Flies in July and September.

L. obsoleta Westw. (= *larunda* Hopff.) (52 e). The hindwing is obtusely angled in the middle of the distal *obsoleta*, margin. Above brown with 2 white dots, one above the other, before the apex of the forewing. Beneath likewise brown with the same 2 white dots and below them 2 black eye-spots with white pupils, the first placed proximally. Hindwing reddish brown, with 2 lilac transverse bands, partly interrupted by rust-red colour, finely dusted with brown all over, with a strongly curved row of 5 to 7 white dots, often bordered with black. The ♀ of this species occurs in 2 forms, which differ not only in the markings but also in shape, one agreeing with the ♂, while the other approaches *gortyna*. The first form (52 e) has the distal margin of the forewing more strongly rounded, but the hindwing has the same obtuse angle as the ♂. On the upperside of the forewing are placed four white dots, two in cellules 4 and 5 near the distal margin and two in cellules 2 and 3 more proximally. The first dot is somewhat larger and transparent. On the under surface of the forewing the 2 eye-spots are as in the ♂, but broadly margined with red-yellow, and the light bands of the hindwing are broader and reddish grey-brown. This form was taken by FASSL at the Quindiu Pass, 2500 m., in West Colombia in Sep-

gortynoides. tember. The other form of the ♀, which I call **gortynoides** *form. nov.*, has been already briefly mentioned by THIEME in the Berliner Entom. Zeitschr., vol. 50, p. 70. It resembles *Lym. gortyna*, but is smaller (expanse 50 mm.), the hindwing not round but bent or obtusely angled at the distal margin and the row of eye-spots on the hindwing not present beneath. THIEME possessed this form from Bogotá, Merida and Bolivia. FASSL has now also met with it flying together with ♂♂ of *obsoleta-larunda* in the Colombian East Cordillera. These ♀♀ have the same strongly undulate hindwing that THIEME mentions, but the eye-spots on the underside of the hindwing are not absent but are present in cellules 1c to 5 (in cellule 1c there are two), and although some of them are small those in cellules 2 and 3 are distinct, and all have white pupils. The upper surface is dark brown. Forewing with 2 large ocelli between the median veins, bordered with red-yellow and with white pupils; sometimes also a somewhat smaller, blind eye-spot below them in the inner angle. Two very small, indistinct ocelli before the apex. On the hindwing are placed 5 round black spots in red-yellow rings, in a curved row, only the last of which has a white pupil. The ground-colour of the under surface is yellowish grey-brown, finely striated with dark brown, towards the base darker. Forewing with the same markings as the upper surface, but with the bordering of the eye-spots lighter. Hindwing variable as regards the eye-spots, as already mentioned above. *obsoleta (larunda)* occurs in Colombia, Venezuela, Peru and Bolivia. — My grounds for employing the name *obsoleta* for this species which is known in Germany under the name *larunda* are as follows: HOPFFER says at the conclusion of his description (Stettin. Ent. Zeit. 1874, p. 361): "Differs from all the species known to me in the distinctly angled hindwing." Thus he has overlooked the fact that the figure of the upper surface of *obsoleta* in the „Genera Diurnal Lepidoptera“ shows just these angles and also agrees with *larunda* in the shape of the forewing, as well as the colouring and markings. Unfortunately the author of the above work gives neither a description nor a figure of the under surface. But I am indebted to Mr. KIRBY of London for a description of the underside of *obsoleta* drawn up from the type in the Brit. Museum and fully agreeing with *larunda* ♂.

gortyna. **L. gortyna** Weym. (53 a). Of this species only the ♀ is known; it is similar to the 2nd form of the ♀ of *obsoleta (larunda)* and to that of *albocincta*. It is, however, larger than either. Ground-colour of the upper surface brown, distally lighter. On the forewing there are 5 eye-spots, of which the 3rd and 4th are placed more proximally and are much larger than the rest. The hindwing has a proximally curved row of 5 small, white-pupilled eye-spots. On the under surface the wing is finely striated with dark brown to the base, the eye-spots on both wings are as above, except that the 2 larger on the forewing are bordered with ochre-yellow and the smaller, at the anal angle, is absent. The hindwing has a somewhat lighter submarginal band. From Paramo de Guasco (2500 m.), Colombia (STÜBEL).

levana. **L. levana** Godm. (51 b). Forewing with the apex pointed, but not sharply, distal margin nearly straight. Upper surface dark brown, both wings with a small black, white-pupilled eye-spot in cellule 2 and one or two black dots above it. Forewing beneath as above, but the distal margin ferruginous, anteriorly broad, posteriorly narrow. Hindwing likewise ferruginous, with a strongly dentate ochre-yellow band. Chapmero near Bogotá, 2800 m. (FASSL). Flies in September.

apiculata. **L. apiculata** Fldr. (53 a, misprinted *apiciculata*). Shape of the preceding species, but the apex of the forewing somewhat sharper and the distal margin slightly excised below the apex. Above dark brown, distally somewhat lighter, without markings. Beneath likewise dark brown; forewing with a fine, dentate dark brown submarginal line, which is followed by grey dusting to the distal margin, proximally broadly dusted with yellowish. Beside this a row of white dots. Hindwing with broad grey-brown distal margin, also with a row of white dots at its proximal side and traversed by a dark brown dentate submarginal line. In the middle of the hindwing a row of yellowish brown spots. Colombia (Bogotá [LINDIG], Boqueron de Cipaque in the Colombian East Cordillera, 3200 m.). Flies in January (FASSL). — **curvilinea** *form. nov.* is a form of *apiculata* which has on the underside of the hindwing a somewhat outcurved white line instead of the row of yellowish brown spots. This line traverses the whole wing from $\frac{2}{3}$ of the costal to $\frac{2}{3}$ of the inner margin. Boqueron de Cipaque, 3200 m., Colombian East Cordillera (FASSL).

altis. **L. altis** Weym. (52 f). The apex of the forewing is rectangular; the hindwing rather obtusely angled at vein 4 and its distal margin somewhat undulate. Above brown; the basal half of both wings somewhat lighter brown. Beneath lighter brown. The apex of the forewing occupied by a red-brown triangle, at the proximal edge of which are placed several white dots. Between the median veins 2 black, white-pupilled eye-spots in red-yellow bordering. Across the middle of the hindwing runs a straight white band, irregularly defined at the edges, from the costal to the inner margin, including the apex of the cell. Beyond this a row of white dots. Colombia (Paramo de Aponte, 2800 m.) (STÜBEL), Ecuador.

leaena. **L. leaena** Hew. (52 f). Above dark brown; distally reddish brown. Forewing beneath as above, but with a submarginal row of white dots. Hindwing beneath brown with a straight, light yellow band through the middle and a row of white dots beyond it. Distal margin dusted with grey. The ♀ differs from the ♂ only in having a small, triangular white spot on the upper surface at the apex of the hindwing, which marks the beginning of the light band of the under surface. Colombia, eastern slopes of the Cordillera of Bogotá, 2000—2500 m.,

Parano de Aponte, 2800 m. (STÜBEL), Quindiu Pass, 3800 m. (FASSL), Ecuador: Quito (STÜBEL). — **lanassa** *lanassa* Fldr. (52 f) is a form of *leaena* with somewhat broader wings, in which the white dots are absent on the underside of both wings and the light yellow band is narrower. Before the margin of the forewing there is a dentate brown line on the under surface. Bogotá. — **satura** *form. nov.* (52 f). Likewise a form of *leaena*, *satura*, on the under surface of which the posterior white dot of the forewing and also the first two and the last two dots on the hindwing are replaced by eye-spots. These are black with white pupils and yellow rings. Before the distal margin a dark brown dentate line. Sometimes the eye-spots are very small and indistinct. Cuzco, 2—3000 m. (Peru), Quindiu Pass, 2400 m. (Colombia, FASSL).

L. lisa *spec. nov.* (52 f). An easily recognized species. Above brown with a red-yellow band beyond *lisa*, the middle of the hindwing, which in the anterior half is narrow and indistinct, but in the posterior half gradually increases in breadth and at the inner angle extends along the distal margin. On the under surface the forewing is unicolorous dark brown; the hindwing likewise dark brown with a straight, light reddish yellow band, occupying the same position as above, anteriorly 1 mm., posteriorly 2 mm. in breadth, sharply defined at both sides and proximally bordered by a white line. Beyond this 2 fine white dots in cellules 2 and 3, and before the distal margin a brown undulate line. South-East Peru.

L. albocincta Hew. (52 c). ♂: above unicolorous brown. Beneath reddish brown, forewing with 1 or 2, *albocincta*, occasionally 3 white dots, which, however, may also be entirely absent. Hindwing finely striated with dark brown, with a fairly straight white band, which is interrupted by the brown veins. The very different ♀ (52 c) was discovered by FASSL. It is similar to *gortyna* and *gortynoides* and is distinguished by the large black eye-spots, with white pupils and red-yellow rings, on the upperside of the forewing between the median veins. In cellules 4 and 5, nearer to the distal margin are placed 2 small black rings with white centres. Hindwing without markings. Beneath the forewing is brown, costal and distal margins brownish grey, irrorated with dark brown, the large eye-spots as above; the small eye-spots replaced by white dots. Hindwing brownish grey, irrorated with dark brown, with lighter submarginal band. From the Rio Vitaco, 2500 m., West Cordilleras (Colombia).

L. albomaculata Hew. (52 g). Above brown. Beneath reddish brown, forewing with a straight row *albomaculata*, of white dots, hindwing with a curved row of 7 nearly round white spots. Sometimes some white dots are present also on the upperside of the forewing. Colombia, Rio Pongo in Bolivia. — **affineola** Stgr. i. l. (52 g) *affineola*, is a form of *albomaculata* in which the first three white spots on the underside of the hindwing are rather large, but the other 4 very small and punctiform, so that the row appears much more strongly curved. Sometimes the first and third spots are also very small. On the under surface of the forewing the two posterior white dots are placed in black rings and removed somewhat proximad. On the upper surface there are on the forewing 3 white dots, on the hindwing one. Cuzco in Peru, Bolivia. — **apulia** Hopff., a further form of *albomaculata*, *apulia*, differs in having the white macular band on the underside of the hindwing running straight across the disc like a string of pearls. The separate spots are round, of uniform size and placed rather close together. On the upperside of the forewing are 3 red-yellow submarginal spots and on the hindwing a red-yellow subapical spot. From Bolivia.

L. maso Godm. is aberrant in shape. The apex of the forewing is truncate, the distal margin consequently projecting in an obtuse angle, that of the hindwing is dentate and forms a right angle at the 3rd median vein. The upper surface is unicolorous brown. Beneath likewise brown, apex of the forewing and inner margin of the hindwing dusted with lilac. Forewing with an almost straight submarginal row of 6 white dots. Hindwing with an excurved row of 6 or 7 white spots, with yellow central dots. 48 mm. From Colombia (Frontino in Antioquia).

L. villarresi Dogn. has the distal margin of the forewing rounded. That of the hindwing is somewhat *villarresi*, undulate with the inner angle obtuse. The upper surface is unicolorous brown, the under surface likewise brown, at the distal margin lighter, with a short row of 2 or 3 white spots not far from the apex, near the costal margin. 48 mm. From Loja in Ecuador.

L. euopis Godm. & Salv. Distal margin of both wings rounded. ♂: above brown. Forewing with 5 *euopis*, black, white-pupilled eye-spots in a curved row before the distal margin. Hindwing in the middle with a row of 5 black, non-pupilled spots. Beneath ferruginous, the eye-spots of the forewing as above and placed in an ochre-yellow band bordered with dark brown. On the hindwing a row of small eye-spots is present instead of the spots. In the ♀ the eye-spots on the upperside of the forewing are placed in a broad, strongly curved ochre-yellow submarginal band. The distal half of the hindwing is entirely ochre-yellow, only a narrow distal and inner margin and the row of spots are brown. The under surface in the ♀ is light brownish ochre-yellow, darker towards the base; the markings of the forewing as in the ♂, the hindwing with only a row of brown dots. Found by ROGERS at the Volcan de Irazu and Cache in Costa Rica. Rare.

L. panacea Hew. (52 g). Above unicolorous brown. Beneath reddish brown, margin of the forewing *panacea*, and the whole hindwing with undulate dark brown markings. Forewing with 2 black, white-pupilled eye-

- spots and a white dot above them. Hindwing with a row of small black dots, some of which have white pupils. The ♀ is reddish brown above, distally paler, with 4 eye-spots which have light reddish rings and white pupils, the 2 placed before the apex being smaller. From Ecuador (Huamboya, Riobamba). — *venusia* Hopff. (52 g) is a form of *panacea* in which the white dots on the underside are silvery and more numerous. The black dots of the hindwing all have silver-white pupils. From Peru. — *marica* Stgr. (53 a), likewise a form of *panacea*, differs in the ♂ having on the upperside of the forewing 2 distinct black eye-spots between the median veins and sometimes single eye-spots also on the hindwing above. Cuzco (Peru). — *caucana* form. nov. (52 g), a further *panacea* form, has both above and beneath 3 white dots in an oblique row before the apex of the forewing. On the under surface the apex as far as these dots is bright light rust-brown, which colour is continued along the distal margin to the inner angle. The rest of the forewing is dark black-brown with 2 or 3 white dots in cellules 1 b, 2 and 3. The hindwing is dark rust-brown with a curved row of 4 or 5 obscure black dots with white pupils. Cauca Valley (Colombia).
- cillutinarca*. **L. cillutinarca** spec. nov. (Stgr. i. l.) (53 a). Above unicolorous reddish brown, distally somewhat lighter. Beneath the same, on each wing with a row of 4 or 5 white dots, running parallel with the distal margin, some of them placed in fine black rings. A fine dark brown dentate line near the distal margin on both wings. From the Mapiri (Bolivia).
- venosa*. **L. venosa** Btlr. (52 g). Above brown. Forewing in the middle of the distal margin obscurely dusted with brownish red-yellow. Beneath there are 3 red-yellow spots at this place. The hindwing is somewhat lighter brown beneath, with the veins dark brown. Peru, Bolivia.
- acraeida*. **L. acraeida** Btlr. (Trophonina a. Rüb.) (52 g). Above reddish brown with a row of 6 red-yellow spots before the distal margin of the forewing, posteriorly becoming smaller and nearer to the margin. Beneath the ground-colour of the forewing is somewhat lighter brown, the red-yellow macular band is as above, the space between this band and the distal margin is yellow-brown, intersected by the dark brown veins and interneural longitudinal lines. The yellow-brown colour is continued along the costal margin to the base. The hindwing is entirely yellow-brown beneath with the veins and interneural longitudinal lines dark brown. The markings of the under surface mimic those of the Acraeids. ♀ dimorphic, the basal half of the forewing pale reddish, that of the hindwing of a leaden hue, distal half of both wings yellow-brown. On the forewing 2 red-yellow longitudinal streaks are placed before the apex. The two colours of the hindwing shade gradually into one another. The under surface is paler and without the leaden gloss. Ecuador (Riobamba, Huamboya), Peru, Bolivia. — *malia* Godm. (= *marginalis* Stgr. i. l.) (35 a) is a form of *acraeida* in which the hindwing also bears a row of red-yellow spots before the distal margin on the upper surface. Peru (Rio Colorado, Pozuzo).

Note: *Lymanopoda varola* Schaus cf. *Manerebia cyclopina* Stgr. (p. 239).

42. Genus: **Pedaliodes** Btlr.

An extensive genus, characterized by the more or less undulate or angled form of both forewing and hindwing. Only the costal vein of the forewing is inflated at the base; median and submedian not swollen. Two subcostal veins arise before the end of the cell on the forewing. The recurrent vein is not present in either wing, or is only weakly indicated. The eyes are strongly hairy and the rather long palpus densely clothed with stiff hairs. Antenna without distinctly defined club, towards the tip gradually thickened. The headquarters of the genus are the high Cordilleras of Colombia to Bolivia, from whence single species have spread to Mexico on the one hand and Brazil on the other. They replace in these districts the *Erebia* of the temperate zone. They occur far above the forest-region, often in great numbers, frequenting wet places on the road; when disturbed they do not fly up, but seek to hide themselves among the stems of the plants nearest at hand. A very large number of the forms cited here are given by HEWITSON and other authors as *Pronophila*, hence the synonymy of this genus requires careful attention.

Poesia Group.

- poesia*. **P. poesia** Hew. (53 b). As in most species of this group, the forewing is obtusely cut off at the apex. The upper surface is unicolorous dark brown. On the under surface, before the apex of the forewing, is placed a light grey spot finely dotted with brown, on the hindwing a small white spot at the costal margin and a white dot at the anal angle. The ♀ is lighter beneath. It has a light brown, obscure submarginal band on the forewing and a distinct light brown band on the hindwing, which is marbled with dark brown and bears some white dots. A second form of the ♀ is **phanaraea** Hew. (= *phanaraea* Thieme) (53 b, erroneously called *pelinaea* on the plate). It is distinguished from the type-form by having on the underside of the forewing in the middle of the submarginal band beside the white dots several chestnut-red spots placed one behind another. Co-

lombia (Salto de Tequendane [STÜBEL], Quindiu Pass, Rio Vitavo [FASSL]), Ecuador (Huamboya [STÜBEL]).

P. japhleta Btlr. (♂ = polemon Sm.) (53 b, erroneously called *phanaraca* on the plate) is rather like *japhleta*. the preceding species, but differs in the large, triangular white spot at the inner margin on the underside of the hindwing. The ♀ of this species also possesses the rust-red spots before the middle of the distal margin on the underside of the forewing which are present in *phanaraca* and are wanting in the ♂, and the latter was described by GR.-SMITH as *polemon*. Merida (Venezuela).

P. pelinaea Hew. (= *apicalis* Stgr.) (53 b, erroneously called *japhleta* on the plate). Upper surface *pelinaea*. dark brown, before the apex of the forewing with 2 white spots and some white dusting before and behind them. On the under surface these spots are widened into a band, which is continued to the middle of the distal margin. The underside of the hindwing shows a curved row of small spots formed of white dusting and some white dots between them. Bolivia (San Jacinto, Loco Valley, Corvico and San Antonio). The further locality "St. Domingo", given by THIEME from the Tring Museum, is still doubtful.

P. hewitsoni Stgr. (53 b). The upper surface is black-brown, the fringes chequered with brown and *hewitsoni*. white. Beneath the forewing is red-brown to beyond the middle. Beyond the middle of the costal margin is placed a black-brown spot, which is sometimes continued as a dark band to the inner margin; the distal margin is dark brown; before the apex there is a whitish grey spot. Hindwing grey-brown, marbled and banded with dark brown. At the costa are placed two white spots and in cellule 2 a white dot. From Bolivia (Yungas de la Paz, Loco Valley, San Antonio). — Whether **primera** Weeks is a form of *hewitsoni* or a separate species I *primera*. cannot decide, as I have neither seen an example nor the figure. According to THIEME's description the underside of the hindwing has the anal area silver-white and 2 silver dots of unequal size; in *hewitsoni* only one of the latter is present and the former character is wanting. The rest of the markings agree. From Bolivia.

P. perisades Hew. (53 b). The species may be known by the underside of the forewing being almost *perisades*. entirely chestnut-red and by the semicircle of silver-white spots on the hindwing beneath. The upper surface is unicolorous brown. Bolivia (Corvico, Yungas de la Paz).

P. illimania Stgr. (53 c). Above black-brown, the fringes chequered with somewhat lighter brown. *illimania*. Beneath the forewing is similar to that of *perisades*, but has several small white spots before the apex. The hindwing is brown, marbled and banded with silver-grey, a row of white dots and somewhat darker distal margin. Only 1 example, taken by GARLEPP on the Illimani, in Bolivia, at an altitude of 4000 m. Koll. STAUDINGER in the Zool. Museum in Berlin.

P. phrasiela Hew. (= *perperna* Fldr., *labulla* Thieme, *phrasiela* Kirby) (53 c). Above uniform dark *phrasiela*. brown. On the under surface the species is easy to recognize by the round white spot placed in cellule 4 of the hindwing and somewhat out of alignment with the other white dots, being removed basewards; the hindwing marbled with dark brown. In the ♂ there are sometimes indications of a whitish yellow spot at the costal margin of each wing. The ♀ (53 c) has these spots larger and more distinct. In addition the submarginal band of both wings is lighter than in the ♂, and hence stands out much more distinctly. Widely distributed, Colombia (Rio Vitaco and East Cordilleras), Ecuador, Peru (Oroya), Bolivia. According to a figure prepared in the Tring Museum *Pronophila perperna* Fldr. is = *phrasiela* Hew. Hence the name *labulla* Thieme must sink. — **galaxias** Thieme is a form of *phrasiela* in which the costal spots on the under surface of both wings are large *galaxias*. and snow-white. From Peru (Oroya and Callanga) and Bolivia (Rio Songo).

P. leucocheilos Godm. & Salv. In this species the apex of the forewing is not obliquely cut off but *leucocheilos*. obtusely angled and the distal margin is rounded. Upper surface dark brown, before the distal margin with a row of white spots, extending from the costal to the inner margin, gradually decreasing in size and only separated by the broad brown veins. Beneath the forewing is dark brown, with a large whitish triangle before the apex and a red-brown longitudinal stripe, running from the base nearly to the distal margin. The hindwing is marbled with grey and brown, with 2 white spots at the costa and 2 white dots at the anal angle. This beautiful and rare species was found by SIMONS only in the Sierra Nevada, Santa Marta, Colombia and is in the Museum GODMAN and SALVIN.

P. plautius Sm. Above olive-brown, with a brownish white spot at the costal margin of the forewing, *plautius*. before the apex. Beneath the forewing is as above, except that the ground-colour is darker and the white spot larger. Along the distal margin runs a narrow stripe, irrorated with whitish. The hindwing is yellow-brown, marbled with dark brown, with a large light yellow-brown area between the veins of the median and several small spots of the same colour before the apex and in the basal area. Beyond the middle of the costal margin a white spot. A white dot in cellule 2. From Bolivia.

P. puma Thieme (53 c). Above unicolorous dark brown. Beneath the basal half of the forewing is chest- *puma*. nut-red, the distal margin brown with 4 white dots in a row before the apex. The hindwing is peculiarly marked.

It is brownish grey, with a large number of small blackish marks, each of which is of an approximately reniform, but indefinite shape, and which are arranged in transverse rows. In the middle of the costa a silver-white patch, before the apex some white dusting and at the anal angle a white dot. From Bolivia. Coll. STAUDINGER, in the Zool. Museum in Berlin.

Proerna Group.

proerna. **P. proerna** Hew. (53 c). The oldest described species of this group, which are mostly without markings. The distal margin of the forewing is rounded, that of the hindwing undulate. Above unicolorous brown. On the under surface the forewing is in places somewhat reddish, its apex and the whole hindwing marbled with grey, the latter with a white dot at the apex and another at the anal angle. Colombia (Llanos de San Martin); Ecuador (Cerro Pululagua, Huamboya); Bolivia. — **phrasa** Sm. & Kirby (53 d) is a form of *proerna* in which the posterior of the 2 white dots on the underside of the hindwing is larger and more distinct. The reddish dusting is absent, but it is somewhat dusted with grey before the apex of the forewing and in the middle of the hindwing. Also on the upper surface the costa of the forewing and the apex of the hindwing are marbled with grey. From Bolivia. — **obscura** Sm. & Kirby (= *pronoe* Stgr.) is a form similar to *phrasa*, with the upper surface brown, towards the distal margin somewhat lighter, and the incisions in the margin whitish. The 2 dots on the underside of the hindwing are of unequal size, as in *phrasa*, but in *obscura* there are often further some fine white dots towards the costal margin of both wings. Sometimes also the disc of the forewing or the anal angle of the hindwing is somewhat reddish. Bolivia. — **phrasina** Stgr. is merely a local form of *obscura* with the white dots before the costal margin on the underside of the forewing very distinct. From Yungas in Bolivia.

exanima. **P. exanima** Ersch. seems to me to belong in this group. THIEME indeed cites the species in the genus *Pronophila*, where ERSCHOFF had placed it, but ERSCHOFF's work was not at the time accessible to Herr THIEME. Through the kindness of Mr. KIRBY I had some time ago an opportunity of examining this work and was able to make notes and sketches from it. From these I judge *exanima* to be a *Pedaliodes* near to *phrasa*; ERSCHOFF describes it as follows: Expanse 55 mm., forewing with the margins entire, hindwing weakly dentate. Both wings unicolorous brown above. Beneath likewise brown, the hindwing with rather broad, somewhat lighter border, in which is placed in cellule 2, about 3 mm. from the distal margin, a distinct white dot. According to the description and ERSCHOFF's figure, which represents a female, no other dots are present. Locality: Pumamarca, Peru.

fumaria. **P. fumaria** Thieme (53 c). Upperside of both wings and underside of the forewing as in *proerna*. On the under surface of the hindwing is placed a half-band, composed of grey-white atoms, which runs from the inner margin nearly to the middle of the wing and is proximally pointed. In the ♂♂ this band is often scarcely indicated, in the ♀♀ on the contrary very distinct. Venezuela (Merida).

simpla. **P. simpla** Thieme (53 d). One of the smallest and plainest species. The distal margin of the forewing fairly straight, that of the hindwing undulate. Above dark brown, in the distal third gradually becoming somewhat lighter, in the middle of the forewing an indistinctly defined dark scent-scale spot. Beneath the colouring is lighter brown, almost without dark marbling. A minute, scarcely visible white dot in cellule 2 of the hindwing, in the Peruvian examples entirely absent. Ecuador (Baños), Peru (Huancabamba, Guzco).

empusa. **P. empusa** Fldr. (= *dryas* Stgr. i. l.) (53 d). Above unicolorous brown, fringes of the forewing chequered with brown and white, those of the hindwing with brown and light brown. On the under surface the forewing is irrorated with light brown before the apex, at the costa there is a white spot and in cellules 2—5 four white dots in a straight row. Hindwing finely striated with brown all over, a white curved spot at the costal margin and two white dots in cellules 2 and 3. From the neighbourhood of Bogotá and Muzo in Colombia and from Guzco (Peru).

poetica. **P. poetica** Stgr. (53 d) is very like *empusa*, and according to THIEME may be regarded as a Bolivian form of this, but the forewing is more rounded at the apex and on the underside of the forewing the row of dots and the costal spot are absent, while on the other hand there are at the costal margin 4 fine white dots at fairly uniform distances apart and below them some sparse white dusting. The underside of the hindwing is sprinkled all over with fine white dusting, especially at the distal margin. The white spot at the costal margin of this wing is larger than in *empusa* and divided into 2 parts by the subcostal vein. The fringes on both wings are unicolorous brown above and beneath, not chequered. Hence I regard *poetica* as a good species. From Cocapata in Bolivia. — **exul** Thieme (53 e) is a form of *poetica* in which the dark brown scent-scale spot on the upperside of the forewing extends from the inner margin to the base and the fine whitish dusting on the underside of the hindwing and at the costal margin of the forewing is absent. The white spot at the costal margin of the hindwing is smaller. The fringes are brown as in *poetica*. The most southern form of the species. Rio de Janeiro.

naevia. **P. naevia** Thieme resembles *proerna* above, being dark brown with narrow scale-spot. Beneath some-

what lighter. The forewing has here 4 white dots at the costa as in *poetica*, of which the second, reckoning from the apex, is extended into a small spot. Before the middle of the distal margin a rather small, sharply defined chestnut-red wedge-spot. Hindwing ferruginous, but little clouded, with an indistinct dark discal band, a very small, obscure grey costal spot and a white dot at the anal angle. From S. Inez in Ecuador.

P. auraria *Thieme* (53f). Upper surface brown with very large, straight-margined scale-spot, extending to the costal and inner margins. Beneath lighter brown, at the costal margin irrorated with dark brown and gold-yellow, mixed with silver-white scales. Fringes chequered with brown and white. The hindwing beneath marbled with brown and black-brown, with a row of white submarginal dots and a bright gold-yellow costal spot, such as otherwise only recurs in *pullantias* *Hew.* From Vilcanota in Peru. 2 ♂♂ in coll. STAUDINGER in the Zool. Museum in Berlin.

Prosa Group.

P. prosa *Stgr.* (= *phrasina* *Sm.*) (53 f). Above dark black-brown, the scent-scale spot only reaching as far as the posterior end of the cell. Under surface brown, both wings with a broad lighter brown submarginal band, traversed in the middle by a row of white dots. The dot in cellule 2 of the hindwing is larger than the rest. At the costal margin of this wing a white spot, at the inner margin sometimes an obscure red-brown one. From Bolivia (Loco Valley, San Jacinto, Yungas de la Paz). — **phrasiclea** *Sm.* (53 d) is a form of *prosa*, chiefly differing in the absence of the white costal spot on the underside of the hindwing, the presence of a distinct rust-red spot at the inner margin of this wing and of a grey band in the cell of the forewing. From Bolivia. — **phrasis** *Sm.* (53 e) is a form in which the darkening has proceeded still further. The basal half of both wings is entirely dark brown and only the distal part of the submarginal band is perceptible, while only the white dots stand out distinctly. From Bolivia.

P. pheretiades *Sm. & Kirby* (= *subtangula* *Stgr.*) (53 f). This species may be known by the snow-white apical spot on the underside of the forewing, below which is placed a brownish red-yellow spot. The upper surface is dark brown, in the middle of the forewing with a velvety scent-scale spot, distally lighter. The white spot of the under surface shows through above, but is here light brown. — In the form **suffumata** *Stgr.* this spot is dull white on the upper surface, somewhat dusted with brown. The red-yellow spot on the under surface is often joined to the white apical spot. Bolivia, 1500—3000 m.

P. emma *Stgr.* A beautiful species; upper surface brown with 4 oval white spots before the distal margin of the forewing, which decrease in size posteriorly, except that the 3rd is somewhat smaller than the 4th. On the under surface the last 2 white spots are placed in broad black rings, otherwise they are as above. The underside of the hindwing is as in *pheretiades*. From the Rio Songo (prov. Yungas de la Paz in Bolivia).

P. panthides *Hew.* (= *panthius* *Kirby*) (53 f). Upper surface unicolorous brown. Beneath the forewing is red-brown in the basal half, distally marbled with brown and dark brown and with 2 dark transverse bands. Hindwing marbled with light and dark brown and with a darker band across the middle, a row of darker spots before the margin and 2 or 3 white dots. Bolivia (Yungas de la Paz, Cocopata).

Perperna Group.

P. perperna *Hew.* (= *Pronoph. satyroides* *Fldr.*) (53 c). Above dark brown, distally somewhat lighter, the ♀ with a black, white-pupilled eye-spot in cellule 2 of the forewing, which in the ♂ is usually replaced by a round black spot, but may sometimes also be entirely absent. In single cases, however, this spot has also in the ♂ a white pupil. On the under surface the eye-spot is always large with a distinct white pupil, a second eye-spot is placed in cellule 2 of the hindwing and a further round white spot before the apex of the forewing. In the ♀ these eye-spots and dots on a yellowish grey, sometimes somewhat reddish, submarginal band, striated with brown. In the ♂ this band is less distinct. Costa Rica, Panama (Chiriqui), Colombia (Cauca Valley, Carmen, 1600 m.), Venezuela (Caracas). — **petronius** *Sm.* is a form of *perperna*, distinguished by the larger size of the ♀ (65 mm. in expanse). The apex of the forewing is somewhat more produced, otherwise the shape is as in *perperna*, the somewhat prominent angle at the 3rd median vein of the hindwing being also present. The upper surface of both wings is velvety dark brown, the distal third of the forewing is somewhat lighter. The eye-spot of *perperna* is absent above. On the under surface the submarginal band of both wings is broader and more distinct. Proximally to this band is placed at the costal margin of the forewing a brownish white triangle and at the costal margin of the hindwing a brownish white spot. The eye-spot on each wing and the white dot in cellule 5 of the forewing are as in *perperna*. The male is still undescribed. From Valdivia in Colombia. Coll. GROSE-SMITH.

Pisonia Group.

- pisonia*. **P. pisonia** Hew. (53 f). Above unicolorous brown, lighter towards the distal margin. Beneath lighter brown, finely dark marbled, beyond the middle with an angled dark brown transverse stripe, followed distally by the somewhat lighter submarginal band, and with a more or less distinct row of white dots on both wings. The dot in cellule 2 of the hindwing is bordered with black. The ♀ is lighter brown above and has on the forewing a dark brown band. — **manis** Fldr. (53 e) is a form of *pisonia*, differing in its smaller size and in having the inner margin of the hindwing beneath rust-red, this colour varying in its extent. The forewing is also less elongate and its distal margin somewhat more rounded than in *pisonia*. The ♀ of *manis* likewise differs from the ♂ in the lighter colouring above and beneath. Both forms occur in the high mountains of Venezuela, Colombia, Ecuador, Peru and Bolivia. — **dejecta** Bates (= *lithochalcis* Btlr.) (54 a) is likewise a form of *pisonia*, distinguished by the rust-brown gloss between the medians on the underside of the forewing. From Costa Rica, Guatemala, Panama. — **circumducta** Thieme, a further form belonging here, very near to *dejecta*, has on the upperside of both wings a broad submarginal band of glossy, light olive-brown colour. The scale-spot on the forewing is not so large as in *dejecta* and more divided into streaks. This form reaches furthest north of all the *Pedaliodes*. It inhabits Mexico. Coll. STAUDINGER (formerly SOMMER), now in the Zool. Museum, Berlin.
- manneja*. **P. manneja** Thieme (= *Pronoph. pisonia* Hew. var., *Pedal. manis* Kirby) differs from *pisonia* in having the upper surface unicolorous brown, not lighter distally, and in having a white costal spot on the underside of the hindwing. The submarginal band on the forewing beneath is only distinct proximally, becoming obsolescent distally. From Venezuela. The locality "Colombia" is uncertain. The butterfly is only represented in old collections and has not been found for the last 50 years.
- pomponia*. **P. pomponia** Hew. Shape as in *pisonia*. Above olive-brown. Forewing with a light golden brown submarginal band of moderate breadth, which is proximally rather sharply defined. The under surface is grey-brown, mostly with dark brown undulate markings, both wings with a black-brown bordered submarginal band, on the forewing of a light wood-colour, on the hindwing light grey-brown and strongly sprinkled with dark brown. From Ecuador (Pishcourco and Santa Inez).

Panyasis Group.

- amussis*. **P. amussis** Thieme (54 a). This species may be recognized by the almost straight costa of the hindwing, the apex of which is sharply rectangular, a form which does not occur elsewhere in *Pedaliodes*. For the rest the margin of both wings is obtusely dentate, with a somewhat prominent angle below the apex of the forewing. Above unicolorous brown, the tips of the fringes in the incisions white. Beneath the forewing is olive-brown with broad, somewhat lighter submarginal band, on which is placed a row of white dots, and with the apex brown, marbled with white. The hindwing is marbled with light and dark brown beneath, with several rows of dark brown spots, 2 white costal spots and a row of white dots. Colombia (province of Cauca).
- phanias*. **P. phanias** Hew. (54 a). Above unicolorous brown, before the distal margin somewhat lighter. Beneath with dark brown transverse lines, dark striation and lighter submarginal band on both wings. The ♀♀ are sometimes very large (cf. pl. 54 a). The early stages have been described by W. MÜLLER. The full-grown larva is nearly 3½ cm. in length, thickened in the middle and terminating in 2 short anal points. The face is quadrate, brown, bordered with black, the cheeks are dark grey, the dorsal part light grey, the vertex bearing 2 short, obtuse, conical horns. The body is light grey with grey-green lateral stripes and in addition on the first 3 segments with a darker longitudinal stripe. Above the stigmata are placed posteriorly ascending lines. The larva lives on bamboo and is suspended free for pupation. The pupa is dull white and light grey. It has several obtuse angles and irregularities in the middle and 2 moderately long horns. The butterfly is distributed in South Brazil in the provinces of Minas Geraes and Parana and also occurs in Paraguay. — **granulata** Btlr. is a large form of *phanias* in which the central area on the underside of both wings is marbled with dark brown and with the distal boundary uniformly dentate. Thus the light submarginal band on both wings is not broader at the inner than at the costal margin. From Colombia (Bogotá). — **silpa** Thieme, a small form of *phanias*, has the apex of the forewing somewhat more pointed and the distal margin straighter. On the under surface there are two darker transverse stripes in the cell of the forewing. On the hindwing a dark median band runs from the middle of the costal to the middle of the inner margin, and is strongly excurved in the middle of the wing. From Bolivia (Illimani, Yungas, de la Paz), Peru (Limbani), Ecuador (Huamboya).
- panyasi*. **P. panyasis** Hew. (54 a). Above red-brown. Forewing with some white dots at the costal margin before the apex, which is almost rectangular. Fringes chequered with brown and white. Beneath the forewing is likewise red-brown, at the costal margin and before the apex marbled with dark brown and grey. The hindwing is light and dark marbled throughout, with two dark dentate transverse bands particularly prominent,

one before, the other behind the middle. At the distal side of each of these bands is placed a row of quadrate whitish yellow spots, the first of which are close to the costal margin. From Merida (Venezuela) and Bogotá (Colombia). — *mara* Thieme is a form of *panyasis* in which the underside of the forewing lacks the wood-yellow line beyond the middle, which is replaced by bronze-yellow dots placed parallel with the distal margin. The hindwing is in parts somewhat copper-red. From Bolivia (Yungas de la Paz).

P. drymaea Hew. (= *Daedalma* d., *angularis* Btlr.) (54 a). The upper surface is dark brown, in the distal third of the wing changing gradually into light brown. The fringes brown, chequered with light brown. On the under surface the apex of the forewing is strongly dotted with white, before it a yellowish line similarly as in *panyasis*. The marbling of the hindwing is much darker than in *panyasis* and is condensed into dark transverse bands. Between these is placed at the costa a whitish spot, which is continued as a straight, light brown stripe to the middle of the wing and is here lost in the marbling. By this stripe the species is easy to recognize. The ♀ is like the ♂. HEWITSON gives Colombia as locality, where FASSL has also recently found both sexes at the Cipaque and at the Quindiu Pass at altitudes of 3000 m. This is interesting inasmuch as THIEME questioned its occurrence in "New Granada", i. e. Colombia. The species occurs also in Bolivia (Yungas de la Paz) and Peru (Aqualani). — *rahhab* Thieme, the Peruvian form of *drymaea*, is somewhat larger than the latter, with the wings less dentate and the distal margin of the forewing less produced. The upper surface is unicolorous bronze-brown, not lighter distally. Beneath the wings are lighter brown with rust-red apex and grey atoms at the costal margin. The scheme of markings on the hindwing is as in *drymaea*, but darkened with rust-brown. A small spot on the costa and a larger one at the apex are distinctly lighter. Peru (Chaliabamba, 3300 m.).

P. tomentosa spec. nov. (54 b). Size of *drymaea*, the apex of the forewing somewhat more produced, distal margin of the hindwing undulate. Above black-brown, the fringes lighter brown between the veins. Beneath olive-brown, the costal margin of the forewing with several small, white-powdered spots before the apex. Hindwing finely striated with dark brown all over, with 2 indistinct brown dentate lines before and beyond the middle. The inner and distal margins are sprinkled near the apex with fine whitish grey powdering, suggesting the appearance of mildew. In cellule 2 and in cellule 3 a white dot. From Bogotá. 2800 m. Discovered by FASSL.

P. muscosa Thieme (54 b). Above brown with large, darker scale-spot on the forewing and a whitish spot on the costa of the hindwing. Beneath the forewing is olive-brown with a yellow-brown submarginal band, which is anteriorly bent basewards. Before the apex a white-dusted triangle and 3 white dots. Hindwing similar to *panyasis*, marbled with light and dark brown, in the anterior part strongly dotted with white, so as to form in the basal area 2 lighter bands and before the apex a lighter half-band. Bolivia (Yungas de la Paz, Corvico, San Antonio), Colombia (Alto de las Anees, 2200 m., FASSL).

P. jephtha Thieme (54 b) resembles *muscosa* in the scheme of markings, but the forewing is not rounded, but forming an acute angle at the apex, its distal margin not produced, but nearly straight; at the same time distinctly and sharply dentate. Above unicolorous brown. On the under surface of the forewing the apex is not spotted with pure white but powdered with grey and a row of grey spots is placed along the anterior part of the costal margin. Hindwing dark marbled and crossed by 2 distinct white oblique bands, with dentate margins, one from the middle of the inner margin straight to the middle of the costa, the other as a half-band from the inner angle to the 3rd median vein. From the Cordilleras on the coast of Colombia (province of Antioquia).

P. niveonota Btlr. Above pitch-black. Forewing beneath ferruginous with brown costa and a quadrate brown spot at the end of the cell, behind it a conical yellow spot; a grey submarginal band with 3 white dots; distal margin broadly brown. Hindwing beneath olive-brown, sprinkled with black and silver-grey dots, across the middle a silver-grey band which becomes white at the inner margin, a silver-grey spot at the apex, several small spots of the same colour before the distal margin and between them a row of silvery dots. From Huasampilla in Peru (3000 m.) (WHITELY). Only in the British Museum.

Pammenes Group.

P. pammenes Hew. (54 b) may be recognized by the reddish cinnamon colouring in the distal half of both wings above. The distal margin in the forewing is rounded, the fringes chequered with brown and white. The under surface is similar to the upper, but lighter. On the costa of the forewing behind the middle a light brown spot and before the apex 3 white dots. Hindwing red-brown with a broad, light red-brown submarginal band, dentate at the edges and striated with dark brown, in which is placed a row of white dots in black rings. In the middle of the costa a narrow whitish spot. Bolivia (Rio Chaco, Rio Tanampaya, San Antonio). — *garleppi* Thieme is the mountain form of *pammenes*, in which the submarginal band on the under surface is indistinct and the eye-spots placed in it are indistinct or entirely absent. From Cillutincara (3000 m.) and other high mountain localities in Yungas de la Paz (Bolivia).

- antulla*. **P. antulla** *Thieme* has the extreme apex of the forewing not rounded, but somewhat produced. The upper surface is unicolorous dark brown, the scale-spot does not extend into the cell. Beneath: forewing dark grey-brown, only in the anterior distal half somewhat lighter with 3 white dots before the apex. Hindwing dark red-brown, the posterior half of the inner and distal margins chestnut-red. Beyond the middle a distinct lighter discal line, at the apex a silver-white hook and a silvery dot below it, and in the middle of the costa a 2nd silvery dot. The ♀ has the markings paler. Limbani, Upper Peru.
- daulis*. **P. daulis** *Thieme* (54 b). Forewing with rather sharp apex, above unicolorous brown, the scale-spot small and triangular. Beneath lighter brown; the dark basal half of the forewing is separated from the distal part by a light line, which does not quite reach the inner margin. Below the apex 4 white dots. On the hindwing the discal line is somewhat undulate and extends from the costal to the inner margin. A row of white dots before the distal margin, the first widened into a spot. A further white dot beyond the middle of the costa. From Callanga in the province of Cuzco in Peru.
- patizathes*. **P. patizathes** *Hew.* (= *palizethes Kirby*) (54 c). Above unicolorous brown. Beneath marbled with somewhat lighter brown, with a reddish brown submarginal band on the forewing. The hindwing with a white costal spot, joined to the costal margin by a fine point. From Ecuador (BUCKLEY), Quindiu Pass in Colombia, 2800 m. (FASSL).
- paeonides*. **P. paeonides** *Hew.* (= *Pron. porcia Hew.* on HEWITSON's plate) is near the preceding species, but the forewing is not truncate. The upper surface is reddish brown, darkest in the middle of the forewing. The under surface is reddish brown, the hindwing dark sprinkled. The forewing as well as the hindwing has a costal spot, but both are very small and dull white. A small, narrow dirty white stripe runs from the 3rd median vein to the inner margin near the anal angle, by which the species may be known. From Ecuador. — **P. costipunctata** *form. nov.* (54 c). I regard as the Colombian form of *paeonides*. It is deep black-brown above, only at the distal margin of the forewing somewhat lighter for a breadth of about 3 mm. The small costal spots on the under surface consist on both wings of only a few white scales, and the fine white transverse line in the posterior part of the hindwing is also composed of single, widely-separated scales. Fringes dark brown. Distinguished from *simmias*, to which it has also some resemblance, by the entire absence of the rust-red colour. From Monte del Eden, Ibague, Colombia, 2700 m., December (FASSL).
- pallantias*. **P. pallantias** *Hew.* is reddish brown above, darkest in the middle of the forewing. Beneath reddish brown, striated with dark brown. Costal spots large, that of the forewing 4 mm. in length, triangular, that of the hindwing 10 mm., in the middle angularly bent, reddish yellow. From Ecuador.
- uniformis*. **P. uniformis** *spec. nov.* (54 c). Forewing with the apex rectangular. Above dark reddish brown, fringes in the anterior half of the forewing between the veins with whitish tips, otherwise brown. Under surface of the same colour, with only a trace of a small, somewhat lighter brown costal spot at $\frac{2}{3}$ of the costal margin visible on both wings. In addition a brownish white dot in cellule 2 of the hindwing. The white tips of the fringes on the forewing as above. From Bolivia.

Phanoclea Group.

- phanoclea*. **P. phanoclea** *Hew.* The species of this group are distinguished by the elongate hindwing. *phanoclea* is brown above, towards the anal angle of the hindwing red-brown. Beneath the forewing is brown with a short white band at the costa, the hindwing yellow-brown, striated with dark brown, traversed by a straight wood-yellow median band and with a row of 4 black dots with white centres. Ecuador.
- porcia*. **P. porcia** *Hew.* (= *Pron. paeonides* on HEWITSON's plate) 54 c). Recognizable by the light yellow half-band at the apex of the hindwing beneath. The upper surface is unicolorous brown. Ecuador (BUCKLEY).
- albutia*. Colombia (Monte Socorro and Quindiu Pass, 3500 m., FASSL). — **P. albutia** *Thieme* is a somewhat larger form with the light half-band on the underside of the hindwing twice as broad and not light yellow but pure white. The costal spot on the underside of the forewing is also pure white. From Peru.
- phthiotis*. **P. phthiotis** *Hew.* may be recognized by the tripartite white costal spot on the hindwing beneath. The forewing has a small costal spot, which is indicated on the upper surface also. Otherwise the colouring is brown. Ecuador.
- simmias*. **P. simmias** *Thieme* (54 c). Above unicolorous brown. Beneath little lighter, towards the apex of the forewing and at the anal angle of the hindwing mostly ferruginous. Forewing with indistinct costal spot. The transverse band beyond the middle of the hindwing is likewise sometimes very indistinct, as also the light dots in the disc. From Bolivia (Yungas de la Paz).

Piletha Group.

- piletha*. **P. piletha** *Hew.* (= *pedacia Stgr.*) (54 c, d). May be known by the white half-band, anteriorly running

out into a point on the underside of the hindwing. The upper surface is unicolorous reddish brown. In the ♀ the posterior half of the distal margin of the hindwing has sharper and more pointed teeth. Venezuela, Colombia, Paraguay. — **pedacia** Hew. is a form of *piletha* in which the white half-band on the underside of the hindwing is somewhat broader at the inner margin and connected with the costal spot by a sinuous row of small white spots. Ecuador.

P. prytanis Hew. has the hindwing very dark, with the half-band reduced to an oblique, quadrate white spot at the inner angle. The costal spots are very indistinct. The upper surface is dark brown, only spotted with white in the incisions of the strongly dentate margin of the forewing. Venezuela, Colombia. — **phoenissa** Hew. (54 d) is perhaps a form of the preceding. It only differs in having the distal margin of the forewing not dentate, but merely weakly undulate. Colombia.

P. phazania Sm. (54 d) may be known by the straight course of the white half-band of the hindwing from the inner margin to between the radials, while it gradually decreases in breadth and terminates in a fine point. Ecuador. — **cestia** Thieme is probably only a form of *phazania*. The half-band of the hindwing is almost the same shape, but is sulphur-yellow, not white. Colombia.

Tena Group.

P. tena Hew. (54 d). The species of this group have the wings more elongated. *tena* may be recognized by the row of 4, in the ♀ 5, white spots on the upperside of the forewing, which are larger in the ♀, smaller in the ♂. In the ♀ there are in addition to this row one or two white dots before the apex of the forewing, and a row of 4 white dots on both surfaces of the hindwing. The latter are sometimes present also in the ♂ on the upper surface. On the underside of the forewing some of the white spots are sometimes absent. — THIEME regards the following large-spotted species *pasicles* as the ♂ of *tena*. Thus he has overlooked that HEWITSON himself says in the 5th volume of his "Exot. Butt." that ♂♂ of *tena* have smaller white spots than the ♀, which he figured. I have seen 10 examples of *tena* collected by STÜBEL, including 9 ♂♂ which all had smaller spots than HEWITSON's figure. One of them is figured on our plate. I am therefore compelled to regard *pasicles* as a separate species. *tena* flies in the high mountains of Ecuador at the snow-line (Páramo de Cuvilche, 3800 m., Antisuna, 4300 m.).

P. pasicles Hew. Above brown, the distal margin somewhat more rounded than in *tena*. Forewing with 3 light yellow spots beyond the middle, the first large, 6 mm. in length, divided by a vein into 2 parts, the other two small, especially the last. On the under surface the 2 small spots are absent and there is a black submarginal line. Ecuador (Alatillo).

P. reissi Weym. (54 d). On the upper surface an indistinct row of dots beyond the costal spot, which stands out more distinctly beneath. Hindwing lighter brown, finely marbled with dark brown. The ♀ was discovered by FASSL on Monte Tolima and only differs from the ♂ in having the dark brown marbling on the underside of the hindwing more prominent on account of the lighter ground-colour and in the presence of a brownish grey submarginal band, strongly dentate distally, before the distal margin. The costal spot of the hindwing is dusted with brownish beneath. On the Páramos of Tolima, of Moras and of Huila, 3600—4200 m. (STÜBEL, FASSL).

P. albonotata Godm. (54 d). The white spot wanting on the under surface. The hindwing beneath has 2 dentate whitish transverse stripes, which are strongly speckled with brown. In the distal area a row of white sagittate marks, the anterior 2 larger and more distinct. Venezuela (Merida).

P. albopunctata Weym. (54 e). Under surface like the upper, which is here figured. The number of dots varies on the hindwing from 1 to 4. In the ♀ the underside of the hindwing has a broad yellowish brown submarginal band, in which are placed the white dots in dark rings. Peru (Cruz de Celendín, Páramo, between Marañon and Utcubamba, 3000—3600 m.); Bolivia (Quimtachata, Tiahuanaco, 4200 m.). — **flavopunctata** Stgr. is a form of *albopunctata* with straw-yellow instead of white dots. From Bolivia.

P. perita Hew. Size of the preceding. Above unicolorous brown, only the fringes of the forewing spotted with white. Forewing beneath with the margins marbled with grey and with a row of 4 white dots. Hindwing beneath with broad grey-yellow submarginal band, on which are placed 5 white dots in black rings. Ecuador.

P. nebris Thieme (54 e) may be easily known by the short, straight honey-yellow band beyond the middle on the upperside of the hindwing. Beneath this band is whitish yellow and between it and the distal margin are placed 4 white dots in black rings. Sometimes there is also on the underside of the forewing a transverse row of 4 small reddish yellow spots and beyond them a row of white dots. The former are sometimes present on the upperside also. The ♀ does not differ from the ♂ in markings. — According to FASSL the egg is spherical, bone-yellow, glossy and entirely covered with fine pitting. He found the butterfly in various localities in the Colombian East Cordilleras, rarely below 3300 m., and suspects that the types described by THIEME from the STAUDINGER collection were also taken there.

empetrus. **P. empetrus** *Thieme* (54 e). Above yellow-brown with a submarginal row of white dots, larger on the forewing, smaller on the hindwing. Fringes chequered dark brown and white. The butterfly seems to be rare in collections. Venezuela (Merida).

Polusca Group.

paneis. **P. paneis** *Hew.* (54 e). Above unicolorous brown. The rust-red band of the under surface rises from the inner angle of the hindwing and runs $\frac{2}{3}$ across the wing, gradually tapering to a point. Beyond this
tyro. a row of white dots. Peru, Bolivia, Colombia. — In the form **tyro** *Thieme* (= *paneis* *Hew. pt.*) (54 f) the rust-red band on the under surface is much shorter, occupying barely $\frac{1}{3}$ of the breadth of the wing. Only one white dot, placed at the anal angle. The apex of the forewing is truncate, forming a right angle.
pheres. Peru. — **pheres** *Thieme* (54 f) is a further form, in which the apex of the forewing is not truncate, but the distal margin is straight throughout, and the white dot at the anal angle is wanting. The rust-red band has about the same extent as in *tyro*. Peru, Bolivia.

philonis. **P. philonis** *Hew.* (54 e) is a similar species to *paneis* with the apex of the forewing truncate. The red-yellow band on the underside of the hindwing is as long as in *paneis*, beyond it is placed a light brown submarginal band, strongly dentate distally, which bears a row of 5 black eye-spots with thick white pupils. Ecuador, Peru.

pheretias. **P. pheretias** *Hew.* (54 f) may be known by the elongate white costal spot on the underside of the hindwing. The red-yellow anal spot is rather small. The upper surface is unicolorous black-brown. The ♀ was found by FASSL at the Quindiu Pass, Colombia, in 2 different forms. One is similar to the ♂, only differing in the presence on the underside of both wings of a broad grey-brown submarginal band, on the hindwing reaching the white costal spot and the rust-red inner-marginal spot and marbled with dark brown.
griseola. The other female form (pl. 54 f), for which I propose the name **griseola** *form. nov.*, only differs in having the ground-colour of the entire underside of the hindwing yellowish grey-brown, finely striated all over with dark brown, so that the costal and anal spots have almost disappeared. From the Quindiu Pass (FASSL).

ferratilis. **P. ferratilis** *Btlr.* (= *morenoi* *Dogn.*) (54 f). Above dark brown, beneath lighter brown marbled with dark brown, the hindwing with broad ferruginous inner margin, from which arises a quadrate, light rust-red
uncus. anal spot. Peru, Ecuador, Bolivia, Colombia. — **uncus** *Thieme* is a form of *ferratilis* in which the rust-red colour on the underside of the hindwing is confined to a narrow distal border, and which bears 4 white dots on the underside of the forewing. From Tucuman in North Argentina.

zoippus. **P. zoippus** *Druce*. A small species of 46 mm. expanse, above brown with the inner margin and anal angle of the hindwing red-brown. Under surface the same, the hindwing with some indistinct white spots before the distal margin and a dark brown submarginal line. Peru.

polusca. **P. polusca** *Hew.* (54 f). Above dark brown with narrow red-brown border at the inner angle. On the under surface distinguished by the 2 subanal white dots beyond the red-brown submarginal band of the hindwing, which is more or less extended. The larger, typical *polusca* occurs both in Colombia
polla. (where FASSL took it on Mont Socorro at altitudes of 3500 m.) and in Peru and Bolivia. — **polla** *Thieme* (= *polusca* *Hew. pt.*) is a smaller form, in which the rust-red band on the underside of the hindwing runs up to beyond the cell. The inner angle is much lighter yellowish rust-red. The ♀ does not differ from the ♂.
syleus. From Colombia (Quindiu Pass, 3800 m., FASSL). — **syleus** *Thieme*, a further form of *polusca*, in which the rust-red colour on the underside is confined to the transverse band of the hindwing only, there being no rust-red colour present at the anal angle and in the rest of the distal part of both wings. From Limbani, Peru.

asconia. **P. asconia** *Thieme* is a species similar to *polusca*. The transverse band beyond the middle of the hindwing on the under surface consists only of a quadrate orange-yellow spot at the inner margin and 3 small honey-yellow spots beyond the middle of the wing. A white dot between median veins 1 and 2. The ♀ is pale brown above, bordered with rust-red at the anal angle. The under surface of the forewing shows a pale costal spot. From Baños in Ecuador (HAENSCH).

pausia. **P. pausia** *Hew.* (= *loca* *Stgr.*, *lora* *Sm.* & *Kirby*). Above dark brown, distally reddish brown. Beneath the same, forewing with 2 or 3 very small white dots before the apex, hindwing with a narrow, light rust-red
lucipara. half-band, which crosses a row of 4 white dots. Bolivia (Yungas de la Paz). — **lucipara** *form. nov.* (55 a) is a form of *pausia* in which the upper surface is not reddish distally, but only lighter brown. On the under surface the white dots of the forewing are absent and the hindwing shows only 2. From the Quindiu Pass,
baccara. 2500 m., Colombia (FASSL). — **baccara** *Thieme* is a form which has on the forewing beneath a broad light brown submarginal band, finely bordered with white distally. The transverse band of the hindwing is twice as broad as in *pausia* and only in its posterior part rust-red. From the Colombian province of Antioquia (KALBREYER).

P. coca *Stgr.* (55 a) is allied to *pausia*, but the row of dots consists of 6 and they are differently placed. From Cocapata in Bolivia (GARLEPP).

P. entella *Thieme.* The distal margin of the forewing is emarginate below the apex. Above unicolorous dark brown with grey fringes. Beneath: forewing light brown with rust-brown apex; hindwing dark red-brown, with light ferruginous marbling, a ferruginous band arising from the inner margin and spots of the same colour beyond it between the median veins; a row of small black, white-pupilled dots in the same position as in *coca*. Baños in Ecuador (HAENSCH).

P. proculeja *Thieme* has the distal margin of the forewing below the apex emarginate as in *entella*. Above unicolorous brown. Beneath lighter. Forewing with whitish costal spot and rust-brown apex. Hindwing brown with light rust-brown spots, yellowish towards the base, and an elongate-triangular, obscure, light yellow half-band between the inner margin and the middle of the wing. A row of blackish dots with white centres before the distal margin. From Urcos in Peru (GARLEPP). Tring Museum.

P. tucca *Thieme* (55 a). Above unicolorous dark brown with broad scale-spot. On the underside of both wings some confluent spots forming more or less distinctly a chestnut-red submarginal band; beside this band a row of white dots. The figure has been prepared from an example in coll. THIEME. From the neighbourhood of the Illimani in Bolivia. — **luperca** *Thieme* is a form of *tucca* in which the scale-spot on the upper surface is half as broad. The ground-colour of the underside of the forewing is not light brown but dark brown and the chestnut-red band is absent. Santa Inez in Ecuador.

Pactyes Group.

P. cledoina *Thieme* (55 b). Above glossy brown; the rust-red transverse band on the underside of the hindwing is anteriorly dusted with yellow and broken up into spots. A white dot is placed in cellule 2. From Yungas de la Paz and Cillatincara (Bolivia).

P. antonia *Stgr.* (55 a). The broad band on the upperside of the hindwing has a projecting branch and is present in the same shape on the under surface, but here light ochre-yellow. San Antonio and Cillatincara (Bolivia), Chiri-Mayo (South-East Peru). — **anina** *Stgr.* is a form of *antonina* in which the band of the hindwing is only represented on the upper surface by a short light grey spot at the costa and on the under surface the lateral branch of this band is much shorter. Loco Valley in Bolivia. — **quincedis** *Thieme* (55 b), the more copiously ornamented Peruvian form of *antonina*, differs from the latter in the large quadrate white spot on the forewing above and beneath. The band of the hindwing is bright sulphur-yellow above, with silky golden gloss, beneath as in *antonina*. Callanga in Peru. — **exsanguis** *Thieme* is a further form belonging here, and differs from *quincedis* in having the whole of the markings snow-white. Callanga, Peru.

P. pactyes *Hew.* Above brown. Forewing with the fringes chequered with brown and white, hindwing with an indistinct reddish wood-yellow median band which shows through here from the underside. Beneath it is orange and somewhat angled. A white dot in cellule 2. Bolivia. — **auristriga** *Thieme* is a form in which the upper surface is unicolorous dark brown and the underside of the forewing bears a distinct costal patch. The band of the hindwing is narrow and light saffron-yellow. Huancabamba in North Peru. **serra** *Thieme*, in which the yellow band forms a short point distad on vein 2, and **stilla** *Thieme*, in which this band is broken up into separate spots, are forms of *auristriga* from the same locality. — **spina** *form. nov.* (55 b) is a further form belonging here, unicolorous black-brown above and showing on the underside of the forewing a distinct whitish costal spot which is continued as a reddish brown band to the inner margin. Across the middle of the hindwing runs an anteriorly white, posteriorly ochre-yellow band, which in cellule 6 forms a sharp angle proximad, in cellule 4 an angle distad. In addition, opposite to the latter angle a white streak or tooth runs along the median as far as the cell. In the somewhat lighter distal area a row of 5 white, black-edged dots, in the (55 b) there is also a row of similar dots on the forewing. Found at the Quindiu Pass in Colombia (3800 m.) in September by FASSL.

P. chrysotaenia *Hpffr.* (55 b), a species similar to *pactyes*, may be recognized by the brown irroration on the under surface of the hindwing, across which runs a golden yellow band from the anal angle round the cell to the costa, broad posteriorly, but in the anterior half only quite narrow and forming several angles. From Peru (Chanchamayo and Huancabamba). — **fassli** *form. nov.* (55 b), a similar form to the preceding, has the distal margin of the forewing less undulate, and the ground-colour of the under surface is not marbled, but dark brown. The hindwing has a white, bipartite costal spot and a half-band running up from the inner angle, anteriorly narrowed and distally curved, also a few whitish dots between the end of this band and the costal spot. From Monte Socorro, 3400 m., Colombia, July (FASSL). Named in honour of the discoverer.

Peucestas Group.

- peucestas*. **P. peucestas** Hew. (55 c). Above dark brown; forewing with the same white band as beneath. The ♀ is quite like the ♂ except that the broad submarginal band on the underside of the hindwing is much lighter whitish grey. Colombia (Quindiu Pass, Salto de Tequentama), Peru, Ecuador (Baños), locally common.
- porina*. **P. porina** Hew. (= *Tisiphone lyssa* Burm.) (55 c). Differs from the preceding species in the shorter white band above and beneath and also in the absence of the white spots on the underside of the hindwing.
- palaeopolis*. Ecuador (Baños, Huamboya), Bolivia (Rio Pongo, Yungas de la Paz), North Argentina (Tucuman). — **palaeopolis** Hew. is a form of *porina* which on the underside of the forewing bears a small blackish, white-pupilled
- corderoi*. eye-spot at each side of the white band. From Bolivia and Limbani in Peru. — **corderoi** Dogn. (55 c) is a further form in which the light brownish grey submarginal band on the underside of the hindwing is broader and is also visible on the upper surface as a washed-out yellowish brown band. From Loja and Macas in Ecuador.
- porima*. **P. porima** Sm. (= *porrima* Stgr.) (55 c). The white band on the forewing extends into cellule 2, which is not the case in the 3 preceding forms. Further recognizable by the 3 to 5 whitish yellow dots on the underside of the hindwing, of which the middle one is somewhat larger. Bolivia.
- pallantis*. **P. pallantis** Hew. (55 c). The white band takes in the anterior part of the cell and extends nearly to the inner margin. The distal margin of the hindwing is obtusely angled. The ♀ is somewhat larger and has the forewing concave below the apex. Colombia (Monte Socorro, 3500 m.), North Peru (Huancabamba).
- pylas*.  **P. pylas** Hew. (= *pilas* Hew. in tabula) (55 c). The 2 white spots of the forewing are present also on the upper surface. The hindwing on the contrary is unicolorous dark brown above. Colombia (Bogotá). — In the form **uniplaga** Thieme the small white spot at the costal margin of the forewing is absent. Colombia. —
- uniplaga*. **parma** Thieme is a very similar form, in which the small spot is likewise absent, but the large spot is somewhat further removed from the distal and inner margins and placed nearer to the costa. On the under surface this spot is somewhat larger and takes in a part of the cell. From the coast Cordilleras in Colombia (KALBREYER).
- phaedra*. **P. phaedra** Hew. Above brown with a bright primrose-yellow band across the forewing and a large spot of the same colour in the middle of the hindwing. On the under surface the yellow band of the forewing is broader than above and the spot on the hindwing is prolonged anteriorly and posteriorly into a complete
- melaleuca*. band. **melaleuca** Weym. (= *Pronoph. palades* Hew.) (55 d) is a form of *phaedra* in which all the yellow markings are milk-white. Transitions occur between the two forms. The name *Pron. palades* Hew. cannot be retained for this form, as HEWITSON himself had previously described another species under the name *Pronophila palades* (the present *Lasiophila palades*).
- niphoessa*. **niphoessa** Thieme (55 d) is another form of *phaedra*, with the band of the forewing chalk-white and somewhat broader, occupying the distal part of the cell. The white spot on the underside of the hindwing is in both forms prolonged to the inner margin. From the Quindiu Pass in Colombia, 3500 m. (THIEME and FASSL).

Plotina Group.

- plotina*. **P. plotina** Hew. (55 d). May be known by the large red-yellow spot before the anal angle of the hindwing above. Beneath this spot is ochre-yellow, marbled with brown, and from it a straight ochre-yellow
- rapha*. stripe runs up to radial 2, where it is followed distally by a white dot. Venezuela. — **rapha** Btlr. (= *plotinella* Sm.) (55 d) is a form of *plotina* in which the red-yellow spot on the upperside of the hindwing is smaller and shorter. On the under surface of the hindwing the ochre-yellow stripe is broken up into crescent-shaped spots and from the end of the stripe a row of white dots runs to the costal margin. Venezuela. — In the
- pharnaspes*. form **pharnaspes** Hew. (55 d) the separate spots of the yellow band on the hindwing are not crescent-shaped, but elongate-quadrate, of the row of dots only one is present and before the distal margin on the underside of the forewing there is a broad, light reddish brown band. Venezuela, Ubalá (Colombia, East Cordilleras). FASSL.
- cocytia*. **P. cocytia** Fldr. (= *phaesana* Hew. [in tabula]) (55 d). Above unicolorous dark brown. On the underside of the hindwing is placed between the narrow, straight ochre-yellow band and the distal margin a curved row of grey-brown spots. The yellow band is often broken up into small, more or less widely separated spots. In a ♀ captured by FASSL (55 d) the separate spots are proximally pointed. The figure of the ♂ has been prepared from FELDER's type in the Tring Museum. — The egg is spherical, milk-white, somewhat transparent. The surface is smooth and glossy. From the plateau of Bogotá, 2600—3200 m.
- hopfferi*. **P. hopfferi** Stgr. (55 e). The broad red-yellow band of the hindwing is strongly sprinkled with dark
- tyrrheus*. brown on the under surface and extends to the apex. From Cuzco and Huancabamba in Peru. — **tyrrheus** Godm. & Salv. is probably only a form of *hopfferi* Stgr. The red-yellow submarginal band of the hindwing is shorter, only extending from the inner margin to one-half the wing. On the under surface it is ochre-yellow, somewhat longer than above and anteriorly pointed. Sierra Nevada of Santa Marta (Colombia). SIMONS.

Parepa Group.

P. parepa Hew. (55 e). Recognizable by the narrow red-yellow macular band on the upper surface *parepa*. of both wings. Beneath the forewing is exactly as above except that the apex is marbled with grey. The distal half of the hindwing is similarly marbled. The dark brown basal area forms a right angle in the middle. From Ecuador (Huigera, Guishapa, Loja). — **milvia** Thieme is probably the Peruvian form of *parepa*. The *milvia*. red-yellow band is confined to the anterior part of the forewing and is entirely absent on the hindwing. Distal half of the hindwing grey-brown beneath, with 2 black ocelli standing out distinctly. From Chosico in Peru (850 m.). There is only one female example, in the Tring Museum.

P. phaea Hew. Both wings traversed beyond the middle by a brownish red-yellow band, which on the *phaea*. forewing is divided into oval spots. In the ♀ the bands are broader and not divided on the forewing. The under surface is similar to that of the figured *ochrotaenia*, but the bands are narrower. Ocanna in Colombia. — **ochrotaenia** Fldr. (55 e) is a form of *phaea* in which the band on the upper surface is not divided; in the ♀ *ochrotaenia*. it is broader (6 mm.) and more ochre-yellow. From Bogotá (Colombia). — **fuscata** Fldr. (55 e), a further form *fuscata*. belonging here, has the broad band on the upper surface strongly suffused with smoke-brown, obliterating its edges. On the under surface, on the other hand, the band is not ochre-yellow but more red-yellow. From Bogotá (Muzo), Páramo de Guasco. — In **amafania** Thieme, another *phaea* form, the red-yellow band is placed *amafania*. nearer to the margin and runs parallel with it throughout. Its margins are smooth, nowhere interrupted and not angled, merely somewhat ventricose in the middle of the hindwing. Beneath the band is light ochre-yellow and there is a white spot at the costa of the hindwing and another at the anal angle. From Callanga (province of Cuzco) in Peru. Coll. STAUDINGER in the Berlin Museum.

P. alusana Hew. The red-yellow band is placed somewhat beyond the middle. It is broadest in the *alusana*. middle of the forewing, narrowest at the inner margin of this wing; at radial 1 on the hindwing it is interrupted on the upperside and forms a right angle on the underside. There are also here in the distal area of the hindwing some ochre-yellow spots and a row of white dots. From Alusana in Ecuador (Coll. HEWITSON, Brit. Mus.).

P. praxia Hew. Above brown with a red-brown band beyond the middle of the forewing, running parallel *praxia*. with the distal margin, and a red-brown costal spot on the hindwing. On the under surface of the forewing this band is much broader posteriorly and is white at its origin, on the costal margin. A red-brown spot is placed in the cell. From Jima in Ecuador.

P. thiemei Stgr. (55 f). The dark red-yellow band, which runs from the costal margin of the forewing *thiemei*. to the inner margin of the hindwing, is somewhat lighter on the underside of the forewing, but on the hindwing ochre-yellow, covered with brown speckling. In the ♀ the band is about a third broader beneath than in the ♂. From the Quindiu Pass in Colombia (3800 m.). THIEME, FASSL.

P. peruda Hew. Above brown with a broad, straight red-yellow band beyond the middle, which is *peruda*. pointed at the costal margin of the forewing and the inner margin of the hindwing. Beneath the band is even broader than above, on the forewing red-yellow, on the hindwing nearly white, somewhat marbled with brownish. The distal margin of both wings is dusted with grey. Amazon. Coll. Brit. Mus.

P. symmachus Godm. & Salv. Above dark brown with a dark red-yellow band 3 mm. in breadth *symmachus*. running across both wings near to and parallel with the distal margin. On the underside of the forewing the band is broader and lighter red-yellow. On the hindwing beneath 2 ochre-yellow stripes occupy the place of the band. Sierra Nevada of Santa Maria in Colombia.

P. ornata Sm. (= *phaeaca* Stgr.) (55 f). The red-yellow band of the forewing is as strongly curved *ornata*. proximally on the underside as on the upper. The hindwing beneath has an ochre-yellow transverse band, which forms a right angle on the lower radial. Beyond it is placed a row of white dots in brown rings. Merida (Venezuela).

P. phaeina Stgr. (= *Pronoph. phaea* var. Hew.) (51 b). On the forewing the band is only very weakly *phaeina*. indicated, but on the hindwing it is bright red-yellow and occupies almost half the breadth of the wing. On the under surface this band is light ochre-yellow on the hindwing, proximally straight-edged and distally dentate; finely sprinkled with brown, with a row of white, brown-bordered dots. Pacho (3000 m.) in the Colomb. East Cordilleras (FASSL); Central Cordilleras of Colombia (THIEME).

P. pelinna Hew. (55 e). May be known by the obliquely placed yet straight band of the forewing. The *pelinna*. band of the hindwing is anteriorly constricted, and forms in the middle 2 distally directed teeth. The colour of the bands is bright ochre-yellow. Beneath the bands are the same, only much lighter. Ecuador (Rosario, Villagomes, Macas).

P. parrhoebia Hew. Recognizable by the rose-red colour of the band, which forms two angles on the *parrhoebia*. forewing and one on the hindwing, and has its proximal edge quite irregularly dentate. On the under surface the forewing is as above, on the hindwing the band is broken up into several light brown spots. From Galgalan in Ecuador.

- phintia*. **P. phintia** Hew. The upperside is similar to that of the preceding species, as is also the underside of the forewing, except that it bears a small light brown spot in the cell and the apex is broadly light brown, marbled with black. The hindwing beneath has a straight white band before and a light brown band beyond the middle, proximally margined with white. A black spot with white centre is placed anteriorly in this band and 2 similar ones before the distal margin. From Jima in Ecuador.
- philotera*. **P. philotera** Hew. (55 e). The dark red-yellow band forms an acute angle on the hindwing. On the under surface the hindwing is brown, crossed by 2 ochre-yellow parallel stripes which arise from a costal margin of the same colour and divide off a dark pointed triangle proximally and a long quadrate patch in the middle of the wing. Colombia (Páramo de Guasco, 3000 m. [STÜBEL], Quindiu Pass, 3500 m. [FASSL]).
- phoenicusa*. **P. phoenicusa** Hew. One of the largest species of the genus, with an expanse of 70 mm. The forewing is pointed, the distal margin dentate. Brown. Forewing with a distally curved red-yellow transverse band beyond the middle. Hindwing only with a red-yellow spot at the costal margin. Beneath the forewing is as above, except that it bears in addition a red-yellow spot in the cell and a grey spot at the apex. Hindwing beneath grey, marbled with brown, with a broad, lighter, dentate submarginal band, on which is placed a row of white, black-edged dots. Ecuador. Very rare. Only in coll. HEWITSON (Brit. Mus.).

Physcoa Group.

- physcoa*. **P. physcoa** Hew. Above brown with a large, obliquely placed, oval red-yellow patch at the anal angle of the forewing. Beneath the distal half of both wings is marbled with grey and brown, the red-yellow spot as above. From Bolivia (Yungas de la Paz, Corvico). — **marulla** Thieme (56 a) is a form of *physcoa* in which the red-yellow spot does not rise obliquely but steeply, thus running nearly parallel with the distal margin. From Chanchamayo in Peru.
- ereiba*. **P. ereiba** Fldr. (= Pron. pasicrates Hew.) (55 f). May be known by the broad red-brown submarginal band on both surfaces of the forewing, which is dark brown. Figured from FELDER's type in the Tring Museum. Bogotá (LINDIG), La Vega, Colombian East Cordillera, 2200 m. (FASSL). — **cremera** Godm. & Salv. (erroneously called *cremona* on the plate in the "Biologia Centrali-Americana") is a form of *ereiba* Fldr. in which the band is more red-yellow and is curved basewards at the costal margin. On the under surface this band bears between the first and second median vein a small black, white-pupilled eye-spot. On the hindwing the last 2 eye-shaped dots in the submarginal row before the anal angle are larger and more distinct. From the Volcan Irazu in Costa Rica.
- praxithea*. **P. praxithea** Hew. (56 a). A large and beautiful species. The red-yellow band is present also on the underside of the forewing. The hindwing is brown beneath, striated with dark brown, with a transverse band irrorated with whitish beyond the middle. Bolivia, Ecuador (St. Rosario, Villagomes).
- triaria*. **P. triaria** Godm. & Salv. (56 a) is near to *praxithea* but is smaller and the red-yellow border of the hindwing extends to beyond the middle. Beneath the red-yellow band of the forewing is broader than above, and before the apex of the forewing, as well as before the distal margin of the hindwing, there is a row of white dots. From the Volcan Irazu in Costa Rica.
- phila*. **P. phila** Hew. (55 f). Somewhat smaller even than the preceding, but likewise similar to *praxithea*. The band on the hindwing only reaches median vein 3. The underside of the hindwing is uniformly marbled all over with light and dark brown, only with the apex ochre-yellowish. Bolivia (Yungas de la Paz), Peru (Calanga). — **philaenis** Thieme is a form of *phila* in which the band of the forewing runs straight and reaches the distal margin above the distal angle. Of the red-yellow spots at the apex of the hindwing only an obscure ochre-yellow submarginal line remains. On the under surface there is a white triangle at the apex of the forewing. From Baños in Ecuador.
- pandates*. **P. pandates** Hew. Above brown with a broad ochreous marginal band, which in the anterior half of the forewing is broken up into spots, in the posterior half of this wing and on the hindwing is placed quite near to the distal margin, only leaving a narrow brown border. On the under surface the band has the same position and colour as above, but both wings are densely striated with dark brown. In the ♀ the band is pale yellow and nearly twice as broad as in the ♂. Bolivia (Yungas de la Paz, Corvico, Rio Songo). — **pamphos** Thieme (56 a) should probably be regarded as only a form of *pandates* with the band entirely absent on the upperside of the forewing, but on the under surface scarcely differing appreciably. From Yungas de la Paz in Bolivia.
- napaea*. **P. napaea** Bates resembles on the upper surface the form *pamphos*, but is different beneath. Here both wings are traversed by a sharply defined submarginal band, on the forewing grey, on the hindwing yellowish with a pupilled eye-spot between the first and second median veins. Guatemala.

Juba Group.

- juba*. **P. juba** Stgr. (= *cyrene* Sm. & Kirby) (56 b). Above brown, beyond the middle of both wings with a

row of yellowish brown or dark chestnut-red spots, which stands out but little on the dark ground and on the hindwing is angled and abbreviated. The under surface is irrorated with yellow-brown. The band of the hindwing is here ochre-yellow and reaches the inner margin with a large spot. Ecuador. — **triquetra** *Thieme triquetra*, is a form of *juba* which has on the underside of the hindwing in the anterior part of the disc a dark brown triangle on a light ground. Ecuador.

43. Genus: **Eretris** *Thieme*.

The forewing is broader and shorter than in the genus *Pedaliodes*, its distal margin is more rounded, whilst that of the hindwing is weakly undulate. The principal character of the genus consists in the shape of the inner margin of the hindwing, which shows a distinct excision before the anal angle. Antenna brownish yellow, with the separate joints somewhat thickened at their upper end and hence forming distinct rings. Its shaft is short, the tip obtuse, black. The butterflies are mostly dark brown, below medium size, with eye-spots or leaden-hued lines on the underside of the hindwing. They occur in the mountains of tropical South and Central America.

E. decorata *Fldr.* (= *Pron. catargyrea* *Stgr.*, *phyllalia* *Stgr.*) (56 b). Above unicolorous dark brown, *decorata*, distally somewhat lighter. Beneath easy to recognize by the very complicated pattern, which the figure distinctly reproduces. From Bogotá and Antioquia in Colombia. — **mariona** *Weeks* (= *Pedal. m.*) is a form of *decorata* *mariona*, in which the dark brown submarginal line on the underside of the forewing is proximally finely bordered with brick-red and the markings of the hindwing are more suffused with yellowish. The red-yellow bordering of the eye-spots is only narrow, not broad. Bogotá.

E. porphyria *Fldr.* (56 b). Above unicolorous brown. Beneath the hindwing has a straight red-yellow *porphyria*, median line, proximally bordered with lilac. Beyond the row of small eye-spots 2 lilac undulate stripes at the margin. Figured from *FELDER*'s type in the Tring Museum. Venezuela.

E. ocellifera *Fldr.* (56 c). Above brown, the hindwing with a very small subanal ocellus, the anal *ocellifera*, angle grey, slightly dusted with rust-yellow. On the underside of the hindwing before the eye-spots there is a proximally red-yellow, distally ochre-yellow, anteriorly pointed stripe, running from the inner margin to the middle of the wing. Figured from one of the types in the Tring Museum. Colombia.

E. encycla *Fldr.* (56 c). Above unicolorous brown. Beneath the proximal part of the hindwing is *encycla*, tinged with ochreous fawn-colour, the eye-spots are larger than in *ocellifera*, the space beyond them as far as the submarginal lines is filled up with glossy lead-colour. Figured from *FELDER*'s type in the Tring Museum. Venezuela.

E. calisto *Fldr.* (56 b). Above dark brown, distally somewhat lighter. On the under surface of the hindwing the eye-spots are broadly bordered with glossy lead-colour both basally and distally and midway between the submarginal lines is placed a leaden line. Bogotá and Veja in the Colombian East Cordilleras.

E. oculata *Fldr.* (56 d). Hindwing above with small subanal eye-spot dusted with rust-yellow. Beneath *oculata*, the wings are as in *encycla*, but the marginal area of the hindwing is not glossy leaden but violet-grey; the proximal stripe red-yellow, proximally bordered with black-brown. The eye-spots are surrounded with pale yellow-brown. Figured from the type in the Tring Museum. Bogotá.

E. apuleja *Fldr.* (56 b). Above brown, at the anal angle of the hindwing red-yellow, which colour *apuleja*, occupies the posterior third of the distal and inner margins. On the underside of the hindwing an ochre-yellow band, anteriorly red-yellow, runs to the middle of the wing, becoming narrower anteriorly. The anal angle is red-brown. The eye-spots are very small. Venezuela. — **phyllalia** *Hew.* is a form of *apuleja* with two small, white-*phyllalia*, pupilled black spots in the red-yellow anal patch on the upper surface. Ecuador.

E. hulda *Btlr. & Druce* (56 c). Above brown, at the anal angle somewhat reddish, with dark submarginal *hulda*, line. Forewing beneath with 3 transverse lines between middle and distal margin. The anal third of the hindwing beneath is ferruginous, traversed by an interrupted yellow stripe and with 2 eye-spots before the anal angle. According to the "Biologia Centrali Americana" *BUTLER* described this species from a damaged specimen in coll. *DRUCE*. Hence *GODMAN* and *SALVIN*'s diagnosis and figure in the above work agree but little with the original description. Costa Rica. The species seems, however, to be more widely distributed, for the example from coll. *WEYMER* figured here, which agrees with the figure just mentioned, is from Ecuador.

E. subpunctata *Sm. & Kirby*. Brown. Forewing beneath with 2 dark transverse lines in the middle *subpunctata*, and 2 before the margin. Hindwing at the base dark brown, in the middle somewhat reddish, then a ferruginous dentate stripe, bordered with dark brown at both sides, and a grey-brown band with 6 small, black, white-pupilled eye-spots. At the distal margin 2 ferruginous marginal lines. From Bolivia. — **umbrina** *form. nov.* *umbrina*, (56 c) approaches *subpunctata*, but differs from it in the presence of 2 anal eye-spots on the upperside of the hindwing, one in cellule 1 c near the distal margin, the other in cellule 2 somewhat further from the margin, both black with light brown ring and white pupil. For the rest the upper surface is dark brown, at the margin

somewhat lighter with fine, dentate, darker submarginal line on both wings and 2 marginal lines, which are straight on the forewing, angled on the hindwing. On the under surface a yellowish grey band runs from the inner margin to the middle of the wing, where it is gradually lost in the ground-colour. The ferruginous dentate stripe with black bordering terminates close to the inner angle, whilst in *subpunctata* it runs into the inner margin 3 mm. from the angle. The dark grey band which follows, containing the eye-spots, shades off lighter distally. Of these eye-spots the first 4 are somewhat indistinct. Found by FASSL at Monte Tolima, Colombia, at 3200 m. in January.

subrufescens. **E. subrufescens** Sm. & Kirby (56 c). Above unicolorous brown. Beneath: hindwing in the distal half entirely reddish brown, with dark transverse bands beyond the middle and before the distal margin, and between them a row of small black ocelli with white pupils. Costa Rica. From Monte Socorro, 3600 m., Colombia (FASSL).

rubricaria. **E. rubricaria** Thieme. ♂ small. Above brown. Hindwing with thin honey-yellow marginal line and a small anal eye-spot. The ♀ upperside has on the forewing, in addition to a lighter, distinctly defined submarginal band (which is anteriorly broader, posteriorly narrower), an indistinct pale reddish line, on the hindwing two pale reddish lines, one discal, the other submarginal, and on each wing a honey-yellow marginal line. Beneath both sexes have on the forewing one, on the hindwing two glossy leaden lines before the distal margin and on the hindwing 6 eye-spots. Colombia. Berlin Museum.

ochrea. **E. ochrea** Thieme. Above dark brown with reddish gloss. Forewing beneath lighter with 3 dark transverse lines and a yellow marginal line. Hindwing beneath at the base and the costal margin darker, in the anal part brownish ochre-yellow with 4 red-brown transverse lines, one at the base, the second in the disc before the eye-spots, the third and fourth before the distal margin. The row of eye-spots consists of 5 or 6 small black ocelli with white pupils. A triangular ochre-yellow band runs from the inner margin to the disc, where it is broken up into 3 small spots. Ecuador. Berlin Museum (HAENSCH).

44. Genus: **Lasiophila** Fldr.

Head small, densely haired, with a tuft of hairs projecting forwards, eyes hairy, palpus porrect, three times as long as the head, the first joint short, the second long, the third with obtuse, densely haired tip; antenna short and thin. The costal of the forewing is inflated at the base, the median and submedian only somewhat thickened. Two subcostal veins arise before the end of the cell. The principal distinguishing character of the genus consists in its having the costal margin of the hindwing excised, the excision extending from the base to $\frac{2}{3}$, a character that only recurs in *Daedalma*, which genus, however, differs in other respects. The hindwing is dentate and has 2 small tails, the proximal one shorter than the other. The middle discocellular of both wings forms an angle proximad, from which arises a small recurrent vein. In the markings on the underside of the hindwing the species are all very similar. The area of distribution of the genus embraces the countries between Venezuela and North Argentina, where the butterflies are met with in the high mountains, sometimes gregariously.

cirta. **L. cirta** Fldr. (= *Pronoph. praeneste* Hew. pt.) (56 e). The largest and most beautiful species of the genus, recognizable by the large milk-white spot on the hindwing. The double row of rust-red spots before the distal margin on both wings stands out in many examples more distinctly than in the figure. The under surface is similar to that of the figured *persepolis* (56 c), except that the basal area of the forewing is brown to beyond the middle. From Peru (Rio Sonchi, 2300 m. [STÜBEL], Chanchamayo, Rioja, Huancabamba). — *diducta* Thieme is a form of *cirta* with the rust-red spots on the upperside of the forewing proximally extended to the cell, the last 2 even joined to the rust-reddish basal part. From Huancabamba in North Peru.

piscina. **L. piscina** Thieme (56 d). The under surface of the forewing entirely resembles the figured upper surface except that the red-brown ground-colour is somewhat lighter. The underside of the hindwing is like that of *phalaesia* (56 d), thus the white spot is not present. Cuzco (Peru).

prosymna. **L. prosymna** Hew. The white band of the forewing is present above and beneath and does not quite reach the 2nd median vein. Under surface marbled with grey or brown, and with a dentate row of small yellowish white spots. Colombia, eastern slopes of the Bogotá Cordillera, 2000 to 2500 m., Subida del Tesari, 2300 to 2500 m. (STÜBEL). Quindiu Pass, 2800 m. (FASSL). — *dirempta* Thieme (55 f) is a form which differs so little from *prosymna* as to be scarcely worth naming. The white band is somewhat narrower and is constricted in such a way as to separate off its last spot. Ecuador. — In the form *orbilia* Thieme the chestnut-red markings of the upper surface are replaced by a brown colour, which is somewhat lighter than the rest of the ground-colour. Colombia.

phalaesia. **L. phalaesia** Hew. (56 d) was first described by HEWITSON as the ♂ of *prosymna*, but he afterwards recognized it as a separate species. Above brown with the base broadly reddish brown. Forewing with broad red-yellow submarginal band, posteriorly rust-red, distally smooth-margined, but with its proximal margin somewhat uneven, and continued in 3 smaller spots on the apex of the hindwing. Ecuador. — *regia* Stgr. (56 d) may probably be regarded as a form of *phalaesia*. The submarginal band of the forewing

is on both surfaces distally somewhat dentate, proximally more strongly angled and more chestnut-brown. The spots at the apex of the hindwing are larger and continued to beyond the middle of the distal margin. From Bolivia and Peru. — **confusa** Stgr. (56 d), a further from belonging here, is smaller than the preceding two. *confusa*. The markings of the upper surface are different, especially on the hindwing, and the ground-colour in the basal half lighter brown. From Ecuador.

L. persepolis Hew. (56 e). May be recognized by the strongly dentate dark brown median band on *persepolis*. the upper and under surface, which interrupts the chestnut-red submarginal band on the 2nd median vein of the forewing. The basal part of both wings is chestnut-brown to the inner angle. Ecuador.

L. hewitsonia Btlr. Above chestnut-brown, the distal half of both wings dark brown with 2 rows *hewitsonia*. of chestnut-brown spots, the distal row on the forewing not reaching the apex. The under surface is like that of *phalaesia*. Bolivia. — **neda** Thieme is probably to be regarded as a form of *hewitsonia*, with the two *neda*. rows of spots golden chestnut-red and both reaching the costal margin of the forewing. The separate spots are also narrower and longer and the dark brown ground-colour extends somewhat further basad at the costal margin of the forewing. From Limbani in Peru.

L. circe Fldr. (= Pronoph. praeneste Hew.) (56 e) has the dark brown distal margin narrower than *circe*. in *hewitsonia* and only traversed by one row of chestnut-red spots. The under surface is nearly as in the allied species and has a row of white dots in the disc of the hindwing. The ♀ only differs from the ♂ in the lighter red-brown colouring above and beneath. Colombia (Bogotá and East Cordillera). — **cnephas** Thieme *cnephas*. is a form of *circe* in which the distal part of both wings is entirely darkened, so that all the red-brown spots are scarcely perceptible. From Salento (Colombian Central Cordillera).

L. palades Hew. (57 a) is a species similar to *circe*, which differs in the darker, but at the same time *palades*. brighter brown-red ground-colour and the smaller, lighter golden-brown and differently placed spots in the distal margin. The spot in cellule 2 of the forewing is long, bipartite, the inner part widely removed proximad, also the anterior spot is placed nearer the base. Beneath the forewing is brown-red with a row of red-yellow spots. From Ecuador. Rare.

L. zarathustra Thieme. Wings broad, forewing somewhat truncate at the apex. The outer tail of the *zarathustra*. hindwing broad and spatulate. All the markings very indistinct, the chestnut-red of the base and spots is scarcely distinguishable from the black-brown distal margin. The spots of the forewing are large and broad and proximally extend into the basal part. Somewhat more distinct is a triangular spot below the apex. The spots of the hindwing resemble those of *circe*. From Papallacta on the Chimborazo.

L. behemoth Thieme is the shape of *zarathustra*, but the inner tail of the hindwing is wanting. Mark- *behemoth*. ings and colouring on the other hand similar to those of *circe* Fldr. Before the distal margin only one row of spots, which do not extend into the basal part. Only the spot in cellule 2 of the forewing is larger and accompanied by a small brown spot. This spot and also the costal spot of the forewing and two in cellules 4 and 5 of the hindwing are brilliant light red. Colombia. Rare. Coll. MAASSEN in the Zoolog. Museum, Berlin.

L. parthyene Hew. Above dark brown with red-brown submarginal band, which on the forewing is *parthyene*. narrow and bears a black spot before the apex. Before the latter, close to the costa, a white spot. On the hindwing this band is broader and bears 5 black spots. Beneath the forewing is red-brown at the base, the band is red-yellow, the white spot somewhat larger. Hindwing beneath much as in the allied species. Galgalan in Ecuador.

L. zapatoza Westw. (56 e). The smallest and the first published species of the genus. The spots *zapatoza*. in the brown distal margin of the forewing are more yellowish than the red-brown basal part. On the under surface almost the whole of the apex is yellowish and the hindwing bears a straight row of 4 small white spots. Venezuela.

L. sombra Thieme (57 a) approaches *zapatoza*, but differs so much in the larger size and darker colour- *sombra*. ing that it may probably be regarded as a good species. Above dark chestnut-brown, apex of the forewing broadly, distal margin narrowly black-brown. The marginal spots but little lighter than the basal part. Beneath the forewing is somewhat lighter than above, the apex marbled with grey and brown. The base and inner margin of the hindwing are similarly marbled; the distal part is for the most part filled up with brown, with a row of 4 white spots. Cordillera of Bogotá, Colombia.

L. orbifera Btlr. (57 a). Above bright brown-red. Forewing with broad black-brown distal margin, *orbifera*. which reaches to the cell, with 5 rather large, bright brown-red spots in a curved row. The hindwing with narrow margin and 5 brown spots before it. Under surface as in *zapatoza*. Bolivia. — **intercepta** Thieme *intercepta*. is a form of *orbifera* in which the brown-red spot in cellule 2 of the forewing is absent and on the hindwing the 3 anterior black-brown spots are confluent with the distal margin. From Baños in Ecuador. In the form **munda** Thieme the ground-colour is brilliant chestnut-red, the dark distal margin is narrower and *munda*. the red spot in cellule 2 is absent as in *intercepta*. Huancabamba (Peru), 3000 m. — **pura** Thieme, a fur- *pura*.

ther form belonging here, is distinguished by the chestnut-colour appearing almost golden red. The markings are nearly black and sharply defined. The row of spots in the distal margin of the forewing is replaced by a continuous submarginal band of particularly brilliant colour. From Tucuman in North Argentina. — In *semipartita* form. nov. (57 a) the dark brown distal margin of both wings is so broad that the dividing-line from the light brown-red basal half runs through the middle of the wing and the butterfly is consequently very similar to *Megalura hermione*. On the margin there are on the forewing only 2 small light brown-red spots and anteriorly a short streak, on the hindwing a light brown-red line. The under surface is as in *orbifera*, but the light spots in the distal margin of the forewing very small. From Manaure.

ciris. **L. ciris** Thieme (56 e) is similar to *zapatoza*. The forewing rather short with the apex almost rectangular. The tail of the hindwing is short and obtuse. The chestnut-brown ground-colour is much darkened and shades into the colour of the broad distal margin. In the latter a row of chestnut-brown spots. The submarginal row of black-brown spots on the hindwing is partly connected with the distal margin. From Ecuador and Colombia.

45. Genus: **Daedalma** Hew.

Head and eyes hairy. Palpus long projecting. In the forewing 2 subcostal veins arise before the end of the cell. The apex of this wing is obliquely truncate, the distal margin forms a right angle on the upper radial and below this is somewhat excised. The first and second median veins of the hindwing terminate in 2 obtuse tails which project straight out and do not bear the shaggy hair of the following genus. The costa of the hindwing is strongly excised. The few species are very similar and inhabit the Cordilleras from Venezuela to Bolivia, where they fly singly at especially high altitudes, above the tree-limit, and are all rare.

dinias. **D. dinias** Hew. (= *boliviana* Stgr.) (56 f ♂ upper and under surface, 51 b ♀). The form described and figured by HEWITSON from Colombia is not entirely dark on the underside of the forewing, as STAUDINGER states (Iris X, p. 139), but has the same red-yellow spots as on the upperside, for HEWITSON says in the text to the *dinias* plate in vol. 2 of his Exotic Butterflies that the underside of the forewing is "as above" and only mentions differences as regards the apex of the forewing and the hindwing. Thus this is the same form which STAUDINGER received from Bolivia and calls *boliviana*, and the latter name must consequently sink. The original *dinias* form with the red-yellow spot on the underside of the forewing has been taken by FASSL in both sexes in the Colombian East Cordilleras at Pacho (2200 m.) and at Monte Tolima (3200 m.). It is distributed across Peru to Bolivia. As the form with the dark under surface of the forewing is now without a name, I propose for it the name **oenotria** form. nov. (56 f). On the upper surface the red-yellow spot is still present, but removed further from the costa than in typical *dinias*. *oenotria* occurs at Bogotá. In an intermediate form between *dinias* and *rhomboides*, which I call **rhomboides** form. nov. (56 f), the red-yellow spot is of an obliquely quadrate shape and only its short inner angle enters the cell. From Bolivia.

inconspicua. **D. inconspicua** Btlr. Size and shape of *dinias*, except that the tails of the hindwing are somewhat longer and thinner. Above brown with some clouding, otherwise without markings. Beneath the forewing is grey with a brown band beyond the middle. The underside of the hindwing agrees entirely with that of *dinias* in markings and colouring. The ♀ is still unknown. From Quito and Papallacta on the Chimborazo. Rare.

drusilla. **D. drusilla** Hew. Shape of *dinias*, but smaller. Above brown with the fringes chequered with white. At the costa of the forewing before the apex 4 fine white streaks. Beneath the forewing is brown with a yellow-grey spot in the cell and a yellow-grey band before the distal margin, in which are placed a row of black dots. Before the apex a blue-grey spot. Hindwing beneath similar to that of *dinias*. The ♀ is not yet known. Colombia.

dora. **D. dora** Stgr. (56 f). Above almost entirely dark brown, only the tips of the fringes white between the veins. Forewing beneath brown with the apex marbled, hindwing beneath similar to that of *dinias*. The ♀ occurs in 2 somewhat different forms, one with a brownish ochre-yellow submarginal band on the upperside of both wings, in which are placed dark brown spots, the other with this band much infuscated and standing out but little from the dark ground-colour. On the underside of the forewing, which somewhat recalls the Palearctic *Vanessa urticae*, this band is, however, distinct in both forms. From the Bogota district, 2800—3200 m. (FASSL).

palacio. **D. palacio** Dogn. Size of the preceding species. Above brown. Forewing with a white transverse band across the middle and small white spots before the apex, hindwing with a row of small white spots from the costal margin to the middle. Beneath the forewing is as above, but the ground-colour lighter and the apex more spotted with white, hindwing similar to that of *dinias*, but with sharper dentate line and chestnut-red spots at the margin. The ♀ is not known. Loja (Ecuador).

46. Genus: **Polymastus** Thieme.

Forewing elongate, with the costal margin rather straight, the anterior part of the distal margin

produced into 3 more or less sharp points, below the upper radial strongly excised. The tails and angles of the hindwing are differently shaped in the individual species. The principal distinctive character of the genus consists in the costa of the hindwing, which is as strongly excised as in *Daedalma*, forming at the base an anteriorly directed, rounded projection. The space between the first median vein and the inner margin on the underside of the hindwing is adorned with single long hairs which grow out of the veins and lie over the surface of the wings (at least in set specimens). The tips of the tails and the projecting angles of the hindwing also show shaggy ciliation. At the inner angle 2 points are placed side by side. The species occur in the Cordilleras of tropical South America from Colombia to Bolivia, but are among the greatest rarities. The ♀♀ of the majority of the species are not yet known. Most of the forms were described as *Daedalma*.

P. doraete *Hew.* (57 a). On the under surface the light spots of the forewing are larger than above *doraete*, and lilac-coloured, between them is placed a row of eye-spots and two lilac longitudinal stripes border the cell. The hindwing has the ground-colour olive-brown, with a large number of angled silver spots and between them a row of 8 eye-spots. Colombia (Quindiu Paß, 3500 m. Mont Serrate near Bogotá, 3200 m. FASSL). Peru (Huancabamba, 3000 m. THIEME).

P. gideon *Thieme* is the shape of *doraete*, but the upper surface is wood-coloured brown, with 2 rows of lighter (not white) long spots, between which is placed a row of round dark brown spots, continued also on the hindwing. The under surface is nearly as in *doraete*. From Cushi in Peru. — **antissa** *Thieme* is a form of *gideon* in which the long light brown spots of the forewing are broader and at the ends bordered with whitish. From Huancabamba in North Peru. — **enipeas** *Thieme*, described by him as a separate species, is perhaps only a smaller form of *gideon* with the middle teeth of the hindwing shorter and the entire upper surface of more dusky colouring. The long spots of the forewing are less conspicuous, but are marked with dull white dots placed beside the dark circular spots. Under surface as in *gideon* and *doraete*. From Cillutincara and Rio Songo in Bolivia.

P. dorinde *Fldr.* (57 b). This and the following species have only one row of spots on the forewing above and beneath. The hindwing, however, bears two rows. These are yellowish white. The ground-colour of the upper surface is light brown, in the ♀ figured from the Berlin Museum lighter and more yellowish than in the ♂. Rare. Colombia (Cauca), Ecuador.

P. emilia *Btlr.* (57 b) is rather like the preceding species, but is distinguished by having the distal half of the hindwing beneath light grey and the row of eye-spots indistinct. The basal half of this wing is not dark green, as in *dorinde*, but dark grey with large silver spots. Found by FASSL at the Quindiu Pass at an elevation of 2700 m.

P. whitelyi *Druce* (57 b ♂ and ♀). On the upper surface there is in the ♂ a second row of indistinct whitish yellow spots before the distal margin of the forewing. The ♀ has the ground-colour of the upperside yellowish brown, with rows of ochre-yellow spots. Peru, Bolivia (Chaco, San Antonio, Rio Songo), Ecuador (Baños).

47. Genus: **Thiemeia** *gen. nov.*

At the end of the following genus, *Catargynnis* *Röb.*, THIEME has placed 2 species, which differ very much in shape from the other species of the genus. They have on the first two median veins of the hindwing long straight tails, as in *Daedalma*, and the distal margin of the forewing is strongly excised in the middle. On the ground of these differences I propose erecting a new genus for them, and name it in honour of the late Prof. THIEME, whose too early death has deprived entomology of a good worker at the present family. These species cannot be referred to *Daedalma*, as they lack the concave excision at the costal margin of the hindwing, which is here more smoothly rounded. The first species was described as a *Pronophila*, the second as a *Catargynnis*.

T. phoronea *Dbl. & Hew.* The distal margin of the forewing projects in an obtuse angle on the upper radial. Above unicolorous dark brown, only the fringes broadly chequered with brown and white. The shape is quite similar to the figured *ortruda*, except that the two tails are not parallel as in this, but diverge somewhat distally. The ♀ is paler brown above with a blurred white costal spot on the forewing. Beneath the forewing is brown, at the apex marbled with white, reddish, yellowish and purple-grey, the fringes as above. Hindwing reddish chocolate-coloured, in the middle darker, basally with whitish band, distally with a row of 6 brown, white-ringed spots, which are surrounded with purple-grey. Venezuela. Very rare in collections, only in the Brit. Museum ♂ and ♀, and in the Berlin Museum 1 ♀ (coll. STAUDINGER).

T. ortruda *Thieme* (57 c ♀ upper and under surface). The ♂ is unicolorous brown above and resembles the ♂ of *phoronea* on the under surface also. But the ♀ is very different. It has on both surfaces of the forewing a broad ochre-yellow band, which above is also continued on the anterior part of the hindwing. From Bolivia (Rio Songo and Cillutincara, 3000 m.). Rare.

48. Genus: **Catargynnis** Rüb.

After the 2 tailed species which THIEME referred to this genus have been removed (cf. the preceding genus, *Thiemeia*) the rest may be characterized as follows. Eyes strongly hairy. Palpus long projecting, with appressed hairs, the terminal joint pointed. Antenna with long, thin club. Forewing elongate, the distal margin fairly straight or with shallow excision in the middle, hindwing undulate, rarely more strongly dentate, occasionally somewhat produced in the anal part. In the forewing 2 subcostal veins arise before the end of the cell. The middle discocellular forms in both wings an angle proximad, from which a small recurrent veins arises. Many species have on the underside rows of silvery spots, especially on the hindwing, or silvery bands. The species occur in the high mountains from Guatemala to Bolivia, only one in South Brazil. They are mostly very rare in collections. Several species have been described as *Oxeoschistus*, some also as *Pronophila* or *Daedalma*.

- gigas*. **C. gigas** Godm. & Salv. (57 c ♂ upper and ♀ under surface). The largest species of the genus, distinguished by the broad red-yellow marginal band of the hindwing and the rows of silvery spots on the underside of both wings, which in the figured ♀ are larger than in the ♂. From the high mountains of Guatemala (Accytuno, Purula, Pansamala). Very rare.
- rogersi*. **C. rogersi** Godm. & Salv. Above brown with a broad red-yellow submarginal macular band on the forewing, on which are placed several round brown spots. Hindwing above without markings. Beneath the forewing is as above, but the hindwing similar to that of the following *phaselis*, bearing several rows of silver spots and between them a row of black eye-spots with ochre-yellow pupils and rings. From Irazu in Costa Rica and Chiriqui in Panama.
- phaselis*. **C. phaselis** Hew. Above unicolorous dark brown, beneath like the form *argyritis*, figured on pl. 57 c, but with the ground-colour of the under surface of the hindwing not dark brown but red-brown. The apex of the forewing is also red-brown, with some white spots. The ♀ is somewhat larger. From Venezuela and Colombia. — *argyritis* Thieme (57 c) is the dark Bolivian form of *phaselis*, with the ground-colour of the hindwing beneath not rust-red but dark brown and the silvery spots larger and more distinct. From Bolivia and Peru.
- pholoe*. **C. pholoe** Stgr. (= *Oxeoschistus phalsi* Gr.-Sm.) (57 d upper and under surface). May be known by the submarginal row of red-yellow spots on the forewing. Beneath the silver spots are much smaller than in the preceding species. From Colombia (Cauca).
- mirabilis*. **C. mirabilis** Btlr. Shape of *Mygona prochyta*, but the forewing shorter. Above dark brown with green reflection, fringes black, chequered with sulphur-yellow. Forewing beneath dark brown with a black, white-bordered line before the distal margin, beside it 3 black blind eye-spots, a double white subcostal spot and some eye-shaped spots in the disc. Hindwing beneath olive-brown, with two obscure silver bands enclosing a dark dentate median band, beyond it a row of 8 black, white-pupilled eye-spots with yellow iris. Huasampilla (Peru). Rare. One ♂ in the Brit. Museum.
- loxo*. **C. loxo** Dogn. (= *Pronoph. sagartia* Gr.-Sm., *Daedalma bronza* Weeks) (47 d). The species is distinguished by having the anal part of the hindwing elongated. The upper surface is unicolorous glossy bronze-brown. On the under surface the silvery bands are not well expressed. From Colombia (Bogotá, Zipapura).
- ilsa*. **C. ilsa** Thieme (47 e) has the wings less elongate than in *loxo*, the markings of the under surface much more distinct and the silver stripes in the ♂ brighter. The ♂ is unicolorous dark brown above, the ♀ more olive-brown. The tooth on the first median vein of the hindwing projects less in the ♀ than in the ♂, which is figured here. Moreover, the ♀ has the silver band on the underside of the forewing interrupted in the middle and the silver markings of the hindwing somewhat infuscated. Rare. Colombia (Cauca [coll. STAUDINGER], Rio Vitaca, 2500 m. [coll. FASSL]).
- gerlinda*. **C. gerlinda** Thieme. Similar to the preceding, but with the wings shorter and rounder. Above unicolorous brown with slight gloss. Underside of the forewing dull brown with 3 small eye-spots before the apex and indistinct lighter marginal spots; that of the hindwing is light brown shot with silvery, with a strongly dentate median band, which is interrupted in the middle, the base dark brown, a distinct row of eye-spots and a dark marginal band, strongly dentate proximally. Bolivia (Yungas de la Paz, Loco Valley, San Jacinto, Cillutincara).
- helche*. **C. helche** Thieme (57 d upper and under surface). Distal margin of the forewing obtusely projecting at the upper radial. The scheme of markings of the under surface is very similar to that of *gerlinda*, but *helche* may be at once distinguished here by the chestnut-red basal area of the forewing. The habitat is likewise Bolivia (San Antonio, Cillutincara). Rare. 2 examples, ♂ and ♀, in coll. STAUDINGER (Berlin Museum).
- asuba*. **C. asuba** Thieme. Above brown with strong coppery gloss. The forewing shows a large dusky scale-spot, extending in rays along the veins. The hindwing is more feebly dentate. On the under surface there is

a chestnut-red spot between the median veins of the forewing, by which the species may be recognized. Of the 3 silvery transverse stripes on the underside of the hindwing the proximal one is quite straight. Bolivia (Yungas de la Paz). Rare, only one ♂ in THIEME's collection.

C. mena Gr.-Sm. (58 a). Above unicolorous brown, with bronzy gloss. Beneath the silver markings *mena*. at the apex of the forewing and the silver bands on the hindwing are much darkened by brown dusting. There is mostly here on the forewing a small orange spot between the 2nd and 3rd median veins, which was wanting in the example figured. Bolivia (Yungas de la Paz, San Jacinto, San Antonio, Cillutincara).

C. clethra Thieme. Similar to the preceding, but smaller. Above glossy bronze-brown. Forewing *clethra*. beneath without gloss, dark brown, only the apex somewhat silvery. A small chestnut-red spot between the 2nd and 3rd median veins. Hindwing beneath likewise dark brown, only the anterior half somewhat silvery. There is no trace of transverse bands, on the other hand all the veins are black and each cellule bisected longitudinally by a black line, forming a pattern similar to that of the *Actinote* species. At the base are placed some small red spots. From Peru (Villanota and Chanchamayo). 2 examples in coll. STAUDINGER (Berlin Museum).

C. schreineri Foetterle (= lemur Thieme) (58 a). Above pale yellowish brown with 2 rows of light *schreineri*. ochre-yellow spots and dark grey-brown base. The hindwing is margined with reddish in the anal part. The under surface is similarly marked to the upper, except that the spots on the hindwing have a dull silvery gloss and in the basal half of this wing is placed a silver band partly broken up into spots. The ground-colour of the hindwing beneath is yellowish brown, finely striated with dark brown. Petropolis (South Brazil).

49. Genus: **Mygona** Thieme.

The costal margin of the forewing is long, its anterior part produced distad, and the distal margin consequently excised below the upper radial. The hindwing is strongly dentate, the tooth on the 2nd median vein broader and stronger than the rest, but not produced into a tail. The costa of the hindwing is not emarginate, but smooth and rounded. In the scheme of markings of the under surface the species are all very similar. On the hindwing a white spectacle-shaped spot and 3 white dots forming a triangle are nearly always present and on the forewing mostly three chestnut-red or light brown dots. The species have been described as *Pronophila* or *Oxeoschistus*.

M. prochyta Hew. (= *Oxeoschistus erebus* Gr.-Sm.) (57 e). Above unicolorous dark brown, only the base *prochyta*. and apical part of the forewing somewhat lighter. The ♀ has an indistinct, somewhat lighter brown costal spot and sometimes 2 reddish grey spots between the median veins of the forewing. Bolivia (Yungas de la Paz). — **chyprota** Gr.-Sm. (57 e) may probably be regarded as the Peruvian form of *prochyta*. It is somewhat *chyprota*. smaller, on the under surface quite similarly marked, only more red-brown. On the upper surface the basal part of the wings is entirely red-brown, the distal part spotted with red-brown. From Peru (Cuzco, Callanga, Vilcanota).

M. thammi Stgr. (57 e upper and under surface). Similar to the preceding species, but the hindwing *thammi*. almost entirely chestnut-red above, with 3 black spots before the margin. The under surface very variegated. Peru (Chanchamayo, Cushi, Hunancabamba).

M. poecania Hew. Forewing above unicolorous brown, hindwing brown, the anal part occupied by *poecania*. a red-brown area, which reaches to the middle of the wing and is traversed by a brown submarginal line. The under surface is quite similar to the preceding species. From Ecuador. Rare.

M. irmina Dbl. (58 a). May be known by the large white spot of the hindwing on the upper surface, *irmina*. which is otherwise dark brown. The under surface is very similar to that of *prochyta*, except that the apex of both wings is marbled with lighter grey-brown. In the ♀ the distal margin on the upperside of the hindwing is narrowly brown-red, a brown-red spot is placed before the apex and 2 indistinct spots between the median veins of the forewing. Venezuela (Merida), Colombia (Bogotá, Rio Vitaco).

50. Genus: **Proboscis** Thieme.

This genus is distinguished by having the apex of the forewing falcate and strongly recurved posteriorly. The costa of the hindwing is concave. The distal margin of this wing is dentate and forms a short tail on the 2nd median vein. Only one Colombian species, which HEWITSON made known as a *Pronophila*.

P. propylea Hew. (58 b). Forewing beneath brown, with red-brown base and apex and 3 brownish *propylea*. yellow spots before the distal margin. Hindwing beneath yellowish brown with brown median band and brown margin, in which is placed a row of whitish yellow spots and dots. Colombia. The species is very rare and was unknown to THIEME in nature. FASSL took a specimen in the neighbourhood of Muzo at 2000 m.

51. Genus: **Drucina** Btlr.

Forewing narrow and elongate, its apex less recurved than in *Proboscis* and, with the exception of *orsedice*, rounded, the distal margin weakly excised, but even, that of the hindwing slightly undulate or smooth. Palpus long and porrect, the terminal joint almost half as long as the middle joint.

leonata. **D. leonata** Btlr. (58a, b). The ♀ is somewhat larger than the ♂, of which we figure both surfaces, the apical part of the forewing above is somewhat lighter and there are some milk-white spots in the disc. On the hindwing the ferruginous stripes extend further and between them are placed beyond the cell 3 obscure white rays. Costa Rica (Irazu and Rio Sucio), Panama (Volcan de Chiriqui).

championi. **D. championi** Godm. & Salv. Somewhat larger than the preceding species. Above black-brown. Forewing with a submarginal row of 5 or 6 small ochre-yellow spots, hindwing with 6 bright blue oval spots in a curved row, of which 5 are large (5—10 mm. in length) and the last, at the anal angle, small. Forewing beneath brown with the apex marbled with grey and with 4 white spots, the hindwing marbled with grey and brown, with brown spots and indistinct double row of eye-spots. A rare and beautiful species. Discovered by CHAMPION in Guatemala (Cerro Zunti), coll. GODMAN and SALVIN.

venerata. **D. venerata** Btlr. (58 b, c). BUTLER and STAUDINGER have referred this species to the genus *Pronophila*. Although the forewing is not so sharply pointed as in the other *Drucina* species, yet the narrow, elongate forewing with its oblique distal margin seems to me to point rather to the genus *Drucina*, to which THIEME has referred it. Hence I follow this arrangement. The ♀ is distinguished from the ♂, which we figure on both surfaces, by having the light spot on the underside of the hindwing not white but brownish grey, so that it stands out but little from the ground-colour, on the other hand the dentate line before the anal angle is distinctly white. Peru, Bolivia (San Antonio and Cillutincara).

orsedice. **D. orsedice** Hew. The forewing is pointed, but the apex is not recurved. Above red-brown. Both wings with a red spot in the cell and 2 rows of red spots beyond the middle, which are small on the forewing, large on the hindwing. Hindwing further with some red marginal spots. Forewing beneath reddish, with a pale brown spot before the apex and some red spots between the median veins, on which are placed a row of 4 black eye-spots, mostly with white pupils. Hindwing beneath pale brown, a red-brown band before the middle, then a row of 5 red-brown spots with white pupils. Expanse $2\frac{1}{5}$ in. (71 mm.). Ecuador, Peru (Huanca-bamba). — **astoreth** Thieme is a form of *orsedice* in which the forewing is unicolorous brown above and the red marginal spots of the hindwing are absent. Expanse 60 mm. Bolivia (Yungas de la Paz). — **violacea** form. nov. (on pl. 58 erroneously called *orsedice*) seems to be a form near to *orsedice* or a separate species. It is characterized by the brownish violet ground-colour of both wings. All the margins and all the veins are bordered with dark brown; the costal margin of the forewing and the distal margin of the hindwing are in addition narrowly bordered with violet-brown. The submarginal spots are light-pupilled on the under surface. From Macas in Ecuador. Coll. NIEPELT.

52. Genus: **Dioriste** Thieme.

The species of this genus, which on account of their similar shape were formerly referred to *Oxeoschistus* Btlr., THIEME has separated from it, as they all have a certain resemblance *inter se*. This consists in the presence on the upper surface of large white or light yellow spots and on the underside of the hindwing of a whitish yellow discal band with a submarginal row of eye-spots.

tauropolis. **D. tauropolis** Dbl. & Hew. (= *laetifica* Bates) (58 c). May be known by the large, sharply dentate, yellowish white spot on the hindwing, which on the underside is prolonged to the inner angle as a narrow stripe and encloses a row of eye-spots; there is further a white line at the base beneath. The spots of the forewing are alike above and beneath. Distributed from Mexico over Guatemala to Nicaragua. — **cothon** Salv. is a somewhat aberrant form of *tauropolis*. It has on the forewing 3 additional whitish yellow spots (2 before the apex, 1 in the disc), the spot on the hindwing is larger and on the underside the band which crosses the cell of the hindwing is much broader and occupies a larger area of the cell. From Costa Rica and Panama.

cothonides. **D. cothonides** Gr.-Sm. (58 d). Recognizable by the broad brick-coloured red-yellow median area of the hindwing, which changes into red-brown towards the inner margin. 3 small black eye-spots with white pupils near the anal angle. The under surface is not strikingly different from that of *cothon*. The ♀ is marked quite similarly to the ♂. Costa Rica (Carthago), Panama (Chiriqui).

leucospilos. **D. leucospilos** Stgr. (58 c). Forewing above almost unicolorous dark brown; the markings of the under surface (which we figure) only show through very indistinctly. Hindwing above with large irregular white spot in the cell. Peru, Ecuador. — **pugil** Thieme (58 c) is a form in which the white spot on the upperside of the hindwing is somewhat larger and bears a round dark brown spot, in place of which on the under surface there

is added a fifth eye-spot. In the ♀ the markings of the underside are also present above and on the hindwing the white spot is prolonged to the costa. Bolivia (Illimani and Yungas de la Paz).

53. Genus: **Cheimas** *Thieme*.

Apex of the forewing rectangular, margin of the hindwing slightly undulate. Above with large, slightly glossy, yellowish or bluish white spot on the hindwing. Beneath almost without markings, red-brown. Only one species, published as *Oxeoschistus*.

Ch. opalinus *Stgr.* (58 d). The large silver-grey spot of the hindwing with variously coloured reflections, *opalinus*. According to the angle of light it has a golden yellow or a light blue sheen. The under surface is entirely red-brown with the margin but little darker. Hindwing with dark brown transverse lines, a yellow median dot and a submarginal row of yellow dots. Venezuela. — **spoliatus** *Stgr.* (58 d) is a form of *opalinus* with the *spoliatus* yellow dots on the underside of the hindwing entirely absent and the spot on the upperside less white. Likewise from Venezuela.

54. Genus: **Oxeoschistus** *Btlr.*

After the species of the preceding genera *Mygona*, *Proboscis*, *Diorista* and *Cheimas*, which BUTLER had united with *Oxeoschistus*, have been removed, this genus only contains quite similar species, which agree in the following points: Palpus thinly haired, its terminal joint pointed and projecting for about the length of the head. Apex of the forewing rounded and not distally produced. Distal margin of the hindwing more or less strongly undulate. Most of the species have on the upperside a broad brick-coloured red-yellow submarginal band which bears a row of black spots. They occur in the high mountains from Guatemala to Bolivia.

O. pronax *Hew.* (58 d). On the upperside the band is curved basewards at the costal margin of the *pronax* forewing, by which the species may be known. Beneath the forewing is as above, but the band whitish at the costal margin, the hindwing red-brown with 2 rows of yellowish white spots before the margin, which are bisected by the black veins. Between them some very small eye-spots. Peru and Bolivia.

O. duplex *Godm.* (58 d). The band is distally sharply dentate on the hindwing and at the distal *duplex* margin there is a row of red-yellow crescents. The black-brown spots on the band are very large. On the under surface the apex of the forewing is ferruginous, the band anteriorly white. Hindwing red-brown, the band bordered with white at both sides, a white line is placed in the basal area and the black spots have white pupils. Bolivia, Peru.

O. simplex *Btlr.* (58 e). The band is anteriorly narrow and posteriorly broad and at the inner margin *simplex* of the hindwing extends to the distal margin. The dark spots are scarcely half as large as in *duplex*. The figure of the under surface (pl. 58 e) represents a ♀. In the ♂ the white median stripe of the hindwing is only half as broad. — According to FASSL the egg is the same size as that of *Satyrus briseis*, is spherical and has a mother-of-pearl gloss on the surface. The species is distributed in Colombia. FASSL found it already at 1200 m., but also at altitudes of 2500 m. According to GODMAN it also occurs in Ecuador.

O. puerta *Westw.* (58 d) differs from *simplex* in that the red-yellow band decreases less in breadth *puerta* anteriorly, but on the hindwing does not extend to the distal margin. On the other hand the brown distal border reaches the anal angle. The brown spots vary in number and size. HEWITSON gives the number of spots on the forewing as 4, on the hindwing as 7, in the example figured only a few are present. Beneath the brown spots on the forewing are very small, the hindwing similar to that of *simplex*. Colombia, Venezuela, Costa Rica. — **submaculatus** *Btlr.* (58 e) is a form of *puerta* in which the red-yellow band is especially *submaculatus* broad on the hindwing and as in *simplex* extends to the anal angle, but on the forewing becomes very narrow and is anteriorly broken up into small spots. Instead of the brown spots there are on the hindwing only a few dots at the anal angle, on the forewing they are entirely absent. Beneath the proximal part of the forewing is very dark. From Costa Rica. — **pervius** *Thieme* is a similar form to *submaculatus*, but considerably *pervius* larger, with the band on the forewing broader and not broken up into spots. From the province of Cauca in Colombia.

O. isolda *Thieme* may be recognized by the dark mahogany-red band, which is the same shape as in *isolda* *puerta*, thus not touching the distal margin of the hindwing. The spots placed on this band are very small or absent, especially on the forewing. The under surface is similar to that of *puerta*, but the markings are duller, the ocelli smaller and not bordered with yellow. In the ♀ the colouring of the upper surface is somewhat lighter. Ecuador (Mirador) (HAENSCH).

- protogenia*. **O. protogenia** Hew. (59 a). The bright red-yellow band of the upper surface is especially broad on the hindwing and the row of brown spots placed in it is complete. On the underside of the hindwing the basal transverse line is absent, by which the species may be known. Colombia, Ecuador, Peru, Bolivia.
- euryphile*. **O. euryphile** Btlr. (= euriphyle) (59 a. Upper surface. The U on the plate is incorrect). May be known by the light yellow colour of the band, which on the upperside only shades off somewhat into red-yellow in its distal part, but on the underside into white, and on the forewing is entirely broken up into spots. Beneath the forewing has 4 ocelli and before the apex several white spots, the hindwing in the proximal part some light markings and distally a row of eye-spots. From Costa Rica (Irazu), Panama (Chiriqui).
- hilarus*. **O. hilarus** Bates. Instead of the band there are here on the upper surface 2 rows of small, irregularly placed red-yellow spots on both wings. On the under surface of the forewing the spots are white and some of them joined together in pairs. Between them are placed black spots bordered with red-yellow. Hindwing brown, all the veins white, 2 sulphur-yellow transverse bands cross the middle, so that a latticed pattern is formed. In addition a white dentate line is placed at the margin. Guatemala (Volcan de Fuego, Cerro Zunil, Purula), Mexico (Xantipa and Omilteme in Guerrero).

55. Gattung: **Pronophila** Westw.

In consequence of the division proposed by BUTLER only a few out of the large number of *Pronophila* species figured and described by WESTWOOD, HEWITSON, FELDER and others are still regarded as belonging in this genus, and indeed only those which are similar in shape and markings to the first two species cited by WESTWOOD (*thelebe* and *cordillera*). The greater part of the others form the present genus *Pedaliodes* Btlr. (p. 250). The *Pronophila* species (in the restricted sense) have broad wings, the hindwing nearly round with the distal margin more or less undulate, the inner margin of the forewing comparatively long, its distal margin consequently vertical (not oblique) and nearly straight. On the underside of the forewing almost all bear a row of black eye-spots with blue pupils; the upper surface is black-brown, sometimes unicolorous, sometimes with white, brownish red or grey-brown spots before the apex of the forewing. They are mostly rather large butterflies, and inhabit the high Andes from Central America to Bolivia.

- timanthus*. **P. timanthus** Salv. (59 a upper and under surface). The black spots, which on the upperside are placed on the long brownish red oval patches, bear on the under surface blue pupils. Costa Rica (Irazu), Panama (Chiriqui). — **intercidona** Thieme (59 a) may perhaps be regarded as a form of *timanthus* in which the proximal halves of the oval patches are wanting with the exception of the anterior ones and which has these spots brilliant golden brown. Sometimes there is further a red spot between the 2nd and 3rd median veins. From Ecuador (Santa Inez).
- deverra*. **P. deverra** Thieme has before the distal margin of the forewing a row of light reddish spots, the anterior ones somewhat larger. The under surface resembles that of *Pron. thelebe* (59 b), especially the hindwing. On the forewing the macular band is continued further, to the inner margin, and is not white, but has the light reddish brown colour of the upper surface. From Ecuador.
- assarhaddon*. **P. assarhaddon** Thieme (= *rosenbergi* Lathy) (59 b). Above black-brown, at the base somewhat lighter, the forewing with the same white macular band as on the figured under surface. Hindwing only with the tips of the fringes between the veins white. Ecuador (Santa Lucia) (HAENSCH).
- thelebe*. **P. thelebe** Dbl. & Hew. (59 b) is the best known species of the genus. The white spots on the upper surface vary in number, size and shape. Examples from Peru and Bolivia are more copiously spotted with white than those from more northerly localities. The ♀ has the ground-colour of the upperside much paler brown and the hindwing is more strongly dentate. Venezuela, Colombia, Ecuador, Peru, Bolivia. — *obscura*. **obscura** Btlr. is probably a *thelebe* form. According to BUTLER's description the colouring of the upper surface is as in *thelebe*. Hence we must assume that the upperside has white spots on the forewing. But the under surface, which BUTLER figures, shows no such spots, only the apex is whitish. The 4 black eye-spots with light blue pupils are placed in the disc in a straight row on a dark ground. The underside of the hindwing is almost exactly like our figure of *thelebe*, pl. 59 b. Venezuela. 2 examples in the Brit. Museum.
- thelebina*. **thelebina** Thieme (59 b) is a further form of *thelebe*, somewhat smaller and with smaller white spots, only the first is the same length as in *thelebe* and bears above a black dot at its proximal end. The hindwing is smooth-margined. On the under surface the ocelli and the red dots are indistinct, as also are the markings on the hindwing. Colombia (Rio Dagua), Peru (Chanchamayo), Bolivia (Yungas de la Paz).
- brennus*. **P. brennus** Thieme (59 c upper and under surface). The row of pale brown spots on the upper surface is sometimes dirty white or reddish; sometimes there is also a further small red-yellow spot at the proximal side of the first of these spots. In the ♀ the ground-colour is not so deep black as in the ♂, hence the row of eye-spots on the under surface is sometimes visible in the ♀ on the upperside also, as was the case in one of the examples found by FASSL. Hitherto only found in western Colombia, in the Cauca Valley by HAHNEL, Popayan and Rio Dagua by KALBREYER, Rio Agna Valley by FASSL.

P. orchus Hew. (= *orcus* Btlr.) (59 c). Above dark brown with four small grey spots before the apex *orchus*. of the forewing. On the under surface the species may be known by having several white spots before the apex and a red-yellow one in the middle of the forewing and at the anal angle of the hindwing a fine black dentate line on a white ground. Colombia.

P. cordillera Westw. (59 c). Above brown, hindwing and apex of the forewing with slight reddish *cordillera*. brown gloss. This beautiful species may be recognized by the chestnut-red basal half of the forewing beneath. Bolivia.

P. orcus Latr. (= *orchamus* Godt., *porsenna* Hew.) (60 a). Above unicolorous dark brown, only the apex *orcus*. of the forewing somewhat lighter. The distal margin of the hindwing is weakly undulate. The ♀ is somewhat larger (expanse 78 mm.) and somewhat lighter brown and has on the upperside of the forewing 4 round black spots, corresponding in position to the eye-spots of the under surface. These spots are placed in a yellowish brown patch. Instead of the grey-brown colour of the ♂ the ♀ has the ground-colour of the underside of the hindwing light reddish brown, as also the distal margin of the forewing. The dark markings are all of a dark red-brown colour. Colombia. FASSL took both sexes at the Alto de los Anees at an altitude of 2200 m. and at the Quindiu Pass (2600 m.). — **locuples** Thieme is a form of *orcus* in which the under surface of the *locuples*. forewing bears a second small red-yellow spot near the costa. On the upper surface the lighter brown apical shade is separated by a brown border from the distal margin. Bolivia. — **nepete** Thieme is a further *nepete*. form which has on the upper surface a light yellow-brown macular band with slight golden gloss, extending from the costa to the 2nd median and also marked on the underside as a brownish white area. Otherwise the under surface does not differ from that of *orcus*. From Peru (Chanchamayo). — A third form is **parallela** Thieme. In it the 4 ocelli on the forewing beneath are placed in a straight line one below another, *parallela*. parallel with the distal margin, and all of uniform size, and the last but one is bordered with red at both sides. From Venezuela (Valencia).

P. variabilis Btlr. is allied to *orcus* Latr. (*porsenna* Hew.). Above with green and reddish bronzy *variabilis*. gloss, without white spots, but with 3 dark spots at the apex of the forewing and 2 or 3 at the anal angle of the hindwing. Beneath the red-yellow spot of the forewing is absent, the hindwing is more whitish, the bands at the base and in the middle darker, with 8 white-pupilled and light-bordered eye-spots and a broad brown margin, proximally bordered with lilac. Peru.

P. epidipnis Thieme (60 a). Above unicolorous brown. Beneath similar to *orchus* Hew., but the ground- *epidipnis*. colour of the hindwing is throughout light grey without white, only at certain angles a slight silvery gloss is visible. The median band is nearly straight. Merida, Venezuela.

P. lucomo Thieme. A large species. The costal margin of the forewing is somewhat longer, hence the *lucomo*. distal margin is more oblique than in the other species. Hindwing strongly dentate, its distal margin somewhat produced in the middle. Above dark brown, before the apex somewhat lighter. Beneath similar to *orchus* Hew., but without the red-yellow spot on the forewing. On the hindwing the dark median band is bordered with white on both sides at the costal margin; at the inner margin a large white spot is placed before it. From Vilcanota in Peru. Coll. STAUDINGER in the Berlin Museum.

P. colocasia Thieme is similar to the preceding species, unicolorous brown above, and differing from *colocasia*. it in having the median band of the hindwing beneath broader, sharply defined on a silvery ground, basally bent round and not reaching the inner margin. The anterior part of the distal margin of this wing is broadly bordered with ferruginous. From Rioja in Peru. Coll. STAUDINGER in the Berlin Museum.

56. Genus: **Corades** Dbl. & Hew.

The species of this genus may be known at a glance by the elongate form of the hindwing, the anal margin of which runs out in an almost straight line into a long tail, which is formed by the first median vein. Consequently the cellules at the inner margin are very narrow. Only in a few species the tail is shorter. The distal margin of the forewing is plain or rounded, that of the hindwing likewise plain or slightly undulate. The costal vein of the forewing is swollen at the base. Two subcostal veins arise before the end of the cell on the forewing. The middle discocellular forms on both wings an angle proximad, from which arises a small recurrent vein. The rather long palpi and the eyes are finely haired. The butterflies are of medium size, the upper surface unicolorous black-brown or partly red-brown or yellow-brown, sometimes with yellow or white spots. The under surface is often light and dark marbled, the hindwing then agreeing in colouring with the apex of the forewing. Sometimes silvery stripes are present. Their range of distribution embraces the Andes from Venezuela to Bolivia, only one species reaches North Argentina. Statements differ as to the vertical distribution. The altitude at which the *Corades* species fly is given by BÜRGER in his „Reisen eines Naturforschers“ as 500 m. to 2800 m., whilst according to THIEME they are confined to particularly high altitudes and FASSL gives the lowest elevation as 1400 m., the highest as over 3500 m. They always fly singly and are not common.

C. pannonia Hew. (= *ichthya* H.-Schäff., ♀ = *fluminalis* Btlr.). Above unicolorous brown. Forewing *pannonia*.

- beneath brown with silvery striation at the apex and 3 red spots in the disc. Hindwing beneath striated with silver throughout, with a broad yellow band across the middle. *fluminalis* Btlr. may probably be regarded as the ♀ of *pannonia*. Upper surface brown with 2 white spots at the costa and 3 red-yellow ones between or beside the median veins. Hindwing with 3 ferruginous streaks between the veins. Beneath the forewing has paler spots. Hindwing ochre-yellow striated with copper-brown and with copper-brown median and marginal bands. Venezuela. BUTLER does not give the locality of his *fluminalis*. — *ploas* Thieme (59 d) is the Colombian form of *pannonia*. In it the 3 red-brown spots on the underside of the forewing are much darkened and scarcely visible, the hindwing has instead of the broad yellow band a silvery grey one, which, however, is largely covered with brown striation. The ♀ was found by FASSL and differs from the ♂ in having 2 small brownish white spots on the brown upper surface, placed at the costal margin, one 9, the other 17 mm. from the apex, the latter bipartite. Apex and distal margin broadly lighter. The under surface is coloured like that of the ♂, except that the white colour is somewhat more extended. A second form of the ♀ (*domina* form. nov.) (59 d), in addition to the 2 somewhat more distinct white spots, has on the upperside of the forewing a row of 4 red-yellow spots and on the hindwing a row of red-brown ones, and below them a red-brown stripe which runs to before the tip of the tail. The distal margin is also narrowly bordered with red-brown. The under surface is as in the first female form. Colombia (Alto de las Cruces), 2400 m., West Cordillera. According to FASSL the egg of *ploas* is somewhat larger than that of *Pap. machaon*, bomb-shaped, bone-white, smooth at the base, otherwise much pitted.
- argentata*. **C. argentata** Btlr. (= *pannonia* Hew. part.) (59 d). Above brown, distally lighter. Forewing beneath with 3 golden brown spots. Hindwing beneath with dark basal and median areas, anteriorly separated by a short silver line and distally bordered by a somewhat curved one. Bolivia.
- melania*. **C. melania** Stgr. The tails are somewhat shorter, the upper surface unicolorous glossy bronze-brown. Under surface dark brown, forewing with a small whitish spot between the first and second median veins, which is sometimes absent. The hindwing is entirely covered with fine, short, silvery transverse streaks, so that the dark median band can scarcely be recognized. Bolivia.
- cybele*. **C. cybele** Btlr. (60 b). Above unicolorous black-brown. Beneath the species may be known by the golden brown hammer-shaped spot on the forewing. Colombia. — *semitiplena* Thieme is a form with the posterior half of the cell on the forewing beneath filled up with golden brown along the median. Peru. — *fusciplaga*. **C. fusciplaga** Btlr. is probably a further form of *cybele*; the underside of the forewing bears a very small light brown spot in place of the golden brown hammer-shaped spot. According to BUTLER the upper surface is similar to that of *sareba*. Peru.
- medeba*. **C. medeba** Hew. (60 a) has shorter tails and in the ♂ a unicolorous brown upper surface. On the under surface recognizable by the red-yellow longitudinal stripe in the cell of the forewing and some red-yellow spots behind it in the disc. The ♀ has on the upperside a row of small, obscure reddish spots on the forewing and also some similar spots in the disc of the hindwing. From Colombia to Bolivia. — *columbina*. **C. columbina** Stgr. (60 b) is a *medeba* form in which there is only a small spot in place of the red-yellow longitudinal stripe on the under surface. Occurs not only in Colombia but also in Bolivia among the type-form.
- sareba*. **C. sareba** Hew. (= *melusina* Stgr. i. l.) (60 b) may be known by the brownish yellow basal half of the forewing beneath. Upper surface dark brown, the forewing with an indistinct submarginal row of somewhat lighter spots. Bolivia.
- chirone*. **C. chirone** Hew. (♀ = *laminata* Btlr.) (♂ 60 a under surface, on the plate erroneously called *ulema*, ♀ 59 d upper surface). The ♂ is unicolorous brown above. Beneath differing from *ulema* in having in the posterior half of the forewing only 2 light yellow spots, not 3 as in *ulema*, and in the light band on the hindwing between the base and the middle only reaching the median, whilst in *ulema* it extends nearly to the base of the tail. The ♀ (*laminata* Btlr.) has on the upperside of the forewing a submarginal row of yellow-brown spots, which in the anterior part of the hindwing are united into a broader half-band. Beneath the markings are similar to those of the ♂, which we figure, but at the inner angle of the forewing there are 3 larger, ochre-yellow spots in place of the 2 in the ♂. The hindwing is marbled with lighter in the basal and median areas and instead of the ochre-yellow stripe in the middle of the silver-white band there is here a brown and white marbled stripe. Both sexes of this species, which is at present in but few collections, were found by FASSL in July on Monte Socorro (Colombia) at an altitude of 3500 m.
- ulema*. **C. ulema** Hew. (59 d under surface, erroneously called *chirone* ♂ on the plate). According to HEWITSON the upper surface is unicolorous brown, the example figured here is likewise brown, but has a red-brown gloss throughout, with no trace of a band. The examples with distinct light submarginal band, mentioned by THIEME, are thus transitional to the form *tripunctata*. Beneath similar to *chirone*, the differences have been given above under the latter. The ♀ has on the upperside a submarginal row of red-brown spots on the forewing, a narrow, continuous red-brown band on the hindwing. On the under surface 4 red-yellow spots are placed in the posterior part of the forewing, on the hindwing the first band is anteriorly white, posteriorly sprinkled with brown scales, hence indistinct, the outer band is light ochre-yellow, basally margined with white, *tripunctata*, and contains 3 fine black dots. From Bolivia and Peru (Huancabamba, Limbani). — *tripunctata* Weym.

is a form of *ulema* Hew. in the male of which a row of brownish red-yellow spots runs from the costal to the inner margin on the forewing above and is continued to the inner angle of the hindwing as a continuous band, anteriorly broad, posteriorly tapering to a point. 3 small round black spots are placed on this band in the anterior part of the hindwing. The under surface is similar to that of *ulema*, but the bands are broader and much purer white. Peru (Puente de Sigsi in the valley of the Rio Sonchi, 2500 m., June [STUBEL]).

C. albomaculata Stgr. (60 a). May be known by the dull white, bi- or tripartite apical spot on the upperside of the forewing. Beneath similar to *plous*. The ♀ is somewhat larger than the ♂ and has an additional small white spot on the costa. Beneath the apex and the distal margin of the forewing are more strongly marked with silver-white than in the ♂. Bolivia and North Peru. *albomaculata*.

C. cistene Hew. (60 b). Above brown with 6 small golden brown spots in a very sinuous row on the forewing and indistinct spots on the hindwing, which scarcely stand out from the ground-colour. Beneath the species may be recognized by the unusual shape of the brown median band on the hindwing (cf. fig.). Bolivia. — **dymantis** Thieme (= *callipolis* Stgr.) is a form of *cistene* in which 2 or 3 small golden brown spots are present also on the upperside of the hindwing. Venezuela, Colombia and Ecuador. — In the form **generosa** Thieme (= *peruviana* Stgr.) (60 b) the golden brown spots on the upperside of the forewing are larger and across the hindwing runs a half-band composed of contiguous golden brown spots. Peru. *cistene*, *dymantis*, *generosa*.

C. enyo Hew. (= *auriga* H.-Schäff.) (60 c) is characterized by having the upper surface of the hindwing almost entirely golden brown, which colour also extends to the base of the forewing. The under surface is similar in markings to that of *almo* (cf. figure, pl. 60 c), but the apex of the forewing and the entire hindwing are light whitish grey and the 2 median stripes of the hindwing quite narrowly brown and distally bordered with white. From the mountains of Caracas, Venezuela. This form is for the most part only represented in older collections. The Colombian form more recently incorrectly distributed in collections under the name *enyō* is much darker and should be called **almo** Thieme (60 c). The hindwing is dark brown above, distally chestnut-colour, beneath marbled with dark grey-brown. The ♀, which is likewise figured, has on the hindwing a golden brown submarginal band and on the under surface of both wings the greater part of the distal margin broadly golden brown. Colombia, Ecuador, Peru, Bolivia. *enyō*, *almo*.

C. chelonis Hew. (60 d). Similar to the preceding, but the forewing bears only 3 larger spots. Beneath the 2 apical spots are white. In the ♀ these apical spots are contiguous above and the posterior spot, between the median veins, is three times as large as in the ♂. Colombia (Quindiu Pass and Cañon del Tolima, 2500 m.) (FASSEL). — **rubeta** Thieme, a form of *chelonis*, has the hindwing more rounded and the tails shorter, forewing somewhat broader, sometimes with a small fourth golden brown spot at the inner margin. From Merida in Venezuela. — The form **lactefusa** Thieme has the under surface of the forewing entirely milk-white, only a thin brown line crosses the middle of the wing. Ecuador. *chelonis*, *rubeta*, *lactefusa*.

C. iduna Hew. (60 d, erroneously as *marginalis*). Resembles *chelonis* in the forewing, but the 3 spots are white, not golden brown. In the anterior part of the hindwing there is a large, bright red-yellow or golden brown spot, which does not reach the distal margin. Bolivia. — In the form **marginalis** Btlr. (= *marginata* Kirby) the golden brown discal spot reaches the distal margin. Peru (Huancabamba and Cushi). *iduna*, *marginalis*.

C. peruviana Btlr. (60 d) was formerly regarded as a variety of *iduna*. According to THIEME it is a separate species. The white spot between the median veins of the forewing is not bipartite as in *iduna*, but consists only of one spot between the first and second medians. The anal angle of the hindwing is more produced than in *iduna* and the disc almost entirely bright reddish golden brown. The distal margin is only narrowly, the inner margin broadly dark brown. From Ecuador and the coast Cordilleras of Colombia. *peruviana*.

C. procellaria Thieme is the smallest species of the genus and resembles *iduna*, but the forewing is shorter, the hindwing more rounded and the tail much shorter. The white spot between the median veins of the forewing is bipartite as in *iduna*. The 2 white apical spots as in that species. Hindwing dark brown with a ferruginous submarginal spot in the apex, which is posteriorly lost in the ground-colour. From the Aconquija Mountains near Tucuman, North Argentina. *procellaria*.

57. Genus: **Panarche** Thieme.

This genus may be regarded as a connecting link between *Corades* and *Polymastus*. As in *Corades*, the first median vein of the hindwing runs out into a long projecting point and the inner margin of this wing is as straight as in that genus. On the other hand it differs widely from *Corades* in the straight costal and angled distal margin of the forewing and the sharp, pointed teeth of the hindwing, in which respects it approximates more to *Polymastus*. It is, however, easily distinguished by the triangular hindwing, produced into a point at the inner angle, the species of *Polymastus* having the hindwing shorter and broader, with the inner margin rounded. The costal of the forewing is only slightly swollen. The 3 species are rare and are indigenous to the high mountains of Bolivia and Peru.

tricordatus.

P. tricordatus Hew. (Corades t.). Forewing with 2 fine points in the anterior part of the distal margin, its posterior part obtusely dentate; anterior part of the hindwing also obtusely dentate, only the 3 median veins having long points, that of the first median projecting furthest. Above brown, distally lighter, the margins dark brown, forewing with white costal spot, hindwing with a submarginal row of black spots. Forewing beneath red-brown, striated with light yellow, the forewing at apex and the hindwing dark brown with white striation. The latter with several white spots, black margin and black submarginal band. From Mapiri and the Illimani, Bolivia.

callipolis.

P. callipolis Hew. (Corades c.) (60 d). The teeth of the distal margin are not so pointed as in *tricordatus*. Above brown with dark margin. Forewing with a lighter brown submarginal band, proximally bordered by a dark brown dentate stripe, similar to that shown in the figure of the under surface in the middle of the forewing. From Bolivia (Illimani). For *callipolis* Stgr. cf. supra, p. 275, under *C. dymantis*.

anfortas.

P. anfortas Thieme is larger than *callipolis*, the teeth of the hindwing longer. The ground-colour of the upper surface is cedar-wood brown. Basal area and distal margin of both wings dark brown. Beyond the middle of the wing is placed a row of dark brown spots, on the forewing elongate, on the hindwing round. In addition on the forewing 2 elongate spots in the cell and 2 round ones before the apex. Forewing beneath brown with silvery brown submarginal macular band, its proximal edge dentate. Hindwing beneath with brown discal band, before this a silvery half-band and distally a partly silvery, partly brown-dusted submarginal band. From Cuzco in Peru. Rare.

58. Genus: **Bia** Hübner.

An isolated genus, possessing various peculiarities. Palpus moderately long, thinly haired, the terminal joint thin and pointed. Eyes naked. Forewing with the costal and distal margins rounded. Hindwing produced at the inner angle into a point which projects far posteriorly and is placed on the first median vein. In the forewing the costal vein is strongly inflated at the base, the median and submedian less swollen. The cell of the forewing is longer at its posterior than at its anterior margin. On the hindwing there are two hair-tufts (scent-organs) in the ♂♂. One is placed in the inner-marginal fold and is composed of ochre-yellow hairs about 3 mm. in length, which may be erect and diverging or again convergent. The other, at the anterior margin of the cell, consists of short, erect, dark brown scales, which are partly covered by long, smoothly appressed, lighter brown and yellowish grey hairs. Inhabits Surinam and the whole Amazon region as far as Peru.

actorion.

B. actorion L. (60 e). The bright iridescent blue spot at the inner margin of the forewing in the ♂♂ varies in size, in single examples from the Upper Amazon it occupies almost the whole distal margin, in others it is very small or entirely disappears. In the ♀ on the other hand the whole basal half of the forewing nearly to the costal margin is bright iridescent blue. Under surface red-brown, densely covered almost all over with fine light brown or yellowish brown undulate lines. Below the apex of the forewing close to the distal margin is placed a small black ocellus with blue pupil. From Cayenne, Para and the whole Amazon region. The form **decaerulea** Stgr. i. l. (60 e) shows no trace of blue reflection, on the other hand the brownish yellow band is somewhat broader. It occurs among the type-form. — **atalanta** Rebel (60 e), on the contrary, has on the hindwing a very bright dark blue reflection, occupying nearly all the posterior half of the wing. The forewing is without reflection and the brownish yellow band is very narrow. The under surface as in *actorion*. Peru.

decaerulea.*atalanta*.

Additions and Corrections

to the American *Satyridae*.

theodori.

P. 182. **Antirrhaea theodori** Fruhst. is a form of *philaretus* only described in the female, in which, instead of the 4 blue spots which *philaretus* ♀ has on the upperside of the hindwing, only 2 are present, and these are pale grey. The under surface is exactly as in *philaretus*. From the Upper Waupes (North Brazil). — **A.**

apoxyomenes.

apoxyomenes Fruhst. approaches *avernus* Hpffr., but is larger, with broader yellow-white bands on the forewing and more extended blue spotting on the hindwing. Bolivia.

P. 183. *Sinarista adoptiva* Weym. The ♀ of this species has been found by FASSL likewise in the Colombian West Cordilleras, in the Rio Aguaca Valley, at 2000 m. It is but little larger than the ♂, but, like the ♀♀ of *Ant. geryon* and *geryonides*, has broader wings, so that the apex of the hindwing is obtusely rectangular. The point of the tail directed more distally. The ground-colour is somewhat lighter brown, the eye-spots of the forewing are larger, have thicker white pupils and are bordered by obscure red-brown rings. At the costal margin there is further a fourth, small, pupilled ocellus. The under surface is red-brown with a broad band, striated with dark brown, across the middle of both wings. In the distal area 4 white dots on the forewing and one on the hindwing.

protonoë.

In *Caerois chorinaeus* F. the ♀ is about 3 cm. larger than the ♂. — **protonoë** Fruhst. is a form of

chorinaeus in which the male also is larger than the type-form and much darker both above and beneath. Peru.

P. 184. **Tisiphone hyrnethia** *Fruhst.* (Manataria hereina h.), a form of *hercyna*, has the whitish yellow *hyrnethia*. macular band of the forewing so much widened that it occupies nearly a third of the wing and covers the anterior half of the cell. The under surface is lighter than in the type-form and has the white spots more than twice as broad and only in part isolated. Peru and Bolivia.

P. 188. **Taygetis weymeri** *Draudt* should be inserted before *andromeda*, with which the shape of the *weymeri*. hindwing agrees, while the shorter forewing is shaped like that of *sosis* *Hpffr.* Above olive-brown. Forewing with an indistinct brown stripe beyond the middle and both wings with a dark brown distal border 2½ mm. in breadth, before the distal margin a white line, the fringes long, whitish grey with brown dots at the extremities of the veins. The under surface resembles that of *keneza* and *uncinata*, but the dark band before the middle of both wings is scarcely indicated, and the band behind the middle has no sharp angles. The eye-spots are scarcely perceptible on the forewing, on the hindwing they are distinct but very small and mostly free, while in *keneza* they are all placed on brown spots. But the species is easy to recognize by the non-angled forewing. From Guerrero, West Mexico. Flies in August and September.

5. Family: Brassolidæ.

The genera of this subdivision of the Nymphalids *sens. lat.* belong exclusively to the Neotropical faunistic region. Representatives of the family are entirely absent in the Ethiopian Region, on the other hand they stand in surprisingly close relationship to the Indo-Australian Amathusiids, which were formerly called "Morphids of the Old World", but would be more correctly regarded as "Brassolids of the Old World". Indeed Amathusiids and Brassolids have so much in common that it will probably be only a question of time to see them united, and like their Indian allies their extremes in one direction approach the Satyrids (*Opoptera*), while others form a transition to the Nymphalids (*Narope*). — In the anatomy of the clasping-organs they are much more closely allied to the Satyrids than to the Neotropical Morphids, with which they were formerly united. Especially suggestive of the Satyrids are the slender, dentate valve and the pointed uncus (*Opsiophanes*) with its delicate lateral clasps, though the uncus of one genus (*Dynastor*) rather recalls the Morphids. But whatever we adduce by way of comparison we find the characters fluctuating; thus also the strongly developed precostal, to which Dr. SCHATZ attached so much importance, the beginning of which we find again in the Morphids and which on the other hand in the Brassolid genus *Caligo* begins to disappear. At the same time the Brassolids can be definitely separated from the Morphids by having the cell of the hindwing closed, in which they also differ from the Amathusiids, where the discocellular is only exceptionally present or is only rudimentary.

The relations of the Brassolids to the neighbouring families are of different kinds. From the Nymphalids in the restricted sense, which the antennae and the neurulation of the forewing suggest, they are separated by the ocellated markings on the under surface, by the palpi, and before all by the quite different larvae, which bring them nearer to the Satyrids. From *Morpho*, with which they were formerly united, they differ especially in the elongate, naked larva, which lives on Monocotyledons, and bears no resemblance to the short, woolly, Dicotyledon-feeding larvae of *Morpho*. From the Satyrids, which they approach in the shape of the larvae, the Brassolids are separated chiefly by the gigantic size (*Caligo*), the thickness of the body (*Brassolis*) and the structure of REUTER's "basalfleck"; in addition the veins of the forewing are not inflated at the base.

All the Brassolids agree in the brilliant eye-spots on the finely striated under surface, which are most strongly developed in *Caligo*. Only in the genus *Narope* is this character indistinct, the eye-spots being entirely absent or reduced to dots.

With the exception of one genus (*Narope*) the Brassolids embrace almost exclusively species which are either above medium size or even furnish us with the giants among the South American butterflies.

The colouring is as a rule dull, uniform and blurred, not rarely with blue and blue-green iridescent gloss; only a few species are brightly and sharply marked, while none have a very elaborate pattern. Nevertheless some species of the genus *Caligo* are among the most sought-after show specimens in collections, and the sight of a wonderful blue-tinged *Caligo beltrao* or of the amethyst-coloured *Caligo atreus* with its yellow ornamental bands is one of the most beautiful memories of a tropical traveller. They form a characteristic of the landscape when the sun-loving *Morpho* have long ceased their flight and as harbingers of the night they leave their hiding-places and take up their posts like isolated sentries at the edge of the evergreen forest. Even more than the Amathusiids the Brassolids prefer the dusk of the moist, hot primeval forest; only a few *Opsiophanes* occasionally even in the middle of the day are attracted by the so-called "Waldschenken" in the dry underwood (Capoeira) where they enjoy themselves at the sap flowing out of the bushes.

One genus (*Dasyophthalma*) can best be compared with Indian *Elymnias* or *Zeuxidia*, as its members make their appearance in the early hours of the day, fly up and down unsteadily several times, turning their iridescent blue or greenish upper surface for a moment to the spectator, but then again disappear slowly and mysteriously in the forest-gloom. They have also in common with the *Zeuxidia* a preference for over-ripe bananas, with which they can be baited in large numbers. They then sit in a living mass in company with *Caligo beltrao* or *Eryphanis reevesi* round the suspended fruit, mostly underneath it, with the wings closed, turning the ocelli to the spectator. When anyone approaches they begin to flap their wings restlessly, before taking to flight. Even the *Caligo* species, in spite of their great size, are difficult to detect in their day hiding-places when, accidentally startled up, they settle quite near the ground, concealing themselves either on it or on tree-trunks, as the peculiarly irrorated and reticulated under surface, readily fitting in and harmonizing with the aspect of the trunk, affords them complete protection in spite of their large "owl-eyes".

Like all true forest species the Brassolids scarcely ascend above the actual zone of the densest vegetation. The species of *Caligo* and their nearest allies never exceed elevations of 1000 m. In their geographical range they agree entirely with the Morphids, not extending northwards beyond Mexico nor southwards beyond Rio Grande do Sul and Paraguay. Their headquarters are the eastern slopes of the Andes, especially the

region of the source of the Amazon and also Colombia, from whence alone 30 species are known, thus only four less than from the whole of Brazil. Ecuador again has 28, Guiana 16, Central America 17 species.

The egg of the Brassolids is spherical, more or less sharply ribbed, occasionally somewhat flattened above and beneath (*Eryphanis*). Round the greatest circumference runs sometimes a narrow red-brown stripe.

Larva so far as known gregarious when young, afterwards often solitary, sometimes in common nests on bananas, palms and other higher Monocotyledonae. Some occur in a brown and a green form (GOLLMAR), others differ in colour according to their age. In repose they mostly rest at full length between or under the gigantic leaves of the food-plant, concealed by day. The head is rather flat, broadest beneath, and is kept closely appressed to the support, the mouth being directed forward. The head bears at the upper margin of the face some spines which when at rest are inclined posteriorly and a dense covering of hairs ("poodle-head"). Along the dorsum run longitudinal lines recalling those of the Satyrids; sometimes there are very fine, quite short hairs, often small tubercles and in *Caligo* simple, spinous points and isolated setae. The pupa thick, stout, short, angular, anteriorly convex, cremaster very thick, fastened firmly and broadly to the food-plant, so that the pupa can only be detached with difficulty. Only one moveable segment. In *Narope* the abdominal part of the pupa is compressed on the ventral surface and the dorsum bears some protuberances. The colour of the pupa is at first green, afterwards earth-grey or brownish. The pupa of *Brassolis*, which remains in the nests, is Bombycid in form and differs considerably from the other genera.

The scent-organs of the ♂♂ consist of pads or mealy spots on the underside of the forewing, hair-pencils in the folded hindmargin, bristles or hair-tufts at various places on the upperside of the hindwing, often larger pencils in the cell; the latter are sometimes imbedded in pockets formed of the wing-membrane and are eversible and expansible in a stellate form. Head and body robust, the latter as in the Hestias and Morphids small in comparison to the wings. Eye large, convex, naked or hairy; the three-jointed palpus in most cases extends beyond the head, is densely scaled and varies in the degree of hairiness. Beneath the palpus frequently bears dense, shaggy hair, the 2nd joint sometimes with hair-tufts. The "Basalfleck" of REUTER covering $\frac{1}{2}$ — $\frac{2}{3}$ of the basal joint on the inner side, oval, at the distal end rounded, the swelling in *Opsiphanes* recalling that of *Discophora*, occupying almost the entire basal spot, sometimes with larger, sometimes with smaller rounder scales; these are densely placed, parallel and erect. At the distal end of the Basalfleck there are often grooves which are covered by the cones and scales.

Like the Indian Amathusiids and the Neotropical Morphids the Brassolids are also very susceptible to climatic and local influences; they show a series of gradations on the Amazon from its lower to its upper course and nearly every Brazilian province has its own *Opsiphanes* race, a circumstance to which the author of these lines first called attention. Seasonal forms, however, have not yet been detected with certainty; this is connected with the time of appearance of the butterflies, which in general have a short period, beginning with the spring of the southern hemisphere and ending in the middle of the summer. We have only certain knowledge as regards southern Brazil, but it is probable that in the true tropics some species produce a succession of generations. If VON BÖNNINGHAUSEN is correct the Brassolids split up into two unequal groups: namely those without a forked tail in the larva (only two genera, *Brassolis* and *Penetes*) and those with tailed larva (all the rest).

The originals of the figures, like those of the following family (the Morphids), are from the FRUHSTORFER collection at Geneva (Florissant). Some descriptions have been taken from the well-known work „Das Tierreich“ of the Academy of Sciences (Director, Prof. SEITZ) by kind permission of Herr STICHEL, who was the first to work out fully the family of the Brassolids.

I. Subfamily: **Brassolininae.**

Larva without tail-fork and without horns on the head.

1. Genus: **Brassolis** F.

This genus, from which the family is named, differs the most widely of any from the normal Brassolid habitus. This is seen chiefly in the compact, robust build, the thick body almost recalling the Heterocera, strong, broad head with quite short palpus, elongate, anteriorly truncate antennal club, such as otherwise occurs only in *Dynastor*, broad and hard thorax and very thick abdomen.

The few species which belong here are medium-sized, powerful butterflies with dark-coloured wings traversed by an orange band, the distal margin slightly concave in the ♂, convex in the ♀. The uncus according to GODMAN a simple hook, without lateral appendages; valve short, compact, at the distal, dorsal end slightly dentate. Egg spherical, with shallow, sometimes anastomosing longitudinal ribs of somewhat irregular course. Larva cylindrical, thickest in the middle, head without processes, beneath broad, strongly hairy. Anal points wanting, instead of them there are posteriorly 2 wart-like processes. They live gregariously, often in hundreds in large, bag-like nests on palms; the pupa is short and stout, without strong angles or protuberances, suspended by the cremaster.

B. sophorae, originally described from Guiana, from whence LINNÉ obtained his name-type, splits up into four known local forms, which are distributed on the Atlantic side to Rio Grande do Sul, on the Pacific certainly as far as Peru. All agree in bearing a broad, obliquely placed, ochreous longitudinal band on the forewing and a submarginal band on the hindwing, in the ♂ continuous, in the ♀ more indistinct and broken up into separate patches. Under surface lighter, the ferruginous spot in the basal part of the cell more distinct; cell-band in the ♀ breaking up into spots. Hindwing without distal-marginal band, dotted and striated with whitish, in the ♂ with ferruginous spot in the basal part of the cell; forewing with a subapical ocellus, hindwing with a larger ocellus below the costa and another between the lower median veins. — Larva thickest in the middle, head large and without thorns or spines, short dorsal hairs arranged in tufts, without tail-points, but with small excrescences. On palms, in nests of thick silk placed at the base of the fronds or right at the end of the stem under the covering of the palm, concealed by day. Pupa smooth, brown, suspended. — **sophorae** *sophorae*. *L.* (62 a) differs considerably in the male from the ♀, which we figure, in the peculiar shape of the wing, especially in having the costal margin of the forewing even more concave than in *astyra* (62 a). Hindwing anally narrowed, produced into an obtuse point. Rather common everywhere and in the evening from about 5 o'clock buzzing round the banana thickets near human settlements after the manner of the Sphingids. — In **lurida** *lurida* *Stich.*, from Colombia, the ground-colour is duller, the band of the forewing lighter, in the ♂ posteriorly narrowed, and ending in a point at the hindmargin. Band of the hindwing nearer to the end of the cell, running out along the lower median vein. On the underside of the hindwing there is a third eye-spot between the upper and middle median veins. — **vulpeculus** *Stich.* Body anteriorly and posteriorly fox-red. Wings paler than in *vulpeculus*. typical *sophorae*, the band of the hindwing tinged with reddish at the costal margin and posteriorly, in the cell somewhat broader, then of uniform breadth to the inner margin. The cell also tinged with fox-colour in its basal part, so that the dark median spot stands out sharply; the median also faintly dusted with reddish. In the apical part 3 small white spots. On the hindwing the ochreous band before the distal margin is considerably broader than in typical *sophorae*. Paraguay, Argentina. According to 2 examples in coll. FRUHSTORFER, the hitherto unknown ♀ has the cell of the forewing also basally somewhat more broadly and paler ochre-yellow, the band of the hindwing broader, but weaker. Underside of the forewing with the longitudinal band considerably reduced; hindwing more delicately irrorated and as is typical of Paraguay butterflies, pale earth-coloured, lighter than in examples from more northerly localities. — **ardens** *Stich.*, from Ecuador and southern Peru and probably also occurring in Bolivia, has the forewing in the ♂ 40—43, in the ♀ 49 mm in length. Band of the hindwing bright reddish ochreous, in the region of the hinder angle suffused with fiery red-brown. *ardens*.

B. astyra differs from *sophorae* in having the transverse band of the forewing anteriorly at the end of the cell broken into wedges, the part placed in the cell abbreviated or interrupted by the ground-colour. — Two geographical races: **astyra** *Godt.*, from central Brazil, distributed from Espiritu Santo to Santa Catharina. *astyra*. Hindwing near the distal margin without or with only quite faint traces of a band (name-type); occasionally (in examples from Santa Catharina), however, with a very distinct band (f. **dimidiata** *form. nov.*). Black-brown, forewing with ochreous yellow-brown oblique band, the costal part of which is forked and clouded or darkened. Whilst the distal arm nearly reaches the costa, the proximal is abbreviated or broken up into brown spots. Hindwing mostly unicolorous or with only faint traces of distal bands; ♀ with the ground-colour paler, the band of the forewing a little lighter. — Egg spherical with shallow longitudinal ribs, often running into one another; larvae in bag-shaped nests, a large number together, brown with light longitudinal lines. When they are somewhat grown one can hear the sound of their feeding and can track them by this means. The adult larva reaches 8 cm. in length, with reddish markings on the head; the pupa is smooth, slightly compressed ventrally, either dark brown with black, yellow-edged stripes or bright yellow with lighter stripes and patches. — **philocala** *Stich.* (62 a as *astyra*). Hindwing with distinct rust-red band near the distal margin. The hitherto undescribed ♀ (type in coll. FRUHSTORFER [Geneva]) much larger than the ♂, round-winged like that of *sophorae*, but of greater wing-expanse. Cell-spot on the lower part before the apex reduced. Band of the forewing much narrowed anally. Hindwing occasionally with the rust-red submarginal band entirely absent. Habitat-Rio Grande do Sul, where according to MABILDE the larva occurs from April to November on various palms and lives in an oval bag of 30—40 cm. in length and 10 cm. in breadth, which contains three or four inner divisions. In this the larvae remain for 7—8 months, packed one above another like sardines in a case, sometimes 5—600 specimens together. — **haenschi** *Stich.* shows the band of the forewing bright rust-yellow and has no undulate distal marginal line beneath. Ecuador. — **maritima** *Stich.* has the band of the forewing paler and distally less broken than in *haenschi*; under surface with undulate, in places obsolescent line before the distal margin; the ocelli on the under surface are also less bright, more pale and blind. Venezuela. *philocala*.

B. isthmia *Bates*, from Central America and Colombia, has the wings dark brown above, the forewing with a pale yellow-ochre oblique band, 9—10 mm. in breadth, with the proximal edge irregularly defined, somewhat dentate and bounded by the submedian. Beneath the oblique band is paler, only distinct beyond the cell, in the cell a rounded brown spot. Hindwing above brown, in the ♂ only a narrow ferruginous patch along the lower median vein, in the ♀ without markings. *isthmia*.

B. granadensis *Stich.* (62 a) closely approaches the preceding species, but is somewhat larger. Forewing with broad ochre-yellow oblique band, on the lower discocellular a black-brown spot. Hindwing with only *granadensis*.

quite indistinct traces of a reddish submarginal band, but with conspicuous dark grey mealy spot below the cell between the submedian and the first median vein. Beneath similar to *isthmia*, but the band of the forewing much broader and darker. ♀ differing from that of *isthmia* in the darker ground-colour and the more brilliantly coloured band of the forewing. Colombian specimens are somewhat larger than those from Ecuador. Colombia (Muzo?); Balzapamba in Ecuador to the west of the Andes (750 m.).

ornamen-
talis.

B. ornamentalis Stich. Forewing above with two angled yellow spots in the lower part of the cell, placed one above the other in the shape of a hammer. Beyond the cell a rather broad yellow transverse band, reaching the inner margin. Hindwing ochre-yellow as far as the distal margin, before the margin indications of a dark lunulate line. The colouring of the under surface shows through distinctly. Brazil (Pará?).

2. Genus: **Penetes** Westw.

Closely approximates to *Brassolis* in the style of its colouring and also somewhat in the concave shape of the distal margin of the forewing, so that it is not improbable, as VON BÖNNINGHAUSEN suspected, that the larva approaches that of *Brassolis* and is not forked at the tail. The genus is chiefly characterized by the shape of the forewing, which in both sexes has the apex strongly produced and the distal margin deeply hollowed in the middle. In the forewing the cell is obliquely closed by the three discocellulars, which run in the same direction and nearly straight, the anterior only a little shorter than the middle and posterior, which are of equal length. Precostal cell of the hindwing rather large. Precostal vein simple, only at the extremity proximally curved, the cell likewise obliquely closed by the feebly curved lower discocellular. The genus is monotypical and is confined to Brazil.

pamphanis.

P. pamphanis Westw. (67 b). ♂ above deep dark brown, with large, dull rust-brown spots, not sharply defined, in the disc of the forewing and more or less obscure rust-brown diffuse spots before the apex of both wings. Hindwing with darker veins, glossy grey at the hindmargin; a black-brown hair-pencil placed on the submedian in an extended, scaleless area of a shining, horny appearance. Type from Minas Geraes, in my collection from Espiritu Santo, São Paulo, Parana, Rio Grande do Sul, and a few examples which I myself captured in Sa. Catharina.

3. Genus: **Dynastor** Westw.

This genus is characterized even more than *Brassolis* by the robustness of the body, especially the thorax and abdomen, and the broad wings. From the nearly allied *Opsiphanes* it chiefly differs only in the short, appressed palpus, the short lower discocellular of the forewing, and in having the 3rd subcostal vein arise nearer to the 4th and the upper median vein further from the middle one. ♂ without distinct scent-organ; the eye-spots of the under surface reduced to dots or entirely absent. Both wings very broad, the forewing with strongly curved costa, the subcostal narrowly but distinctly separated from the costal, the distal margin somewhat ventricose, the inner margin nearly straight. Median and submedian slightly thickened at the base, but not strongly inflated as in the Satyrids. Hindwing with the distal margin uniformly rounded, the apex round and the costal margin fairly straight. Cell moderately broad, about half the length of the wing. — Valve basally thickened, in the middle narrowed, distally again widened, chitinized and sharply serrate. Penis relatively short. Saccus posteriorly arched. Uncus strikingly broad, recalling that of the Morphids, its lateral clasps shorter and more than twice as strong as in *Opsiphanes*, valve considerably narrowed posteriorly, distally with long, unequal points. — Of the 3 species belonging here the celebrated *D. napoleon* is unquestionably one of the most magnificent of all the butterflies. The range of distribution of the genus extends southwards to Paraguay, northwards to Mexico.

darius.

D. darius is the most widely distributed species of the genus, occurring everywhere from Guatemala to Bolivia and from Trinidad through the whole of Venezuela and Brazil to Rio Grande do Sul, which is probably explained by the wide distribution of the food-plant. Two directions of variation may be recognized, of which the Andean and purely tropical branch shows large, nearly quadrate apical patches on the underside of the hindwing, whilst the Brazilian subform bears rounder, ocellated costal patches. The hitherto unobserved Paraguay form belongs, strange to say, to the tropical Andean branch, not to the Brazilian. — **stygianus** Btlr., originally described from Costa Rica, is recorded by GODMAN and SALVIN also from Guatemala, Nicaragua, Panama, Colombia, Ecuador and Bolivia, as well as from the Lower Amazon, and in coll. FRUHSTORFER there are 2 ♂♂ from Honduras, which WITTKUGEL discovered in San Pedro Sula. Probably the Trinidad race is also identical. I have no ♀♀ from the purely tropical districts; but according to the material in my collection the ♂♂ show all the differences which STICHEL described as follows in the „Tierreich“: “Larger, with sharper contrasts in colouring. ♂: half-band of the forewing more complete, purer yellowish white, at the upper radial more strikingly diverted from its course, its posterior part being pushed further towards the distal margin. Spot in the apex larger, mostly connected with a small band, the other 3 isolated spots placed

stygianus.

beyond the half-band large, elongate, distally uncertainly defined. Zigzag band of the hindwing composed of larger pointed curves, anteriorly whitish, posteriorly grey-yellow with olivaceous tone; costal margin broadly whitish yellow; border at the distal margin narrow but distinctly defined, anteriorly coloured like the costal margin, from the middle onwards grey-yellow. Under surface of the forewing with small, sharply marked, elongate black costal spot immediately at the apex, the half-band very little noticeable, the three isolated spots more indefinite, the posterior one occasionally cleft longitudinally. Anterior eye-spot of the hindwing extraordinarily broad, flattened, rectangular with the short sides rounded. It occupies nearly or more than one third of the interneural space, anteriorly and posteriorly touches the costal and subcostal for its entire breadth, is at these long sides only distinguished from the ground-colour by the absence of the striation, but at the short sides shaded with dark brown; its central part is longitudinally somewhat darker and traversed by 2 lines of small white spots. Central eye-spot similarly developed, only somewhat shorter, behind it sometimes a white-centred ring-spot. Posterior eye-spot as in the typical subspecies, but mostly larger and more sharply marked. Distal margin of the hindwing strongly undulate." The ♂♂ from Surinam in my collection are not identical with *stygianus* Btlr. from Honduras, differing in the somewhat narrower whitish yellow band and the smaller patches on the forewing, also in the darker, deeper coloured under surface. But still less do they agree with the figure of *anaxarete* Cr. ♂ (*anaxarete* Stoll ♀), which has strikingly small spots on the forewing and relatively large triangular markings on the hindwing. In the ♀ which STOLL figures the oblique band of the forewing is even broken up into separate small spots hardly as large as lentils, and as HÜBNER also represents a ♂ similarly small-spotted it would seem that for some time only such peculiarly coloured, aberrant specimens were brought to Europe from some particular locality. — *mardonius* subsp. nov. (62 b) closely approaches *mardonius*. *anaxarete* Cr. in the narrower, almost uniformly broad band of the forewing, and also agrees with it in the shape of the nearly rectangular costal patch on the underside of the hindwing. On the other hand the zigzag band on the hindwing above is twice as broad and the under surface, in accordance with the general character of the Paraguay butterflies, is paler and without the purple dusting of *anaxarete*. Paraguay, from two ♀♀ in coll. FRUHSTORFER. — *darius* F., described from Brazil, is the commonest subspecies in collections; *darius*. both sexes bear a relatively large double patch of greenish white on the upperside of the hindwing, on which are placed regular series of undulated, greenish, pointed curves. ♀ sometimes enormously large. Espiritu Santo, Rio de Janeiro, distributed to Santa Catharina. — *icterica* Stich., from Rio de Janeiro, is smaller than the type-form, the band and the three isolated spots on the forewing yellow instead of whitish. Zigzag band of the hindwing and a narrow marginal stripe at the distal margin anteriorly yellow, posteriorly dirty green-yellow. Larva yellow-brown, later grey-brown or green, longitudinally striped, with brown head, which in the adult larva bears short hairs at the margin. Along the dorsum a series of round dark spots, enclosing light dots anteriorly; small, bristle-bearing tubercles are scattered over the surface and the anal end terminates in a forked tail. On Bromeliaceae; full fed in 2 months. Pupa light green with brownish longitudinal stripes and dark shades and speckling; yields the butterfly in 12 days (W. MÜLLER). — *faenius* subsp. nov. inhabits Rio Grande *faenius*. do Sul and is somewhat smaller than *darius* from Central Brazil, with somewhat smaller median spots on the upperside of the forewing, and the hindwing lacking the large yellowish white costal patches, in place of which there are greenish diffuse spots, which do not differ appreciably from the adjoining, irregularly shaped greenish pointed curves. The under surface agrees somewhat with that of *mardonius*; it shows the typical paler colouring of all the Rio Grande butterflies. ♀ dusted with almost pure white, particularly in the distal area. All the ocelli obsolescent, the median eye-spot in most examples entirely absent. Claspings-organs described in the generic diagnosis. From three ♂♂, two ♀♀ from Candelaria in coll. FRUHSTORFER. According to MABILDE there are two generations. The larva is green with two figure-shaped marks on the head and appears in January and February, and again July and August, on Ananas and bananas. It changes into a green pupa in March — April, and August—September, and after 30 to 60 days produces the common and widely distributed butterfly.

D. macrosiris, in contrast to the preceding species, is extremely rare; only a few examples are known, mostly of only one sex. — *macrosiris* Westw. comes from Cayenne; it is black above with a slight violet-brown tinge, the distal border lighter, costal margin striated with black and white. The oblique band of the forewing, placed distally to the cell, is narrow, whitish, terminating at the first median vein, but continued as two small, isolated whitish spots. Distally to the oblique band two black, lighter-margined spots showing through from beneath, anteriorly with two small, crescentic or obtusely sagittate white spots placed near the apex. Hindwing with lighter distal border, towards the apex widened into a whitish spot. — Of *strix* Bates (62 b) only ♀♀ are yet known. The name-type was from Guatemala, but it was afterwards found also at Cordoba, Mexico, by HÖGE. Our figure is from a Honduras specimen in the FRUHSTORFER collection. Deep dark brown, costal margin of the forewing striated with white as far as a whitish oblique band placed beyond the cell, continuing which there is an elongate white spot. In the apical area 3 small white spots. Hindwing with whitish apex, otherwise uniformly dark. Under surface very characteristic, particularly in the irregular shape of the ocelli between the apex of the forewing and the oblique band. — *hannibal* Oberth. came from Colombia and differs in having a more prominent white area on the forewing from *macrosiris* Westw., the type of which OBERTHÜR acquired

pharnaces. with BOISDUVAL's collection. — *pharnaces* *Stich.* is smaller than the preceding subspecies. The white oblique band on the upperside of the forewing somewhat broader, more sharply defined, although somewhat dusted at the proximal side, posteriorly terminating obtusely before the middle median vein and not running out towards the distal margin as in *macrosiris strix*. The single spot posterior to it much reduced. Hindwing with narrower white bordering. On the under surface the transverse striation throughout coarser, on the forewing red-brown; it disappears beyond the cell and in the distal area, in the submedian interspace there is only an indistinct shading. In the cell of the hindwing and beyond it the striation is widened into narrow stripes and in places reticulate, the ground-colour of the wing almost rust-red instead of yellowish. The elongate eye-spot in the costal area light red-brown, less sharply expressed, the other two ocellated spots in the radial and lower median cellules also only indistinct. Border at the distal margin narrowly greenish. Only 1 ♂ from Bolivia (Coroico, Yungas, at 2000 m.) known.

napoleon. **D. napoleon** *Westw.* (62 b) seems to be an archaic, nearly extinct species, exclusively confined to the state of Rio de Janeiro, and even there only recorded from Petropolis; from time to time the splendid butterfly has been successfully bred from the larva. The larva, although known for over 30 years, has not yet been described. According to VON BÖNNINGHAUSEN it lives on one of the Bromeliaceae, with non-dentate leaves. ♀ considerably larger than the ♂, which we figure, the underside of the hindwing with somewhat lighter orange marginal area, as in *darius* *F.* Forewing, however, with black median area, hindwing throughout ochre-yellow, dusted with lighter near the base. The black veins stand out very sharply against the ground-colour.

II. Subfamily: Caligoninae.

Larva with forked tail and with horns on the head.

4. Genus: **Dasyophthalma** *Westw.*

A small but interesting genus, which in general aspect and also in its habits recalls the Indian *Thaumantis*, particularly *lucipor* and *odana*. Only one species (*creusa*) has the colouring darker. In the densely haired eyes *Dasyophthalma* differs from all the other Brassolids. Structurally it approaches the genus *Caligo*, but the precostal cell is strikingly broader, especially considering the smaller size of the body. Head and body more slender than in the preceding genus. Antenna less than half the length of the wings. Forewing triangular with the inner angle rounded, hindwing in the ♂ with the apex pronounced and the distal margin undulate. Wings above black or quite dark brown, sometimes with a bright blue reflection, the under surface with pupilled ocelli. The ♂ bears on the upperside of the hindwing a scent-spot at the posterior margin of the cell. Like its Indian relative, *Thaumantis*, the species of *Dasyophthalma* exclusively inhabit dense forests, where they always keep near the ground, only leaving the damp cover when baited with hung up bananas. One species (*rusina*) I have never seen flying at all; all my examples I owe exclusively to this bait, which they visit together with *Eryphanis reevesi*, *Prepona* species and occasionally a *Morpho catenarius*. Probably they have all only one brood. According to my recollection they appear in Santa Catharina in February, only worn examples are still to be taken by the end of March and at the beginning of April they disappear completely. Concerning the early stages nothing further is known than that the larva lives on bamboo. Distribution: central and southern Brazil.

creusa. **D. creusa** splits up into two local races: **creusa** *Hbn.* (62 c), only known as yet from Santa Catharina and Rio Grande do Sul, appears to be very local, but to occur in abundance in suitable localities. My collector, JULIUS MICHAELIS, and I myself captured nearly 1000 examples in the course of 2 years at Theresopolis and in the valley of the Capivary River. At Blumenau it seems only to occur sparingly and in Rio Grande, at the extreme limit of its range, it is one of the greatest rarities. I possess no ♀♀ from Rio Grande. The upper surface is black, the forewing traversed from the apex to the middle of the inner margin by a bone-yellow gradually widening oblique band. The ♀, of which we figure the under surface, is considerably larger than the ♂, with broader bands, beneath paler grey-green. Upper surface: hindwing only with two or three yellowish splashes in the middle of the costal margin. The median band of the forewing more vertical, broader than in the ♂, less pure yellow, more greenish, connected with the costal border by a transcellular row of indistinct spots. Before the apex of the cell on the hindwing somewhat dusted with greenish. ♂ with long yellowish hair-tuft at the basal part of the cell of the hindwing. Flies February to April. *creusa* is par excellence a visitor to sweets and comes at any hour of the day to hung-up bananas; frequently it is even tempted at night by the sweet, rotting fruit and I found it repeatedly as a not particularly welcome addition in the killing bottles in which I was taking the baited Heterocera. — *baronesa* *Stich.* is a not sharply differentiated local form discovered by my collector J. MICHAELIS in Espiritu Santo, and apparently also occurring in Rio de Janeiro, where according to VON BÖNNINGHAUSEN it is not very rare at Petropolis. ♂ distinguishable from

creusa by the more complete yellowish median band on the upperside of both wings. ♀ scarcely differing above, beneath with smaller and more regular oval median ocelli.

D. *rusina* may be divided into two local races. The species is everywhere rare and is distinguished by the brilliant, intensive deep blue reflections on the basal part of the forewing and the median area of the hindwing. *rusina* Godt. (= *delanira* Hew. ♀) is only certainly known as yet from Santa Catharina. ♂ with black hair-pencil near the base of the hindwing. The light band on the forewing runs parallel with the distal margin and is continued in the same direction across the hindwing. — ***principesa* Stich.**, discovered by MICHAELIS in Espiritu Santo, seems to occur also in Rio de Janeiro, where it was observed on the Corcovado and at Petropolis by VON BÖNNINGHAUSEN, who further states that the larva lives on bamboo. Quite resembles the typical *rusina*, except that the light band on the wings is somewhat less broad, on the forewing sometimes widened in the middle, and the blue reflection on the hindwing more extended. Under surface in both sexes lighter throughout than in *rusina*, the almost white median band without darker orange-coloured bordering, the distal area not grey-brown as in *rusina*, but distinctly divided into two parts, the submarginal part reddish brown, the distal predominantly striated with whitish grey.

D. *vertebralis* Bthr. (62 a) is a sharply differentiated species, and was captured together with *creusa* in Espiritu Santo by J. MICHAELIS, so that the locality "Para", erroneously given by its author, has been corrected. Under surface as in *creusa* with three large red-brown, black-ringed median ocelli, placed in a light yellowish patch. Band of the forewing narrow, oblique, composed of spots. Under surface of the hindwing with 3 ocelli: the 1st in the middle of the costa, the 2nd distally to the cell, the 3rd in the posterior median cellule. ♀ larger, with broader wings and duller colouring, so that the striae of the under surface show through. The band of the forewing runs more steeply.

5. Genus: **Opsiphanes** Westw.

Differs from *Caligo* in the more pointed and not so excessively large wings, the larger precostal cell and the relatively stronger body, from *Brassolis* in the longer palpi. Head large, with strongly rounded eyes, frons short, palpus on the underside densely clothed with bristly hairs, upcurved in front of the face, extending but little beyond the head. Antenna gradually thickened, nearly half the length of the costa. Thorax very broad and strong. Forewing mostly rather pointed, the distal margin usually somewhat concave; inner margin straight. Subcostal five-branched, branches 1 and 2 arising before, branch 3 considerably behind the end of the cell, the fourth running into the apex, short-stalked with the fifth. Cell of the forewing short and broad. Hindwing almost round, only a little elliptical, with the apex rounded. The scent-organs of the ♂♂ are hair-pencils on the upperside of the hindwing, which can be spread out in a stellate form. Abdomen powerful, in the ♂ with lateral protuberances. Clasp-organs Satyrid-like, extremely simple. Uncus slightly curved, with 2 lateral clasps, harpe similar to that of the European *Karanasa* (= *Satyrus* of the *huebneri* group, vol. I, p. 127), proximally somewhat widened, in the middle narrowed, distally with projecting ventral point. Egg according to W. MÜLLER spherical, finely ribbed. The larva appears after 10 days, and when young is brown, striped with yellow or red, with black head. When full-grown the head shows a crest of posteriorly directed horns and the face is striped with red-brown. Body thickened in the middle, with 12 longitudinal lines, terminating posteriorly in a forked tail. The larvae live on bananas and rest on the underside of the gigantic leaves, along their midrib. Pupa less compressed than those of the preceding genera, green-yellow, the wing-cases with brown margins and stripes and with a silvery spot. According to Dr. HAHNEL some species emit a scent of vanilla. They remain all day among the lower branches and round the trunks and are fond of congregating on fallen fruit. Some species can be baited with bananas. The species of the *batea* group prefer the light undergrowth, where they are found in the so-called "Waldschänken", i. e. on tree-trunks which exude sweet or fermenting sap. Dr. HAHNEL also met with them even at early dawn near human habitations on refuse, about which they flew restlessly.

Copulatory organs, judging from those of *O. invirae remoliatu*s Fruhst., remarkably Satyrid-like, scarcely differing from those of the Palearctic *Eumenis*. Uncus hook-shaped, slightly bent downwards, two lateral clasps extremely delicate; valve quite regularly of the simplest structure, basally somewhat thickened, but not so markedly as in the genus *Dynastor*, slightly incised in the middle, the ventral distal end projecting as in *Eumenis cordula*, the dorsal somewhat retracted, slightly chitinized, with two excrescences of unequal size. The whole ventral part of the valve long-haired. Penis very broad, saccus quite normal, rather long, its proximal end not appreciably widened.

Four groups, of which *Opoptera* is so nearly entitled to generic rank that it is only here treated as a sub-genus because its author so regarded it and in order to avoid splitting up a very natural genus. *Catoblepia* on the other hand is only maintained on account of the secondary sexual characters, as there are no constant structural differences at all.

Precostal cell of the hindwing longer than broad, **Opoptera**.

Precostal of the hindwing higher than broad, **Opsiphanes**.

Cell of the hindwing narrow, middle and lower discocellulars nearly straight, **Catoblepia**.

Cell of the hindwing narrow, middle and lower discocellulars quite weakly curved, **Selenophanes**.

Group *Opoptera* *Aur.*

The species of this interesting little group strongly recall Satyrids in their thin, delicate wings. The genus, or rather subgenus, as which its author introduced it, was formerly united with *Opsiphanes*, but is rightly separated on account of the broader precostal cell of the hindwing. Otherwise *Opoptera* differs from typical *Opsiphanes* also in having the cell of the forewing strikingly broad and that of the hindwing short, relatively narrow distally. The precostal cell of the latter is longer than broad. Head moderately small, with strongly rounded, naked eyes and hairy frons. Tongue strong. Palpus beneath with bristly hairs, extending little beyond the head. Antenna considerably longer than in the preceding, in the ♂ often more than half the length of the costa, little thickened at the end. Thorax not so robust as in *Opsiphanes*, the whole build sometimes strongly Satyrid; forewing with rounded apex and large, broad cell, reaching to the middle of the wing. Costal and subcostal separate throughout their whole course, the latter 5-branched, branches 1 and 2 arising before, 3 behind the end of the cell, 4 and 5 short-stalked. Hindwing ellipsoid, with slightly undulate distal margin, lower median vein with a scent-pouch. Abdomen slender and rather long.

Concerning the early stages nothing is known. The imagines with one exception (*bassus*) are true forest butterflies, which flutter about with a weak flight near the ground, lead a shy and sluggish existence in the bamboo thickets and by preference keep near the water-courses. Some of them are certain to be met with where fermenting sap exudes from holes bored by insects in the trees of lower growth. At such places they sometimes sit for hours with the wings closed and it is in this way that they are most easily caught. They are very local and three out of the six known species inhabit southern Brazil.

Sect. I.

Apex of the forewing angled or rounded, hindwing of the ♂ with a hair-pencil in the cell or a brush-shaped hair-tuft at the submedian.

- O. aorsa** recalls Indian *Lethe* and *Zophoëssa* in the tailed hindwing and the upper surface is distinguished by very narrow bands and by a purple gloss which covers these bands in their marginal part. Previously only known from Brazil, *aorsa* was recently discovered also at the sources of the upper Amazons, so that there are now four local races to record: **aorsa** *Godt.* (63 a), the type of which probably came from Rio de Janeiro, extends southwards to Rio Grande do Sul. It is everywhere rare, and I cannot remember to have found it on the banana-bait which was so commonly visited by *Dasyophthalma*, *Caligo*, *Eryphanis reevesi* and other species of *Opsiphanes*. It is a species of the larger forests, never leaving the shade of their tall trees. Moreover its period is very short (February and March) and in the course of a year one probably meets with scarcely more than half a dozen examples, and even those are mostly damaged on account of their delicate wings. Forewing in the ♂ with pale ochre-yellow oblique band, beginning beyond the middle of the inner margin and, sometimes slightly interrupted, running to the anal angle. In the apex small white spots. Hindwing with distinct marginal markings. Of the narrow bands crossing the cell of the forewing the proximal is as a rule dull whitish or brown, interrupted in the middle, the distal complete, of silver-white colour, reaching to the middle part of the median.
- litura*. In ab. **litura** *Fruhst.*, from Espiritu Santo, the marginal markings on the upperside of the hindwing have become brown-violet. — **fuscata** *Stich.* is the same shape as the typical subspecies but considerably smaller, hindwing with more rudimentary tails. ♂; above black-brown, the bands near the apex and distal margin of the forewing strongly shaded with brown, particularly in the posterior part quite blurred. Hindwing only showing quite indistinct light spots at the margin. Beneath the light angled band in the distal area has almost entirely disappeared, only a small yellowish white spot at the costal margin and another in the anterior angle of the lower median cellule persisting, together with a few whitish splashes in place of the anterior part of this band. Submarginal line at the distal margin, and correspondingly also the boundary of the dark part of the wing adjoining the distal area, strikingly dentate. Hindwing considerably darker than in typical *aorsa*, particularly in the basal and hindmarginal areas, the ground-colour there strongly tinged with violet. At the border of the distal margin a row of light, shallow lunular spots on the dark brown undulate line stands out conspicuously against the darker marginal dusting. In the ♀ the upper surface is vaguely rust-red, forewing with narrow light ochre-yellow band, similar to that of the typical subspecies, in which, however, the branch running anteriorly (towards the apex) from the top of the obtuse bend in the distal margin is lacking. Distal markings of the hindwing weak, faint, in the anal angle entirely disappearing. From the Upper Amazon (Manaos).
- hilara*. — In **hilara** *Stich.*, from Ecuador and Peru, the ground-colour is darker, above deep black-brown, the band of the forewing deep yellow, in the anal part notched proximally at the veins. Hindwing above unicolorous dark with white fringes, not distinctly spotted before the distal margin. Beneath the transverse band in the cell of the forewing is broken up into spots. Forewing and basal area of the hindwing striated with milk-white.
- arsippe*. **O. arsippe** has 2 geographical subspecies. **arsippe** *Hopff.* Oblique band of the forewing ochreous, almost as in *aorsa*, but darker, posteriorly strongly angled, otherwise smooth, distally somewhat broken. Of the anterior three small white spots in the apical area the middle one is placed somewhat distally; a fourth appears

as a small crescent or curved streak at the distal boundary of the eye-spot, which shows through from beneath. In the ♀ the distal border of the hindwing is of a somewhat lighter tone than in the ♂. Near the costal margin in the apical area there is in addition an isolated ochre-yellow spot; the tail-like point at the lower median vein darker brown. Length of the forewing ♂ 40—41, ♀ 42 mm. Under surface less variegated than in *aorsa*. Southern Peru. Very rare, only received from Chanchamayo. — **bracteolata** Stich. Darker than the preceding. White apical spots of the forewing very small, oblique band distally to the cell broken up into three small, isolated spots. Subapical spots at the distal margin very small, tail-like appendages of the hindwing shorter. Middle band in the cell of the forewing beneath continuous. The two small silky white spots between the medians lie like silver spangles on the dark ground. Before the distal margin of the forewing a lighter, whitish, narrow stripe, following the former. 1 ♂, from Bolivia.

O. syme replaces *sulcius* in Central Brazil and seems to be a rather rare species, of limited geographical distribution. Two local forms: **syme** Hbn., with the name-type from the state of Rio de Janeiro, where it is regularly found at Corcovado and in the Organ Mountains near Petropolis. Similar to the preceding species, but the yellow oblique band of the forewing much reduced and partially broken up into small spots; on the hindwing the row of yellow submarginal spots likewise smaller. In the cell of the forewing the markings of the under surface show through above. Of the eye-spots on the underside of the hindwing the first, placed in the middle below the costa, has a brown ground, which gives it a somewhat blind appearance, while the one placed between the median veins is more brightly coloured. The ♀ has before the distal margin of the hindwing somewhat more distinct yellow spotting and on the black colour of the disc a blue reflection. — **fumosa** Stich. (65 b, as *syme*) has the ground-colour somewhat darker than examples from Rio de Janeiro, the hindwing in particular is suffused with blackish and the submarginal row of yellow lunules nearly obsolete, merely indicated by a lighter tone of colour or only persisting in the anterior part. Espiritu Santo, first found by my collector, JULIUS MICHAELIS, rather rare.

O. sulcius Stgr. (63 a) comes from South Brazil, where it represents the Central Brazilian *syme*. It resembles the latter, but differs in the bright ochre-yellow band of the forewing, which is there narrow and dentate and terminates before the anal angle; in *sulcius* on the contrary it is broad and reaches the anal angle. — The form **sodalis** Rüb., from São Paulo, is strongly suffused with yellowish above and beneath, especially in the proximal area of the wings, and the marginal markings on the hindwing more extended.

SECT. II.

Forewing with the apex more pointed. ♂ without true hair-pencil. The lower median of the hindwing arises not far from the base and forms close behind the cell a deep pouch filled with mealy scales.

O. staudingeri Godm. & Salv. (63 b). Size of the preceding; upper surface bright dark brown, even the usually deep black apex brown. Before it a yellow-red oblique band, partially darkened with brownish, beginning before the last third of the costal margin, running obliquely towards the middle of the distal margin, then bent and running parallel with the distal margin towards the inner margin, terminating in almost a point at the submedian. Beneath the hindwing has a faint ring-shaped mark in the middle of the cell. The anterior ocellus, in the middle of the costa, is the larger, with brown ground, the one between the medians the smaller, with blackish ground and brighter markings. Panama; very rare, only a few examples known; the ♂ figured, from coll. FRUHSTORFER, came from Costa Rica. A ♀ from coll. STAUDINGER, from Chiriqui, was first described by STICHEL as follows: "Somewhat larger than the ♂, ground-colour of the upper surface lighter, light reddish brown. Band of the forewing broader, less sharply angled, running posteriorly in a slight curve. Border at the distal margin of the forewing ochre-yellow. Under surface as in the ♂. Length of the forewing 46 mm."

Group *Opsiphanes* Westw.

O. batea is one of the most interesting species of the genus; its range indeed is only a comparatively restricted one, being confined to subtropical Brazil and the adjacent countries, but it offers little resistance to climatic influences even at short distances, and the result is a series of geographical races concerning which a great deal has already been published, without, however, elucidating them satisfactorily. The centre of distribution for the collective species seems to be the province of Santa Catharina, from which we already know two representative species, probably on account of the more thorough exploration of this district. All that is certain is that *batea* occurs from Espiritu Santo to Rio Grande do Sul, changing gradually from north to south and becoming progressively more melanotic in colouring southwards. Together with quite dark forms, however, there occur in both the southern provinces of Brazil also retrogressions to the lighter name-type. We can hardly regard them as seasonal forms, as according to my experience the species of the *batea* group have only one generation, which occurs in the spring and disappears in April and May, when the cool nights begin. The clasping-organs have not yet been investigated, but according to STICHEL these lead to no result in this genus, as the organs themselves are not yet sufficiently differentiated. The early stages are not known,

- and thus the separation or union of the several forms still remains more a matter of instinct or personal choice than of experimental knowledge. If here again I deviate from the previously frequented path, it is on the ground of a delightful accumulation of material, which I have been fortunate enough to get together. —
- batea*. **batea** Hbn. (62c), the name-type, probably came from the state of Rio de Janeiro; at any rate HÜBNER's figure, which is not so good as most in his works, shows the principal distinguishing mark of the Rio specimens, the almost vertical black distal border of the forewing, which is not expanded proximally (towards the cell) and has its inner edge almost straight. All the other forms, on the contrary, have an apical spot extending as far proximad as in our figure (61a 2, *subsericea*) or even further and similar or still finer and more numerous proximal incisions. Moreover all the representative forms bear a more or less distinct black spot at the apex of the cell of the forewing, which apparently is only absent in *batea* from Rio de Janeiro. Upper surface of the hindwing with less of the dull red-brown gloss. Under surface with parts of the cell of the forewing whitish
- asphærus*. and with longer, almost whitish yellow median band, posteriorly tapering to a point. — **asphærus** *subsp. nov.* is a larger race from Espiritu Santo, the most northerly locality known, in which the forewing has the three whitish yellow subapical patches already somewhat faint and the distal border more deeply indented. ♂ almost, ♀ entirely without black spot at the apex of the cell. Marginal area of the hindwing in the ♀ extending to the cell, without any trace of red-brown. The whitish parts of the under surface more extended than in *batea* Hbn. Very rare, while according to VON BÖNNIGHAUSEN *batea* is very common in the Organ Mountains
- glaukias*. near Petropolis. — **glaukias** *subsp. nov.* is a local form from the province of São Paulo, very nearly allied to the name-type; smaller than *asphærus* and *prægrandis* (61a), but appreciably larger than *batea*. Subapical patches darker than in the preceding races, ochre-yellow. Basal area of both wings of a deeper colour, more inclining to red-brown. Distal border proximally rather regularly but not very deeply incised. Cell-spot of the forewing rudimentary. Under surface hardly differing from *batea* in the shape of the ocelli and the
- dubia*. general coloration. From three ♂♂ in coll. FRUHSTORFER. ♀ unknown. — **dubia** Rüb. likewise came from São Paulo and according to STICHEL is a very small, somewhat abnormal form, with paler ground-colour and
- panormus*. strikingly lighter distal margin. — **panormus** Rüb. is apparently not rare at Blumenau and even somewhat further south, at Theresopolis in Santa Catharina, I myself took numerous examples in the "Waldschänken" already mentioned, which I searched twice daily. According to the material in my collection *panormus* chiefly differs from *batea* in the black distal border of the forewing extending to the apex of the cell and leaving either no yellow-brown spot at all or only a very reduced, narrow one which never reaches the costal margin, whilst in *batea* and its offshoots it always runs from the first median to the costal as a distinct, sharply defined transcellular band. On the under surface the striation is predominantly black instead of red-brown. RÖBER's type, which is in my collection, differs from all the examples of *batea* to which I have access in having a beautiful yellow submarginal punctiform spot on the underside of the forewing between the middle and lower medians.
- beata*. — **beata** Fruhst. (61a as *subsericea*) still possesses quite distinctly the *batea*-character and differs from *panormus* chiefly in possessing a broad yellow band-like transcellular spot, distally dusted with reddish, on the forewing, which is particularly well developed in the ♀. The black distal border of the hindwing somewhat narrower than in *panormus*. Santa Catharina, Theresopolis, up to about 1500'. Appears about January and flies until March, preferring the edge of the woods or the so-called Capoeira, the spare, dwarfed growth which springs up where the forests have been cut down. The butterflies are fond of the sweet sap of certain shrubs which exudes from holes bored by small beetles and besides Lepidoptera also attracts enormous numbers of *Meli-*
- didymaon*. *ponae*, *Lucanidae*, *Elateridae* and sometimes also *Gymnetis* (*Cetoniidae*). — **didymaon** Fldr., the locality of which was incorrectly given by STICHEL as Sta. Catharina, almost certainly came from Rio Grande do Sul, judging by the type before me from the Tring Museum, which I have been able to compare with sufficient material from my collection. The subapical patches of the forewing about as in *batea*, small, duller yellow than in *panormus* and *beata*, but apparently very variable, in the ♀ again very large, nearly white. The black marginal area of the forewing much widened, bearing either no yellowish transcellular band or only an indistinct one, which in the ♀ is also darker and more reddish. Distal border of the forewing sometimes narrow (type) or again nearly reaching the cell. Hindwing above with rust-red tinge proximally to the black marginal area. Under surface contrary to the general character of the Rio Grande fauna predominantly blackened, the transcellular band of the forewing a mere thread, ocelli of the hindwing with delicate, scarcely appreciable yellow bordering, on the other hand the nearly black outer border much widened. São João da Reserva, Rio Grande do Sul, 3 ♂♂, 1 ♀ in coll. FRUHSTORFER. Appears at the end of the summer and prefers the edges of the woods or
- subsericea*. light thickets (MABILDE). — **subsericea** Fruhst., analogous to *beata* Fruhst., is the light form from Rio Grande do Sul and differs from *didymaon* in having a broad yellow transcellular zone on the forewing. Smaller than the other *batea* forms, wings more rounded, and in the ♀ scarcely undulate. Black distal border of both wings strikingly narrow, proximally inappreciably undulate, but especially on the hindwing broadly tinged with dark rust-red, as in *didymaon* Fruhst. Hindwing with slight silky gloss. Apex of the cell on the forewing in the ♂ only quite faintly red-brown, in the ♀ spotted with black. Under surface: darker than in *beata*, hindwing only with a short light band, which does not extend beyond the cell, otherwise uniformly striated with red-brown throughout. Ocelli oblong, relatively small. *subsericea* agrees with the type in the very small dull yellow subapical patches of the forewing, but differs beneath in the darker general colouring and in having the yellow

band at the apex of the cell of the forewing broad instead of filiform. — *praegrandis* *Fruhst.* (61 a) on the *praegrandis*. whole approaches *asphærus*, but is even larger. Above with the black distal border deeply incised proximally, but scarcely extending nearer to the cell than in *beata*. Apical spots of the forewing very large, light yellow. *praegrandis* differs further from its Brazilian allies in the following points: distal border of both wings proximally more deeply excised, much lighter towards the costa. Abdomen above lighter brown. Beneath: distal part of the forewing broader and lighter yellow-grey with larger black ocelli. The triangular subapical spot striated with white and more extended, the transverse bands of the cell light brown. Hindwing: the apical ocelli more elongate, the anal ones with broader light brown bordering. The yellowish discal band light yellow, more extended, broader than even in *beata beata* and running as far as the anal ocellus. The brown submarginal band of the forewing much narrowed towards the apex, anal ocelli of the hindwing with fuller light blue iris, filling almost half the ocellus instead of the small "lunula" of *batea*. Locality: Paraguay. *praegrandis* passed for a long time in collections under the name "*didymaon* *Fldr.*" But FELDER adds to his diagnosis: "Our examples are all smaller than *batea* *Hbn.*, among which they seem to occur", which contradicts this determination, and at the same time shows that forms analogous to *beata* were already known to FELDER, which he was observant enough to separate from his *didymaon*.

O. catharinae *Stich.* (= *wilhelminae* *Röb.*) exclusively inhabits Santa Catharina and is undoubtedly *catharinae*. far the rarest of the two or three species of the *batea* group. Its specific right is beyond all question; the principal distinguishing characters consist in the absence of the hair-pencil in the cell of the hindwing, the more rounded shape of the wings and in the basal area on the upperside of both wings being by far the lightest, nearly yellow, only reddish at the edges, and the veins red or black to the middle of the wings. Distal border of the hindwing very broadly grey-yellow. Transcellular spot and apical bordering of the forewing similar to that of *beata* *Fruhst.* (61 a). Apical patches of the forewing alike in both sexes, very light, almost pure white. Ground-colour of the ♂ ochre-yellow, both wings with broad black margins, bordered with lighter grey-black; the yellow colour shaded with rust-red where it touches the black distal part. The proximal boundary of the latter begins not far beyond the cell at the costa, runs parallel with the end of the cell to the upper median, then projects basewards again between the upper and middle medians, and beyond the latter once more recedes considerably towards the distal margin. The whole boundary-line is dentate but not sharply. Discocellular proximally brownish, distally blackish. In the black distal part a row of 5 whitish spots, running in a curve from the costa, the last is a mere dot. The row of spots terminates between the lower radial and the upper median, the spot being here replaced by the apical eye-spot, which shows through from beneath. Black distal part of the hindwing of the same extent as in *O. didymaon* *Fldr.* Proximal boundary uncertain, not far from the end of the cell running parallel with the distal margin. At the inner margin a bare friction-patch with a small hair-pencil at the submedian. Under surface nearly as in *O. didymaon*, on the whole with a somewhat lighter tone, a brownish, dark-edged band at the discocellular broader than in that species, the dark-shaded stripe placed proximally to the two marginal lines, corresponding to the black distal part of the upper surface, bent somewhat towards the distal margin behind the lower median. Type probably from Blumenau, from whence also came the examples described by RÖBER, which I have before me for comparison. I myself took *catharinae* at Theresopolis in company with *O. batea beata* *Fruhst.* and *O. didymaon* *Fldr.* at the same exudations of sweet or fermenting sap in the underwood of the river-valleys, but much more sparingly than the other two forms.

O. bassus commonly occurs in company with *O. batea* *Hbn.* and *didymaon* *Fldr.*, but in contrast to these it ventures even in the greatest heat of the day on to sunny grass-lands with scattered bushes, and once when chasing it I trod on a poisonous snake 2 m. in length, crawling in the grass, which perhaps was also hunting the butterflies. Two local forms: **bassus** *Fldr.*, described by its author without more exact locality as from *bassus*. "Brasilia meridionalis"; type probably from Blumenau in Santa Catharina; differs above only in the narrower transcellular band of the forewing and beneath in the considerably smaller ocelli from *luteipennis* *Btlr.* (61 a), *luteipennis*. which according to a ♂ before me from Rio Grande do Sul is still more strongly tinged with red-brown above than the *bassus* ♂♂ taken by me. The nomenclature is somewhat arbitrary, as BUTLER described his *luteipennis* without any locality. I have only applied the name to the Rio Grande form to prevent its sinking as a synonym and to avoid creating a new one. — **oculata** *Stich.* designates a poorly coloured aberration *oculata*. which happens to have the anal ocellus of the hindwing marked above also.

O. boisdualii *Westw.* (62 d) is a species of restricted range, noteworthy for its light yellow colouring and known to appear in the twilight and to have a swift and powerful flight. Originally described from Mexico, it extends southwards only to Guatemala and Honduras. Under surface with the same tone of colour as the figured upper surface, a costal stripe darkened, with whitish transverse striation, the rest of the wings irrorated and watered with brownish or rust-red almost throughout. Hindwing with two ocelli; the anterior one oval, distally somewhat flattened, finely margined with black, interiorly tinged with rust-brown and ornamented with a white curved streak. Posterior eye-spot round, the pupil yellowish with a small white curved streak, the border blackish-dusted, the whole margined with ochreous and finely surrounded with rust-brown. Between the two, arranged in a crescent, three round light spots or patches are noticeable in the striated surface, the posterior two sometimes white-pupilled. In the distal marginal area two rather distinct rust-brown

undulate bands are formed by the closer striation and shading. The distal margin itself is somewhat duller, especially anteriorly. Abdomen with lateral friction-pads. The ♀ larger, broader-winged, with a band-like light patch behind the cell. Distal margin of the forewing nearly straight.

- O. cassiae** inhabits tropical South America from Colombia to Bolivia and from Guiana to Rio de Janeiro and Santa Catharina. Common wherever its food-plant, the edible banana, has been planted, on the leaves of which the light green larva lives. The species probably flies all the year round, and examples are known from Surinam which perhaps belong to a dry-season form. The separated branch-races are not very sharply divided; in the Central Brazilian races it cannot be proved with certainty whether they are due to geographical or only climatic influences. — **cassiae** *L.* came from Surinam, but is apparently distributed as far as eastern Colombia. Forewing with a yellowish band, much more narrowed anally than in *lucullus* (61 a); hindwing with a short yellowish marginal band from the apex to about the upper median, thence onwards narrowed and mostly only continued as reddish shadows. Underside of the hindwing with a very large, nearly retort-shaped apical eye-spot, sometimes distally produced, and a small, rounded, yellow-ringed anal ocellus. Between the two occasionally some blind accessory eye-spots. **cassiculus** *Stich.* is a smaller form, perhaps belonging to the dry season. The ♂ has the band of the forewing somewhat narrowed, sharply cut posteriorly by the median veins and showing a tendency here to break up into spots, and with both its proximal and its distal edge deeply incised. Hindwing unicolorous dark brown, at most in the apex one or two quite blurred, scarcely perceptible small, narrow, diffuse spots. ♀ somewhat larger, band of the forewing but little outcurved proximally on the cell, posteriorly strongly notched at the median veins, the veins themselves there somewhat dusted with brown. Hindwing only with some small pale ochre-yellow apical spots or the short beginning of a dentate marginal band. — **pseudocassiae** *Fruhst.* ♂: length of the forewing 42 mm. This interesting, small race forms a transition from *cassiae* to *tamarindi*, as it bears on the forewing a compact, dark ochreous band as broad as in *cassiae decentius* *Fruhst.* and has the hindwing unicolorous, entirely without markings, like *tamarindi*. On the under surface *pseudocassiae* is about intermediate between *tamarindi* and *xiphos* in marking and colouring.
- pudicus**. *Manaos.* — **pudicus** *Fruhst.* inhabits Bahia. Transverse band of the forewing light yellowish, of about uniform breadth from the costa to the anal angle and considerably broader than in *cassiae L.* Hindwing with a short, narrow, light yellow admarginal band, terminating at the upper median. ♀ with scarcely appreciable red-brown tinge on the hindwing. Under surface: pale grey, the yellowish oblique band of almost uniform colour across the entire forewing. Ocelli of the hindwing, including the anal, very large. This subspecies, which manifests distinctly the dry-season characters, has probably sprung from what was originally a dry-season form, similarly to the East Javan forms which have already attained to fixity as subspecies. It is fairly certain that in the other northern provinces of Brazil, some of them with still more sterile conditions and even longer rainless periods than prevail in Bahia, still more specialized *cassiae* races occur. — **decentius** *Fruhst.* forms the transition from *pudicus* to the Central and South Brazilian local form *lucullus*. Bands as in *pudicus*, but dark orange-coloured. Under surface: ochreous band of the forewing short, broad, extending from the anal angle only to the middle median, at the lower median deeply notched by the black basal colouring.
- lucullus**. *Minas Geraes.* — **lucullus** *Fruhst.* (61 a) differs from all the northern races in having the under surface considerably darkened, with all the whitish and yellowish parts standing out more distinctly, especially on the hindwing. The striation is almost deep black and the purple tinge is increased in extent and intensity. ♂: band of the forewing dark ochreous, costally very broad, proximally very irregular, i.e. deeply incised, anally narrowing as in HÜBNER's fig. I, pl. 74. Admarginal band of the hindwing in contrast to *pudicus* and *decentius* little developed, only consisting of 2 or 3 diffuse patches. ♀: transverse band of the forewing much enlarged, broader and paler than in typical *cassiae*, proximally irregular. Admarginal band of the ♀ very broad and long, always distinct and remaining light yellow as far as the middle median. Anal area tinged with red-brown. Under surface; ♂ with the yellowish anal band of the forewing quite narrow, obsolete. ♀: band very broad, light yellow to the second median, then somewhat covered with reddish scales, running to the costal margin and becoming gradually paler. Ocelli of the hindwing very large. The butterfly is common at Rio among banana, on the leaves of which the light green larva lives. Espiritu Santo, Rio de Janeiro, São Paulo and especially common also at Blumenau, in Santa Catharina; also in Paraguay, but very rarely. — **castaneus** *Stich.* Upper surface very dark; oblique band continuous to the lower median vein, then broken up; hindwing unicolorous. Under surface very bright, with large eye-spots. ♀ larger, almost as in typical *cassiae*, but the markings at the distal margin of the hindwing indistinct. Specimens sometimes occur with the band of the forewing much lighter and abbreviated, recalling *tamarindi*. Central America and Colombia. — **rubigatus** *Stich.* Forewing of the ♂ somewhat broader, apex less pointed, the band generally as in the typical subspecies, occasionally somewhat widened, posteriorly complete to the extreme end, or here sometimes indistinct. Hindwing with some small apical spots, which are sometimes continued as washed-out rust-red crescentic spots at a short distance from the margin. Hinder angle behind the cell more or less tinged with dark rust-red. Otherwise like typical *cassiae*; the form shows all transitions to this. From Coca in Ecuador. — **strophios** *Fruhst.* Band of the hindwing mostly at some distance from the distal margin, prolonged nearly or quite to the anal angle, much as in the typical *cassiae* ♀. Likewise connected by transitions with the neighbouring forms. Coroico in Bolivia.
- zelotes**. **O. zelotes** is split up into 2 local races: **zelotes** *Hew.*, from Colombia. ♂ above dark brown, forewing

oblique band; this is of medium breadth, on the inner side rectangularly bent posteriorly, terminating in a point just before the median vein. In the apical area 3 small white spots. ♀ unknown. — *zelus* *Stich.* Shape *zelus.* of *O. cassiae*, but somewhat larger, the apex of the forewing pointed. Upper surface dark brown, beyond the cell of the forewing a sharply angled band placed as in the typical subspecies, but broader, fuller-margined, posteriorly tapering to a point not far from the distal margin directly before the submedian. In typical *zelotes* this band is rectangular on the inner side, here only obtusely curved, but its peculiar position affords a characteristic and unmistakable distinction from *O. cassiae*. Equally unmistakable are the differences on the under surface. It shows in the forewing a grey-brown basal and cellular area with simple, undulate transverse lines, arranged in peculiar figures, in the anterior part of the distal area a triangular patch with very fine transverse striation. The hindwing has a strong violet tone and is quite finely watered with blackish wavy lines and whitish shading. Scent-organs as in *O. cassiae*. Type: 1 ♂ in coll. STAUDINGER. Panama: Chiriqui.

O. tamarindi extends northwards to Mexico, otherwise its area of distribution coincides with that of *O. cassiae*, but the geographical branch-races differ more considerably, so that many forms from the Andean region are further removed from the name-type. The synonymy of the branch-races has not yet been satisfactorily cleared up, as neither the earlier authors nor STICHEL and myself observed that **tamarindi** *Fldr.* *tamarindi.* (= *xiphos* *Fruhst.*) (61 b) came from Venezuela, and so it comes about that a more northerly race differing considerably from *tamarindi*, and which I now call **sikyon** subsp. nov. (still figured, 61 b, under the old name *sikyon.* *tamarindi*) passes as *tamarindi* and was also figured as such by GODMAN and SALVIN in the celebrated *Biologia Centrali-Americana*. Our figure of the ♀ is defective as regards the hindmargin, and an extended red-brown tinge on the upperside of the hindwing is not brought out. In the ♂ the upper surface is dark brown, the distal margin anteriorly grey-brown. Band of the forewing dirty white, in its posterior part sometimes brownish, anteriorly of approximately uniform breadth as far as the middle median vein, on the veins somewhat incised on both sides, then constricted or narrowly interrupted by the middle median and the submedian, thus posteriorly broken up into two spots, the second placed at the margin of the wing close to the hinder angle, as an elongate, curved point. Hindwing with a lighter patch or spots at the apex, dirty white or brownish, and from there onwards with a dull rust-red posteriorly washed-out, narrow undulate or curved band near the margin. Anal area beyond the cell, about between the submedian and the upper median vein, more or less strongly tinged with rust-red. Anterior eye-spot on the under surface ovalobliquely placed, distally obliquely flattened, only narrowly margined with black-brown. ♀ larger, with broader wings, apex more obtuse. Band of the forewing whitish as far as the posterior point, broader and more complete. Light patch in the apex of the hindwing more distinct, becoming almost a band, the adjacent undulate line near the margin better developed. ♂ type from Tepic, West Mexico. Type of the ♀ from San Pedro Sula, Honduras, in coll. FRUHSTORFER. *sikyon* was also recorded by GODMAN from Orizaba and other places in Mexico and said to be distributed throughout the whole of Central America to Colombia. — **kleisthenes** *Fruhst.* is the brilliantly coloured continuation of *sikyon*, from which it is distinguished by the more intensive velvety brown tinge in the basal area of the forewing and the dark chestnut-brown discal part of the hindwing. The forewing bears further a more compact, lighter yellow transverse band of almost uniform breadth and the hindwing has a broad terminal border, anteriorly light gold-yellow, posteriorly reddish. Under surface paler, more washed-out than in *sikyon*, more brown-yellow instead of grey-black. The yellowish subanal band of the forewing more strongly marked, broader, more pronounced in colouring. Anal ocellus of the hindwing with light brown foreground. Collected in September on the road to the Quindiu Pass, West Colombia, at about 1500 m. — **cherocles** *Fruhst.* *cherocles.* closely approximates to typical *tamarindi* *Fldr.* from Venezuela, as we frequently observe in species from eastern Colombia, but *cherocles* is sharply distinguished from the name-type by the presence of a distinct, moderately broad and only short marginal band on the hindwing, of reddish ochre-yellow colour, extending from the upper radial to the upper median. The transverse band of the forewing is narrower, deeper ochre-yellow, strongly narrowed at the middle median, the adjacent but well isolated spot more wedge-shaped; under surface darker than in Venezuelan specimens, the anal band more ample, somewhat more vertical. Upper Rio-Negro, East Colombia, discovered by A. H. FASSL at 800 m. ♀ with light ochre-yellow transverse band on the forewing. Hindwing with broad ochreous distal border, running as a band to the upper median and from there to the anal angle as a subterminal undulate line. Hindwing beyond the cell with a dark rust-red area. — **corrosus** *Stich.*, in *corrosus.* my collection represented by three examples, has a somewhat narrower band on the forewing than in our figure of *xiphos*, of dirty white to pale brownish colour, commonly abbreviated and narrowed posteriorly. Hindwing unicolorous chestnut-brown. ♀ not differing materially from that of *sikyon*. Ecuador, not very rare. f. **spadix** *spadix.* *Stich.* has the band of the forewing narrow, partially broken up into spots, brownish instead of white-yellow. Singly among the normal form. Balzapamba, Ecuador, in July. — **incolumis** *Stich.* The wings broader. The *incolumis.* oblique band of the forewing narrowed in the cell by tooth-like indentations of the ground-colour, much as in *quiteria*, but in the ♂ chalk-white and towards the anal angle more strongly narrowed and terminating in a point at the submedian, in the ♀ light yellowish. Also on the under surface the band of the forewing is pure white; anterior eye-spot of the hindwing smaller than in *bogotanus*. In my collection from Pozuzo, Peru and from Bolivia. — **terenzius** subsp. nov. is based on the figure of a ♀ given by STAUDINGER in the *Exotic terenzius.* Butterflies 1888 pl. 72, which came from Santa Catharina, where Dr. FRITZ MÜLLER also found the larva men-

tioned in the description of the genus. The ♀ differs from that of *sikyon*, which it closely resembles, in the white median band of the forewing terminating at the lower median; under surface of the forewing costally less, anally more broadly tinged with white than in Mexican examples.

bogotanus.

O. bogotanus inhabits Colombia. Imago very large, above nearly black, velvety, with dull purple gloss. Transverse band narrower than in *sikyon*, composed of separate, nearly white spots, which in their turn are again dusted with purple. Hindwing with the hair-pencils which are also so characteristic of *tamarindi*: a very broad, bushy one beyond the praecostal cell, a somewhat smaller one before the apex of the cell and a third, of yellowish or blackish hairs, in the bare friction-patch of the inner margin. Under surface especially brilliant, the subapical part white, basal area sharply contrasting with it, dark cocoa-brown. Apical ocellus of the hindwing unusually large, almost suggesting those of the *Caligona*. Two local forms: **bogotanus** *Dist.* Type probably from Muzo, as the species scarcely seems to ascend above 1000 m.; very large with the distal margin of both wings boldly projecting. Forewing with a whitish, purple-edged oblique band, composed of irregular, isolated spots not placed in regular alignment. Under surface of the hindwing predominantly light brown. — **phrata-phernes** *Fruhst.* was recently discovered by FASSL, is smaller than the name-type and presents a melanotic extreme of the collective species; a phenomenon which is paralleled in *O. quiteria* from the same localities and which we also observe in *O. tamarindi*, of which the brightly coloured branch inhabits the West Cordilleras (*kleisthenes* *Fruhst.*), whilst the dark (*cherocles*) occurs together with *phrataphernes*. ♂ with the band of the forewing dull yellow, narrow and more uniform. Ground-colour deeper black than in Muzo examples. ♀ with relatively narrow white transverse band on the forewing and a distinct marginal border on the hindwing, but scarcely more than 1 mm. in breadth, which is anteriorly whitish, posteriorly yellowish, and terminates at the lower radial. Under surface of the ♂ with yellowish instead of white band on the hindwing; in the ♀ the band is broader and chalk-white. Apical ocellus of the hindwing somewhat smaller than in *bogotanus*, more quadrate instead of oval. The striation of the median part more delicate and placed on a darker ground than in *bogotanus*. Upper Rio Negro, from elevations of 800 m. *O. bogotanus* was treated by STICHEL as the Colombian branch of *O. tamarindi*. But the discovery of two actual local forms agreeing in habitus with *O. tamarindi*, one of which even flies together with *bogotanus phrataphernes* in the same localities, removed the last doubt as to the specific status of this *Opsiphanes*, which already differs from *tamarindi* in its size. The egg of this beautiful Brassolid is somewhat larger than that of *Sphinx ligustri*, elongate-rounded, cream-yellow with fine longitudinal grooves. The larva nearly approaches the long known *tamarindi* larva, is merely of a lighter green and with 2 (*tamarindi* 1) dorsal lines of a less glaring red. Food-plant: holly. The cremaster of the pupa is strongly curved proximad and the forewing-case has the inner margin projecting acutely, which gives the chrysalis a boat- or rather gondola-shaped appearance; it is of grey-green colour. As with most Brassolids the eggs are laid readily even in captivity, and in good numbers. I believe that in future attempts to breed South American butterflies in temperate climates the Brassolids will take the first place. For besides the circumstance just mentioned two other factors of importance have to be considered. The food-plants (species of banana and palm) thrive very well even in quite temperate climates if taken care of and protected from frost, and the plants are propagated not primarily by seeding, but most rapidly and abundantly by suckers. Moreover, the insects do not pair in the sunshine, as in most other families of Diurni, but during the flight of the butterflies in the evening and morning twilight (FASSL).

O. quiteria is one of the most widely distributed species of the genus and is met with from Central America to Bolivia and on the Atlantic side from Guiana to Paraguay and Santa Catharina. In the most northerly race the sexes are dimorphic and the Colombian subspecies differ strikingly from the name-type. Larva green sprinkled with white dots, lives on palms. — **quirinus** *Godm.*, described from Guatemala, in my collection from Honduras, extends as far as Panama, but is considered very rare. ♂ above with an ochreous band posteriorly lost in the ground-colour and two very large white subapical patches. Hindwing predominantly red-brown with traces of a yellow band between the radials. ♀ with white transverse band on the forewing, hindwing entirely chestnut-brown, before its terminal margin with three rounded yellow spots between the radials. — **quiteria** *Cr.* (61 b), originally described from Surinam but also known from the Lower Amazon, has the ochreous band on the forewing of the ♂ broader than in *quirinus*. The ♀ varies only inconsiderably in the extent of the short subcostal band on the hindwing. — **obidonus** *Fruhst.* (62 d), the form from the Middle Amazon, differs from *quiteria* from Surinam as follows: ♂ with the yellowish oblique band on the forewing narrower, submarginal band of the hindwing longer and narrower. ♀ with the half-band on the forewing more sharply incised proximally and distally; submarginal band of the hindwing narrower, and sharply expressed as far as the 1st median vein; the anal area broadly suffused with red-brown nearly to the cell. Obidos, August and September. Coll. FRUHSTORFER. — The race from the Upper Uaupes may be introduced as **mylasa** *Fruhst.* and is at once conspicuous by the much widened, orange band on the forewing. The yellowish ante-marginal band of the hindwing is entirely obsolete anteriorly and only marked by 3 obscure round dots of the size of a pin's head, but below the second median is continued to the anal angle as a slightly glossed, narrow,

sharply defined stripe. *mylasa* forms the transition from *quaestor* Stich., found on the eastern slopes of the Andes in Ecuador, to *obidonius* Fruhst., and from this to the name-type from Surinam. The hindwing in *mylasa* appears rounder, less dentate than in the other *quiteria* forms, and the yellowish band of the forewing is narrower than in *quaestor*. — **augeias** Fruhst. A strikingly light geographical subspecies without near allies. *augeias*. ♂ best compared with *O. badius* Stich. from Muzo, but the shape of the wings still more uneven, more undulate. Band of the forewing broader than in *badius*, yellowish, with a slight tendency to whitish. Basal area less rust-red than in *badius*. Hindwing nearly chestnut-brown, with the exception of a black undulate distal border and a black transcellular area. From the costal to the upper median vein runs a quite vertical, light ochre-yellow band of medium breadth, composed of three fragments. ♀ on the whole like the ♂, the transverse band of the forewing white, slightly inclining towards cream-colour, the subapical band of the hindwing continuous, broader and paler yellow than in the ♂. Hindwing lighter rust-brown, the black area somewhat washed-out and reduced. Under surface approaching that of *quirinus*, but distinguishable at once by having the band of the forewing broader and lighter yellow in the ♂♂ and posteriorly more diffuse in the ♀♀. From the Rio Aquaca Valley in the West Cordilleras, Colombia, at about 2000 m. — **phylas** Fruhst. In this *phylas*. pronounced local form the differentiation has proceeded further than in *augeias* and one might be tempted on account of the markings of the upper surface to regard it as a separate species were it not that the character of the underside demonstrates its identity. ♂ above black. The red-brown parts of *augeias* changed into an extremely characteristic grey-black colour, otherwise entirely unknown in the genus, but standing out little from the deep black ground-colour. Band of the forewing shorter than in *augeias*, only reaching to the lower median, narrower and of a dark straw-yellow slightly clouded with grey at the edges. Hindwing only with two remnants of an obsolete yellowish subapical band. ♀ recalling that of *O. badius*, the forewing bearing a very broad, nearly cream-yellow transverse band, which, however, is more regular and between the medians more extended. Hindwing with three isolated subapical patches, which are strongly marked, although less so than in *augeias* ♀. Ground-colour somewhat duller than in the ♂, uniformly black with dull brown reflection. *phylas* consequently forms the melanotic extreme of the collective species as it occurs in Colombia, but there is no connecting-link known with the Amazon races as, say, in the East Colombian *Eryphanis*. Under surface likewise darker than in *augeias*. ♂ with shorter, deeper yellow transverse band on the forewing, in the ♀ considerably broader, particularly between the medians, where it becomes cream-coloured with a slight purple gloss, but towards the costal margin changes into a chalk-white area delicately irrorated with black. Hindwing dark grey, not relieved with reddish discally and distally as in *augeias*. The darker under surface in conjunction with the broad bands will also at once separate *phylas* from *quirinus*. Upper Rio Negro, East Colombia, 800 m. Collected by A. H. FASSL. By the discovery of these two divergent and highly specialized *quiteria* races the interesting tendency of Colombia to produce parallel, representative, but nevertheless strikingly differentiated forms is again illustrated, and at the same time new light is shed on the unexampled richness of this country in species. The existence of these local races approaching the general *quiteria* type further renders it possible to separate *O. badius* Stich. as a distinct species, just as the discovery of two genuine Colombian local forms of *O. tamarindi* resulted in the specific rehabilitation of *O. bogotanus* Dist. — **quaestor** Stich. Above especially *quaestor*. deep black, only the apex of the forewing slightly lighter. Band of the forewing distally much widened. Hindwing only with traces of a faint submarginal band of reddish spots. Under surface more brightly shaded. 1 ♂ from Coca, Ecuador. — **bolivianus** Stich. has the ground-colour of the upper surface lighter, the band *bolivianus*. darker, reddish brown. Hindwing with distinct macular band before the distal margin. Nearest to *meridionalis*, but distinguished by the broader, darker band on the forewing. Bolivia. — **quirinalis** Stgr. Band of the *quirinalis*. forewing bone-yellow to ochre-yellow or nearly white, slightly dusted with brown; hindwing above with 2 or 3 whitish or yellowish spots at the apex, or sometimes with a reddish submarginal macular band. Peru, Ecuador, west of the Andes (?). — **philon** Fruhst. (61 c). The differences which *philon*. are shown in *obidonius* become still more pronounced in *quiteria* from Espiritu Santo, the most beautiful geographical form yet known. The deviation from the type from Surinam consists in: (♂) hindwing less undulate, upperside of abdomen and entire basal part of hindwing with long dark brown-red hairs, much as in *quirinia* Godm. from Central America. Submarginal band of the hindwing continued as far as the 3rd median vein, lighter yellow-brown, more sharply defined, in the anal angle broadly and diffusely dark red, confluent with the red basal colour. Under surface: much darker, more copiously shaded with black, especially in the cell of the forewing. Anal and distal areas of the hindwing commonly with a violet tinge. The white, slightly diffuse spot below the submedian of the forewing reduced. ♀: the yellowish band of the hindwing sometimes continuous to the anal angle, at least twice as broad as in the ♂, anally even wider, brilliant red-brown, the red shade reaching the cell. Espiritu Santo, Rio de Janeiro. As a sort of satellite of *philon* there occurs with it also what may be called an analogous, mimetic race of a second species, namely of *invirae* Hbn., which by the deeply incised and unusually broad yellowish bands on both wings forms at the same time the most strongly marked of all the *invirae* forms. — **meridionalis** Stgr. ♂ always smaller than *philon*, forewing *meridionalis*. with the apex less pointed and the distal margin more shallowly excised than in *quiteria*. Oblique band in this form somewhat variable, sometimes terminating in a very sharp, sometimes in an obtuse point. In the distal part of the cell occasionally a blurred yellowish patch. Hindwing with the distal margin less dentate,

although still strongly undulate (particularly at the median veins), near the distal margin with complete band, well developed to the hinder angle, its posterior part more or less shot with reddish, somewhat weakly coloured; there is also a faint rust-red tinge in the part of the wing which adjoins this anteriorly. ♀ of the same shape as the preceding subspecies, as a rule with the ground-colour somewhat paler, forewing not essentially different, the hindwing near the distal margin with a very broad band, which is anteriorly pale to red-yellow, from the middle onwards changes gradually into a bright rust-red and posteriorly is diffused into a large, vaguely defined rust-red area, gradually shading into the ground-colour. Forms transitions to the preceding race. Larva cylindrical, thickened in the middle, green, sprinkled with white dots, further with dark dorsal and lateral lines and stripes and yellow stigmata. Head yellowish, brown-striped, with reddish horns. Anal end with long tail-fork. Lives on palms. (According to BURMEISTER, *Pavonia quiteria*.) *meridionalis* differs from *philon*, apart from its smaller size, chiefly in having the band of the forewing in the ♂ broader and paler yellow, in the ♀ narrower and more sharply defined. The hindwing has the anterior part lighter and the anal area clearer red-brown than in *philon*, also the general colouring of the under surface is always paler, more washed out, with the submarginal area predominantly yellow, hence more gaily coloured than in more northerly forms. The yellow oblique band on the forewing beneath appreciably narrower than in *philon*, also in the ♀. Santa Catharina, probably also in Parana; not yet observed in Rio Grande do Sul. In São Paulo and Paraguay on the other hand transitions occur and the examples before me approximate to *philon* in the deep colour of the under surface, to *meridionalis* in the narrow band on the forewing beneath, and differ from both in the more extended and much darker chestnut-brown tinge of the anal area on the upperside of the hindwing. If this race is constant it might be called *oresbios subsp. nov.*

oresbios.
badius.

C. badius Stich. Hindwing strongly dentate. Band of the forewing contracted into a narrow yellowish white macular band. This is placed close to the cell, touching its posterior angle, but is anteriorly more or less indistinct as far as the subcostal and runs obliquely nearly to the distal margin at the lower median vein. Sometimes it is prolonged beyond this into a curved point at the hinder angle. Hindwing without spots and bands, but strongly tinged with rust-red in the anal and basal area. Under surface very brightly marked and differing from the preceding subspecies only in the narrower band of the forewing. The ♀ (hitherto unknown) is considerably larger than the ♂. Forewing predominantly black, only towards the base slightly tinged with rust-red — the pure white oblique band about three times as broad as in the ♂; hindwing deep rust-red with narrow black terminal border. ♂ very similar to *quirinus* Godm. ♀, however, larger. Band of the forewing more broken, hindwing above without the subapical rudiments of a yellowish band. The white transverse band on the underside of the forewing considerably broader even than above, also more extended than in *quirinus*. *badius* was united by STICHEL with *quiteria*. But the discovery of two further races more nearly allied to *quirinus* makes it seem advisable to raise this form, which is strikingly different in the ♂, to specific rank. Locality Muzo, 400—800 m., Colombia.

camena.

C. camena Stgr. Dark brown. Basal area paler brown, apical part black-brown. Distally to the cell runs a narrow ochre-yellow macular band, which is anteriorly closed and obliquely placed, sharply angled in posterior direction on the lower radial, and broken up into separate, irregular spots standing in the interneural spaces. It terminates in a double spot in the hinder angle, immediately before the submedian. Near the apex there is a small white double spot and behind it a somewhat larger white spot. Under surface pale brown with dentate and curved lines, which form irregular darker figures. Near the apex the three small white spots of the upper surface, between the radials a black, yellowish-ringed eye-spot finely bordered with black-brown. Distal area brown, posteriorly yellowish, near the margin two dentate lines, which disappear towards the hinder angle. Hindwing with the distal margin strongly undulate, with ochre-yellow lunular spots and a row of curved or lunular spots of the same colour near the distal margin, as well as the two hair-pencils, in the cell and at the submedian, characteristic of the group. Under surface pale brown. Anteriorly, somewhat beyond the middle of the costal margin, a large, oval, obliquely placed eye-spot, which is proximally clouded with brown, bears a white curved streak and is margined with black-brown. A second, rounded eye-spot beyond the cell near the hinder angle is black, dusted with yellowish, anteriorly edged with white, ringed with yellow-brown and finely margined with black-brown. Costal margin strigulated with white. Across the cell runs an irregular brown transverse band; base of the wing dark brown. The rest of the wings clouded, striated and marbled with black-brown. Not far from the distal margin there is a row of lunular spots composed of very dense striation, showing up lighter against the darkened distal border. ♀ larger than the ♂, apex of the forewing less produced, subapical patches purer white, all the ochre-yellow bands strikingly widened and lighter, particularly on the forewing, basal area and cell of the forewing as well as the whole upper surface of the hindwing rust-red. The black submarginal band of the hindwing bordered with ochre-yellow on both surfaces. Forewing beneath with broad whitish, purple-tinged transcellular area, the submedian area broadly ochre-yellow to the base. Hindwing lighter brown with lighter bordering to the ocelli than in the ♂. Colombia, West Cordillera, Rio Aguaca Valley, about 2000 m. According to FASSL the egg is similar in size and shape to that of *O. bogotanus* Dist.; it is merely more green-yellow and less transparent; the longitudinal grooves have sharper edges. He more than once observed the eggs laid on the underside of the leaves of a species of palm with non-feathery fronds of a metre in length, in groups of 4—12, arranged in 1 or 2 rows, regularly one beside another. Whilst *bogotanus* inhabits

the lower mountains regions together with *Caligo epimetheus*, *camena* shares its area of flight with *Caligo oberthueri* in the untrodden marshy primeval forests of the higher mountain districts. FASSL several times observed *camena* ♂♂ shortly after sunset at places where cattle were feeding; they would suddenly run for a short distance on the short turf, then rest on a piece of cow-dung for a moment with the antennae raised high, digging greedily into it with the proboscis, the next moment again running a short distance and repeating the same performance; at the same time they are extremely shy and fly away even when cautiously approached before one can get near them. The very rare and much larger ♀ has the ground-colour entirely chestnut-brown, possibly hitherto quite unknown and undescribed (FASSL).

O. sallei approaches *quirina* and splits up into four geographical races, all more or less rare. — **sallei** Westw. is dark brown; forewing at the base slightly tinged with reddish. Transverse band complete to the upper median vein, there strongly bent distad, afterwards broken up into spots; the last is small and pointed, following the curve of the hinder angle and terminating at the hindmargin. On the under surface the separate spot in the middle median cellule occupies the entire breadth of this and is slightly connected with the transverse band distally. Hindwing with rather broad distal band, notched on the veins and gradually displaced at the lower radial, anteriorly light ochre-yellow, darkened from about the upper median vein, towards the hinder angle becomes rust-red and is anteriorly widened but ill-defined. Venezuela, Colombia. — **mutatus** Stich. Band of the forewing broader, somewhat darker reddish ochre-yellow, smooth for its whole length or in the upper median cellule only obtusely indented proximally the connecting spot, however, anteriorly adjoining the anterior part of the band for its entire breadth, posteriorly completely connected with the following band-spot or only separated by the vein. In the distal part of the cell sometimes an obscure brownish spot. Hindwing near the distal margin with considerably narrowed band, which mostly terminates at the upper median; when longer it is gradually lost in the ground-colour as a vague reddish clouding and becomes narrower, instead of widening and becoming diffuse. The distal margin somewhat less dentate. Ecuador. — **farrago** Stich. ♂ with somewhat paler ground-colour, basal area of the forewing tinged with dull rust-red. Band of the forewing as in the preceding subspecies. Band of the hindwing much widened (as much as 4—5 mm.), less notched at the sides than in the typical subspecies and distinctly expressed as far as the lower median vein, but before that already somewhat clouded with reddish, at its termination in the hinder angle rust-red, ill-defined and anteriorly diffuse, so that the hinder angle and basal area of the wing appear predominantly pale rust-brown. Under surface weaker marked, the striation of the hindwing in particular less sharp, the ground-colour lighter, whitish-brown. The separate yellow spot in the middle median cellule of the forewing smaller, oval, quite isolated, a character which, however, must not be considered as distinctive. Southern Peru, Bolivia. — **nicandrus** subsp. nov. Distinguished from the preceding races by the considerably narrower red-brown band, which is broken between the median veins into separate crescentic spots. Upperside of the hindwing scarcely appreciably tinged with rust-red. Underside of the hindwing much darker brown, with purple, more dusky tinge. Coroico, 1200 m., Bolivia.

O. invirae occurs everywhere together with *quiteria* and must be regarded as a slightly differentiated species, which in its southern offshoots can scarcely be separated from the southern races of *quiteria* Cr. and in its northern forms, at least on the under surface, is not distinguishable from *cassina* Fldr. Yet the larvae probably differ decidedly; according to BÖNNINGHAUSEN they are more unicolorous than those of *quiteria*, which bear bright-coloured stripes. Feed on palms. — **relucens** Fruhst. ♂: similar to *remolius*, but smaller. Band of the forewing broad, light ochreous, strongly curved and extending to beyond the submedian in almost uniform breadth; its posterior spot sharply defined, rounded. Band of the hindwing anteriorly yellowish, from the upper median vein onwards rust-red and distinctly defined, reaching to the hinder angle, but narrow and uniformly deeply notched distally. Under surface in the type-specimen with broader yellow band on the forewing and larger eye-spots than the typical subspecies; between the eye-spots a chain of 4 whitish grey crescentic spots. Length of the forewing 36 mm. Honduras (San Pedro Sula). — **cuspidatus** Stich. ♂: forewing with very pointed apex. Distal margin very narrowly bordered with grey. Band of the forewing only complete to the lower median vein, beyond this sometimes a further small obsolete terminal spot. Basal area reddish grey. Band of the hindwing very narrow, darkening to rust-red at the radials and gradually disappearing. Anal area slightly tinged with reddish. From the Volcan de Chiriqui. — **invirae** Hbn. ♂ with narrow band on the forewing, the proximal margin of which is not at all or only very little produced into a tooth behind the cell; at the middle median vein it is somewhat displaced at both sides and at the lower median slightly constricted. For the rest it is rather sharply defined and smooth; the posterior part of the band bends in a curved, pointed hook in the hinder angle towards the hindmargin and mostly extends beyond the submedian, although less distinctly expressed. The eye-spot near the apex and the anterior part of the lines near the distal margin on the under surface showing through rather distinctly. The band near the distal margin of the hindwing narrow, sometimes almost broken up into spots and abbreviated, occasionally extending to the hindmargin, dull rust-red. ♀ larger, paler; forewing more elongate, distal margin less excised. Band of the forewing pale ochre-yellow, lighter anteriorly than posteriorly, broader than in the ♂, behind the angle of the cell distinctly produced into a tooth, at the median veins less displaced or constricted. Band of the hindwing broader, but mostly duller, in the posterior part suffused with reddish brown without distinct demarcation, much as in *O. quiteria meridionalis*.

Distinguishable from the latter, apart from its smaller size, chiefly by the undulate distal margin of the hindwing, the finer striation on the under surface and the more pointed apex of the forewing. Guiana, northern Brazil, Venezuela. — **ledon** *subsp. nov.* forms a transition from *invirae* Hbn. to *intermedius* Stich. from the Upper Amazon and differs from the name-type in its larger size and the darker oblique band of the forewing, which is narrowed towards the costa, and posteriorly runs out into quite a narrow point. Lower Amazon. — **intermedius** Stich. is larger, band of the forewing much widened, of a somewhat darker reddish ochre-brown colour, proximally with a strongly projecting tooth, at this point 8 mm. in breadth, at both sides without or only with very slight notches on the veins, towards the end rapidly narrowed, terminating in a sharp point. The band is thus nearly straight to beyond the submedian and only somewhat curved at the posterior end. Band of the hindwing narrow, anteriorly of an indefinite ochre-yellow, almost broken up into loosely connected spots, towards the hinder angle rust-red and more continuous, but ill-defined. Under surface more brightly coloured, but the striation fine and regular. Upper Amazon. — **sticheli** Rüb. has the band of the forewing in the ♂ light ochre-yellow, posteriorly pretty uniformly narrowed, between the upper and middle median veins incised; it terminates in a small elongate spot before the submedian. Band of the hindwing anteriorly marked by three separate small yellowish spots; it widens at the lower radial into dull rust-red, connected, crescentic spots and is diffused in the hinder angle. Somewhat variable in the composition of the band on the hindwing and the breadth of that on the forewing and in general very similar to the typical subspecies. The hitherto unknown ♀ approaches *amplificatus* Stich. from Paraguay; band of the forewing somewhat narrower, more strongly dentate proximally between the medians, of somewhat more reddish yellow colour. On the hindwing the three subapical anterior spots stand out more distinctly from the posterior bright rust-red part of the band, which is more broadly diffuse anally. Under surface darker than in *amplificatus*, approximating more to that of *remoliatus* Fruhst. in the deep ochre-yellow anal band on the forewing. Colombia, type probably from the Cauca Valley, both sexes also found by FASSL on the Upper Rio Negro at about 800 m. — **amplificatus** Stich. is a typical Paraguayan butterfly, of small size, smaller than *remoliatus*, with somewhat lighter ochre-yellow band on the forewing, and more closely and sharply dentate submarginal band on the hindwing, ♀ with predominantly yellow transverse band on the forewing and paler, posteriorly only inappreciably red-brown submarginal area. Under surface strikingly pale. Ocelli smaller than in *remoliatus*. Paraguay. — **remoliatus** Fruhst. (61a ♂; ♀ 61a as *meridionalis*). ♂: small apical spots yellow instead of white. ♀: apical spots larger and purer white. Transverse band of both wings darker ochreous, more sharply defined especially in the proximal part, and the band of the hindwing in the ♂ costally narrower, anally broader, darker rust-red. Distal border of the hindwing more broadly black, wings still less excised. Under surface with darker hatching, ocelli larger than in *amplificatus*. Larva on *Giriva* leaves, where it is difficult to find on account of its green colour. Pupates in November or December and again in June. The pupa is light green with a golden dot at each side. The butterfly emerges after 20—30 days; it is mostly common and hides among palms. ♂ type from Santa Catharina, ♀ type from Rio Grande do Sul. In the latter province *remoliatus* is by far the commonest species of *Opsiphanes*. According to 12 ♂♂ and 10 ♀♀ in coll. FRUHSTORFER it is very constant, varying only inconsiderably in size and not at all in colouring. — **agasthenes** Fruhst. differs from *amplificatus* Stich. in its larger size; much darker colouring; oblique band of the forewing in 2 examples deeply incised beyond the cell as in *quiteria*, band of the forewing behind the cell with unusually strong teeth; band of the hindwing rather narrow, sometimes almost like a string of pearls, but posteriorly widened and rust-red. Under surface much darker, all the ocelli larger and more broadly ringed with black. **rectifasciata** Fruhst. is an aberration in colour markings. Band of the forewing narrower, darker ochre-yellow, running almost rectilinearly, i. e. neither proximally nor distally considerably incised. Peru: Pozuzo. — **isagoras** Fruhst. In accordance with its geographical position *isagoras* approximates more to *amplificatus* Stich. than to *agasthenes*. It differs from both: in the more ample transverse bands of the forewing, deeply incised proximally, recalling *quiteria*, and the extended submarginal bands of the hindwing, which are especially strongly widened costally and are anally lighter red than in *androsthenes*. Beneath the forewing is lighter, the hindwing darker than in *amplificatus*; the anal ocellus of the hindwing larger, more oblong. Bolivia: Cochabamba. — **pseudophilon** Fruhst. (61d ♀). Habitus about as in *amplificatus* Stich. from Paraguay. Yellow band of the forewing strongly curved, particularly beyond the cell. Band of the hindwing light yellow to the upper median, then much widened, as a dark brown continuation, but sharply defined to the anal angle. Both the yellow and the red-brown section of the band distally much more deeply incised than in any other *invirae* form. In the cell of the forewing in the ♀ near the apex the beginning of a reddish yellow patch. Espiritu Santo.

O. cassina cannot be separated beneath from *O. invirae* by any very salient character, but may be easily known above by a mostly complete, nearly quadrate, ochre-yellow or rust-red spot before the apex of the cell of the forewing. *cassina* is at the same time confined more to the northern part of the range of *invirae*, it extends indeed on the Andean side parallel with *invirae* and *quiteria* as far as Bolivia, but on the Atlantic coast it probably does not reach beyond the Lower Amazon and so far as our present knowledge goes is already wanting in Central Brazil. It would appear that the dry climate of the provinces of Piahy, Ceara and Bahia, which, however, are practically unexplored, stands in the way of its spreading in this direction. — **fabricii** Bdv. (61d), previously known from Guatemala to Panama, was quite recently sent to me also from Tepic, West Mexico. The ♂♂ of this subspecies are mostly small with the apex of the forewing but little pointed,

the distal boundary of the distinctly forked band little or not at all constricted. In the ♀♀ the proximal forked part is mostly obsolete in the cell, the colour of the cell itself ferruginous. Hindwing only in the anterior part with ill-defined submarginal band, this fades out between the radials, changing into rust-brown and grey-red, and this colour spreads over almost the whole surface of the wing, starting from the anal part. The form recurs in Colombia and western Ecuador with trifling modifications, the ♂♂ are on an average somewhat larger and more brightly coloured, without, however, any specific distinguishing marks being recognizable. The distribution of *O. c. fabricii* may therefore be accepted as given above. — **chiriquensis** *Stich.* seems to occur *chiriquensis.* exclusively at the Volcan de Chiriqui, Costa Rica. Of considerable size, ♂ with the apex rather pointed and the distal margin of the forewing strongly convex posteriorly. Band of the latter very broad throughout, bright rust-yellow, distal boundary but little constricted, in this respect almost agreeing with *fabricii*. Fork distinct, proximal part broad in the cell, narrowly connected with the main band. Costal margin of the hindwing broadly reddish to the upper radial, particularly at the base and at the apex. Band of the hindwing very broad, broader than in any other form of the species, anteriorly red-yellow, in the middle changing into rust-red, towards the hinder angle widened, without becoming diffuse. Under surface especially bright. ♀ very dark brown, band of the forewing broadly yellowish, fork distinct. Hindwing near the distal margin with broad band, which is anteriorly yellowish, then widened and rust-red, in the anal area broadly diffuse, as in *invirae amplificatus*. — **numatius** *subsp. nov.*, from Colombia without more exact locality, approaches *chiriquensis* in size, but in the *numatius.* shape of the bands more resembles the more southerly *notandus*, differing, however, from both in having the proximal cell-spot of the forewing free and unusually elevated at its distal end. Band of the hindwing much as in the broad-banded *fabricii*, but posteriorly darker rust-red. The under surface also much deeper, darker brown; apical eye-spot of the hindwing more broadly and distinctly ringed with brown than in *fabricii*. — **periphetes** *subsp. nov.*, which may be distinguished from *numatius* by its small size, approaches *merianae* from *periphetes.* Surinam in this as well as in the strikingly narrowed submarginal band of the hindwing, which sometimes disappears altogether at the upper median. It also agrees with *merianae* in having the ochreous transverse band of the forewing considerably narrowed towards both the costal margin and the anal angle. Colombia; more exact locality unknown. — **cassina** *Fldr.*, type in the Tring Museum, was first brought to Europe from the Upper *cassina.* Rio Negro. ♂ comparatively large, length of the forewing 42 mm. Band of the forewing broad, about as in *O. quiteria meridionalis* *Stgr.*, also resembling this in the shape, i. e. distal border without constriction, regularly oblique, directed towards the inner angle. Proximal part of the fork formed by the discocellular obscure and present as an isolated spot. The band of the hindwing rather broad next to the apex, gradually narrowing and changing into a rust-red colour, vaguely diffused at the anal angle. — **merianae** *Stich.* is the form indigenous *merianae.* to Guiana, with distinctly forked band, the ♂ with very pointed apex and strongly convex distal margin to the forewing. This form may be easily and certainly distinguished from all others by the shape of the forked oblique band of the forewing. At the fork the band as a rule projects proximad as far as the angle at the origin of the middle median, its distal boundary is strongly constricted between the middle and upper medians, and it runs into the inner angle essentially narrowed, pointed and somewhat curved. The constriction at the distal boundary and the narrowing behind this constriction are quite characteristic. The submarginal band of the hindwing is moderately narrow, sometimes complete, sometimes reaching only to one-half or beyond it; as a rule it becomes darker brown towards the anal angle, but not rust-red. ♀ similar to that of the preceding form, but smaller, less intensively coloured, the submarginal band of the hindwing not widened in the anal part to the same extent as in that, and not much diffused. — **aequatorialis** *Stich.*, from eastern Ecuador. *aequatorialis.* Similar to the preceding. Forewing with the fork of the band incomplete, the spot placed in the cell, however, is connected posteriorly with the proximally projecting tooth of the main part of the band, only separated by the median. The distal boundary of the band is not essentially constricted, and is as in *cassina cassina*. The band of the hindwing starts close to the apex as a continuous row of ochre-yellow spots, terminates at the upper median vein, there changing to deep rust-red but not diffused; it remains in its whole course approximately uniformly narrow, its posterior part is occasionally blurred. ♀ with the oblique band of the forewing bone-yellow, in the anterior part quite white. The part of the fork placed in the cell is always incomplete and indistinct. Band of the hindwing anteriorly ochre-yellow near the distal margin, changing at the upper median vein into a deep rust-red or red-brown colour; in the hinder angle this spreads out anteriorly as far as the cell. — **notandus** *Stich.* Similar to the preceding subspecies, mostly still larger and more brightly *notandus.* coloured. ♂: main part of the band of the forewing somewhat narrowed distally to the cell, broken, with long teeth on the veins. Hindwing less relieved with reddish at the costal margin, a stripe before the entire length of the subcostal always brown. The band towards the distal margin rather broad, anteriorly paler, posteriorly bright red-brown. ♀: resembling that of *aequatorialis*, the fork in the band of the forewing somewhat narrower, the branch placed in the cell broader and more complete, the distal boundary of the main part more distinctly notched at the veins, the band on the whole somewhat broader, so that the angle at the origin of the upper median vein is entirely filled up (as far as available material indicates). Peru. For the sake of clearness I here recapitulate the range of these three difficult species, which occur together in the following forms:

| | <i>O. quiteria</i> Cr. | <i>O. invirae</i> Hbn. | <i>O. cassina</i> Fldr. |

Group *Catoblepia* Stich.

Differs from *Opsiphanes* chiefly in the secondary sexual characters, the only important structural difference being the narrower cell of the hindwing. A few other details have no generic value, and the group is connected on the one hand with *Opsiphanes* by *O. versitincta* Stich. and on the other with the group *Selenophanes* Stgr. by *O. amphirhoë*. Submedian mostly with felted hairs proximally. Costal and subcostal distinctly though narrowly separated. Subcostal 5-branched, two branches arising shortly before the end of the cell, the first in one case (*O. amphirhoë*) somewhat further proximad, running into the costal margin, the third branch midway between the end of the cell and the apex, the fifth branch forked with the fourth and running into the distal margin. Cell broad, anterior angle rounded, upper discocellular moderately long, continued by the middle one in a gentle curve proximally, the lower oblique, elongate. Median shortly inflated at the base. Hindwing nearly oval, apex rounded. Costal close to and parallel with the costa. Precostal cell broader than long, rhomboid or transverse rhomboidal. Cell narrow, about half the length of the wing. Membrane at the side of the lower median in the ♂ more or less wrinkled close to the cell, the lower median in one case (*O. amphirhoë*) strongly inflated. Cell with a hair-pencil in the posterior part or a hair-tuft in the anterior part behind the subcostal. In all cases at the submedian on a smooth friction-area a smaller hair-pencil, sometimes a brush-like tuft of hairs in or on a fold between submedian and lower median, or with a stripe of long, smooth, distally directed hairs on a mealy area between these veins. Abdomen short and slender, in one case (*O. amphirhoë*) more robust, with a swollen friction-patch at each side.

a) Section *Diophthalmi*.

Underside of the hindwing with two ocelli.

a) ♂ with a hair-pencil before the apex of the cell on the hindwing.

versitincta.

***O. versitincta* Stich.** (66 a) stands in the closest relationship to the species of the group *Opsiphanes* on account of the broad cell of the hindwing. ♂: body above brown, collar and frons red-brown, palpus yellow-brown. Ground-colour of the wings dark brown. Forewing with a deep ochre-yellow postdiscal band, in the apex three small obscure white dots. Hindwing unicolorous. In the cell, close to the median, a long hair-pencil, a brush-like tuft of hairs projecting from a fold before the submedian, a small hair-pencil on a scaleless friction-patch behind it. Under surface brown, forewing in the distal half striated with whitish, the band of the upper surface vaguely indicated by a lighter tone of colour. Between the radials a black, yellow-ringed, apical eye-spot with white pupil. Near the distal margin and parallel with it two black, slightly dentate submarginal lines, somewhat incurved below the eye-spot, the proximal one slightly bordered with orange-yellow for its whole length. In the cell three ill-defined undulate transverse lines. Hindwing striated with white with the exception of the grey-brown distal margin. Length of the forewing 43 mm. ♀: larger, brown, shot with delicate violet except at the apex of the forewing, most strongly at the base. Band of the forewing broader, lighter, proximally running through the end of the cell, at the anal angle somewhat pointed. In the black-brown apex three small white spots. Under surface as in the ♂, but lighter and with a yellowish tone. Length of the forewing 49 mm. Only 1 ♂ and 2 ♀♀ from Surinam and 1 ♀ from Cayenne known.

b) ♂ with a hair-pencil in the cell of the hindwing.

O. xanthus bears especially conspicuous hair-brushes at the submedian and a tuft of very long hairs in the cell of the hindwing. Three well differentiated local races, of which the most southerly *xanthus*, in particular is characterized by its size and by steel-blue sheen on the hindwing. — ***xanthus* L.** (63 b).

♂. Dark brown, very slightly tinged with reddish. Band of the forewing anteriorly only cut by the veins, but mostly from the bend onwards partially broken up into loosely connected spots. A more marked interruption occurs in particular at the middle median vein, whilst the posterior part is again connected proximally. At the proximal side there is a sharp and distinct angle in the upper median cellule, distally the band projects somewhat towards the distal margin in a rounded curve and in this spot-like part is placed a small whitish dot; the band terminates in a point in the hinder angle. Hindwing at the distal margin narrowly edged with reddish ochre-yellow from the apex to about the upper median vein. ♀. On the whole paler. Band of the forewing as a rule interrupted at the lower radial, so that it is split up into a short oblique band running distally to the cell and a row of 3 or 4 spots near the distal margin. The first of these spots, in the upper median interspace, is indistinct and anteriorly partly replaced by a whitish brown patch behind the eye-spot, which shows through from beneath; a less distinct light shade is observable in the following spot in the band. Hindwing as a rule lighter and more distinctly margined with yellowish. French and Dutch Guiana. — *soranus* Westw., known from Pará and in my collection from Obidas on the Lower Amazon in 2 pairs found by J. MICHAELIS in August and September, differs from *xanthus* in the broader red-brown band of the forewing and the lighter grey under surface of both wings. — *dohrni* Stich. (63 b). ♂ similar to the preceding, somewhat larger, apex of the forewing rounded, little produced, upper surface brown-violet, hindwing and subapical part of the forewing showing, when viewed obliquely, a beautiful violet gloss. Forewing with angled rust-yellow macular band, beginning at the costa, beyond the cell, running obliquely to the upper median, then near the distal margin in the direction of the inner angle, touching the latter. In the apex three obliquely placed white spots and between the radials, in continuation of the row of spots before the distal margin anteriorly, a black eye-spot showing through from beneath. Hindwing unicolorous, at the distal margin duller brown, without marginal band. Beneath likewise similar to *xanthus*, yellow-brown, striated with whitish. Forewing with unicolorous border, in which run 2 moderately undulate submarginal lines parallel with the distal margin. Between the radials a black, yellow-ringed apical eye-spot divided by a white streak, before this 3 small white apical spots as above. In the cell an irregular, black-margined, darker transverse band and similar contiguous spots in the distal part. Hindwing with two ocelli, one beyond the middle of the costa, extending across the subcostal, yellowish, black-edged, proximally with white curved streak; the other in the anal area between the lower and middle medians, likewise yellowish, bordered with black, proximally with a white curved streak, the whole ringed with yellow and reddish. Distally to the precostal cell, adjoining it, a semicircular dark stripe, an angled streak between this and the anterior ocellus. Before the unicolorous distal margin a row of crescents marked by weaker and stronger striation, tending to form two arcuate submarginal lines. Coca, Ecuador to the east of the Andes at about 260 m. (type). Pozuzo, Peru, in coll. FRUHSTORFER. The rare ♀ was found by FASSL also at Villa Vicencio, East Colombia, at about 400 m. above sea-level. It scarcely differs from the ♂, but has the wings somewhat more compact, the patches on the forewing more rounded and a narrow but distinct red-orange terminal border on the hindwing. The whole upper surface paler, yet appreciably blue-violet and in contrast to the ♂ glossy on the forewing also. Under surface paler, more extended grey-white.

O. orgetorix is a very distinct species, formerly only known from Central America, but recently discovered also in Ecuador in a distinct race, so that there are 2 geographical forms to describe: **orgetorix** Hew. (64 a ♂), chiefly found at the Volcan de Chiriqui. ♂. Band of the forewing broad and pure reddish ochre-yellow, at the costal margin whitish, starting narrowly there, behind the subcostal much widened, running obliquely to the upper median vein, there somewhat angled and more vertical posteriorly. In the lower median interspace there is sometimes further a small brown spot. Both margins of the band, but especially the distal, ill-defined, more or less broken or notched. Proximally the angulation is rather distinct, distally less noticeable. The band gradually narrows and in the hinder angle forms a sharp curved point placed close to the margin of the wing. The eye-spot near the apex shows through from beneath and is mostly more or less pupilled with white, the distal border of the wing only indistinctly and slightly lighter. Hindwing at the distal margin with a reddish ochre-yellow band 5—6 mm. in breadth, narrow and paler-coloured at its commencement at the costal margin and ill-defined proximally. In the hinder angle it becomes narrow and duller and is lost in the ground-colour. Fringes brown. ♀. Forewing tinged with violet excepting the duller brown basal area, and with whitish violet transverse band distally to the cell. This band starts at the costal margin not far from the end of the cell and is intersected by the brown veins; it is white in its anterior part, separated into spots, then running obliquely towards the upper median vein, touching the lower angle of the cell, where it is obtusely angled, runs somewhat in a proximal direction as far as the middle median, then obliquely towards the hinder angle and terminates broadly at the hindmargin. Its distal edge is rather sharply defined, its proximal on the contrary indefinite. Distal margin somewhat more distinctly edged with rust-brown than in the ♂. Hindwing with gold-yellow marginal band similar to that in the ♂, but much broader, up to 13 mm., likewise narrowed posteriorly, in the hinder angle vaguely dusted with rust-red. Panama, Nicaragua. — **magnalis** Stich. inhabits Ecuador. The ♂ larger than in the preceding subspecies, forewing more rounded, apex less produced. Band of the forewing narrowed and darkened, sometimes dusted throughout with smoke-brown. The

reduction in width is from the proximal side, so that the band appears to be placed nearer to the apex and its angulation is more pronounced. Its general course anteriorly is oblique from the costal margin towards the subapical eye-spot, which shows through from beneath, and from there in an obtuse angle towards the hinder angle. The distal border itself is distinctly lighter, so that between it and the band only a narrow stripe of the ground-colour remains, and this quite ceases posteriorly, the light shade of the band and that of the border here running into one another. Distal border of the hindwing narrower and duller, sometimes very little lighter than the ground-colour. In single cases the marginal band stands out somewhat more distinctly, its bordering being then strongly dentate. ♀ with broader, dull violet transverse band, less angled at the cell, anteriorly indistinct and distally strongly notched at the veins in the vaguely dusted bordering. The eye-spot in the apical part standing out very distinctly on the pale blackish ground-colour, distal margin more broadly bordered with lighter smoke-brown. This border is strongly dentate and rather distinctly defined, on the hindwing narrower and paler, light bone-coloured.

rivalis. **O. rivalis** Niep. is said to be very similar to *xanthus* L., agreeing in habitus with *xanthus dohrni* Stich. Wings somewhat narrower than in *dohrni*. Apex of the forewing almost pointed (?), distal margin more sinuate. Upper surface velvety chocolate-brown. Forewing with three apical patches, after these a black ocellus showing through from beneath, then posteriorly between the lower radial and the upper median a whitish yellow spot. The submarginal macular band not obtusely angled but gently curved. It consists of 7 spots of unequal size and of dark rust-yellow colour, mostly pointed proximally. The hair-pencil in the cell light brown, that at the submedian velvety black. Under surface as in *dohrni*, the yellow-brown colour more intensive, the white striation more pronounced, the black markings stronger. The posterior ocellus is said to be pear-shaped. Length of the forewing 54—55 mm. Maccas, Ecuador.

xanthicles. **O. xanthicles**, as its name already suggests, bears a certain similarity to *O. xanthus* L., but the hair-brush at the submedian of the forewing is less broadly attached and more bushy, pencil-like. **xanthicles** Godm. ♂. Dark brown, the band of the forewing runs from the costal margin at some distance distally to the end of the cell and parallel with the discocellulars obliquely to the upper median vein, is behind this bent round posteriorly in an obtuse angle and gradually tapers to a point towards the hinder angle. The proximal boundary is rather sharp and in places only a little notched, the obtuse angle somewhat rounded, the distal boundary projecting at the lower radial, the angulation sharper, otherwise running in a fairly uniform direction. Hindwing with several small, dull ochre-yellow apical spots or the rudiments of a marginal band at the apex. ♀. Ground-colour of the upper surface pale grey-brown, the apical area darker. Band of the forewing broader, pale ochreous. The widening occurs chiefly at the proximal side, so that the band is placed nearer to the cell and the obtuse angle is lost. The boundary-line forms here only a slight curve, whilst distally it shows exactly the same characters as in the ♂. Hindwing with more distinct, pale ochre-yellow marginal band, which, however,

cyparissa. just behind the apex is somewhat removed from the distal margin and vaguely diffused. Panama. — **cyparissa** Fruhst. (66 a). Ground-colour black-brown, forewing with the usual 3 white apical dots and with a dark ochre-yellow band traversing the wing from the costal margin (at a distance of about 7—9 mm.) distally to the cell and about the upper median approaching the distal margin, which it nowhere quite reaches. Towards the submedian the band is narrowed. On the hindwing it is continued as a moderately broad distal border, extending from the subcostal to the middle median and gradually narrowed posteriorly. Before the upper wall of the cell a long black hair-pencil (in *xanthus* this pencil is light yellow, in *berecynthia* black and small, in *amphirhoë* and *orgetorix* it is entirely absent), a still longer, thicker hair-pencil, distally strongly wavy, arising from a fold before the submedian, and the usual small grey scent-tuft in the bare scent-cavity proximally to the submedian. Under surface: basal half of the forewing dark brown, the submarginal area striated with white, the distal border anteriorly brown, posteriorly yellowish. From the black-pupilled apical ocellus onwards a narrow, sharply pronounced violet-white submarginal band traverses the wing. Hindwing with a broad, oblique brown median band, crossing the lower part of the cell. Round the large brown-ringed anal ocellus a broad, somewhat coffee-brown patch; otherwise with dense, fine white striation throughout with the exception of the greenish brown distal border. Two black undulate antemarginal lines extend on the hindwing from subcostal to submedian, on the forewing they become indistinct before the middle median. ♀ uniformly black-brown, the white apical patches somewhat larger than in the ♂. Band of the forewing nearly twice as broad, only moderately narrowed costally and anally, between the lower radial and the upper median enclosing a white dot in the distal part. Marginal band of the forewing compact, ochre-yellow, proximally with reddish gloss, sharply defined as far as the inner marginal vein. Under surface more copiously striated with white than in the ♂. Terminal border with brighter yellow-brown edging. Muzo, Colombia, 4—800 m., ♀

belisar. discovered by FASSL. — **belisar** Stich. Larger than the typical subspecies, of a darker ground-colour. Band of the forewing somewhat broader, bright reddish brown; proximal boundary-line without distinct angulation, crenate, distal boundary as in the typical subspecies. Hindwing with a bright reddish ochre-yellow marginal band 5—7 mm. in breadth at the distal margin, starting in a point at the apex, soon developing into the cell band and remaining distinct nearly to the hinder angle, where it is lost in the ground-colour in a vague dusting; its proximal boundary is somewhat curved. Otherwise like the typical subspecies. Length of the forewing 54 mm. Bolivia (province of Yungas, La Paz).

O. singularis Weym. ♂ above dark brown, in the end of the cell and behind it somewhat reddish. *singularis*. Apical area black-brown. In the distal part of the cell an irregular, deep ochre-yellow spot. Beyond the cell runs an ochre-yellow transverse band, curved somewhat basewards in the anterior part; it consists of 6 spots, of which the first three are more closely, the posterior ones loosely connected; at the upper median vein a rounded wedge of the ground-colour projects from the cell into the band, making a deep excavation in it. Near the apex is placed a comparatively large, rounded, light ochre-yellow spot. Hindwing nearly oval, from the base onwards brown; beyond the cell this colour gradually changes into rust-red and finally into an undecided deep ochre-yellow marginal band; before the subcostal, distally to and near the precostal cell, is placed an anteriorly directed ochre-yellow hair-tuft, in the posterior part of the cell and between this and the submedian strong brown hair not arranged in pencils or tufts, and on a bare friction-patch at the hindmargin, about in the middle of the submedian, a very small hair-pencil. Under surface of the forewing brown, variously clouded and shaded with lighter and darker. In and at the end of the cell confused black lines, which enclose and cover two band-like brown areas; between these some whitish dusting. In the lower radial cellule there is a black eye-shaped spot. Distal margin grey-brown; near it run two black lines, both lost near the hinder angle in the ground-colour, which is there grey-yellow. The apex is somewhat ochre-yellow, the hindmarginal area smoke-brown. On the submedian, near the base of the wing and covered by the anterior part of the hindwing, is placed a small, oblong ochreous scent-scale spot. Hindwing light brown, the proximal costal area before the costal somewhat darker, with transverse white striation, the part of the wing behind this area as far as the median covered with irregular dark figures; distally hereto there is a large, roundish, eye-like spot of various shades of brown, ringed with black-brown. In the posterior part of the wing there is a second black eye-spot, placed in a light brown ring, its inner disc dusted with yellowish and bearing a white streak; the whole is ringed with black-brown and stands in a brown-violet area. The rest of the wing striated and marbled with black-brown, the distal area more uniform brown, while the central part has a slight violet sheen; the striation is sharpest in the hindmarginal area. Length of the forewing 44 mm. Guatemala, only 1 ♂ known.

O. amphirhoë represents the *Catoblepia* group in central and southern Brazil. The species may be easily known by its characteristic light grey marbled under surface, on which the apical eye-spots are displaced far towards the distal margin. Two well differentiated local forms: **amphirhoë** Hbn., name-type probably *amphirhoë*, from Rio de Janeiro, where according to BÖNNINGHAUSEN (who erroneously called it *xanthus*) the larva, which is of a sea-green colour, lives on prickly palms. Both sexes essentially larger than the figured *placita*, the ochreous band correspondingly broader. Not very rare in Espirito Santo. — **placita** Stich. (64 a) is always smaller, *placita*, the band of the forewing always continuous, not broken up in the anterior intramedian area, as in *amphirhoë*. Under surface much darker. Forewing only with grey patches in the cell. Hindwing with more pronounced black clusters of scales, which are condensed and developed into a kind of submarginal band. Apparently common at Blumenau in Santa Catharina (8 ♂♂, 2 ♀♀ in coll. FRUHSTORFER); very rare in Rio Grande do Sul, whence I only have 2 ♂♂ from Candelaria. According to STICHEL an intermediate form seems to occur in São Paulo, details of which are not yet known. There is still much to be desired as regards the exploration of Brazil, which will provide one of the most remunerative tasks for the future.

b. Section Polyophthalmi.

Under surface of the hindwing with a curved row of 5 or 6 ocelli. ♂ above always with a hair-pencil in the posterior part of the cell, a smaller one behind the submedian and a brush-like tuft between this and the lower median.

O. berecynthia somewhat resembles *O. xanthus* L., except that the wings are more rounded and the scent-hairs at the submedian are drawn out into a pencil instead of attached as a broad brush. Several geographical races, some of them very sharply differentiated. **berecynthia** Cr. Band of the forewing varying in *berecynthia*, breadth, in quite typical specimens only narrow. It runs obliquely, without touching the cell, from the costal margin to the upper median vein, is then angularly curved posteriorly, gradually approaches the distal margin, is narrowed and terminates in a sharp point not far from the anal angle. Its proximal boundary is fairly smooth, only at the middle median vein somewhat notched, its distal margin less sharply defined, more or less incised at the veins. Hindwing with complete but narrow, or partially indistinct, rust-red band at or near the distal margin, in the former case as a rule only posteriorly touching the margin, anteriorly somewhat removed from it. On the underside of the forewing the proximal of the submarginal lines only weakly curved, the distal one placed rather near the margin. ♀ paler, band of the forewing broader, its proximal boundary touching the discocellulars, at the posterior angle of the cell, between the middle and upper median veins, projecting basewards in a tooth, the angulation less sharp, but quite appreciable at the distal boundary. Hindwing at the distal margin with complete rust-red band, which in the anterior part is somewhat removed from the margin. Under surface less bright, the lines near the distal margin of the forewing more strongly curved. Two known aberrations in the form of the band: **latitaenia** Fruhst. (64 a). Band of the forewing widened and strongly *latitaenia*, angled, the yellowish distal margin of the hindwing dull. **velata** Stich. Band of the forewing narrowed and *velata*, darkened, partially, occasionally even entirely, blurred and indistinct. In the ♀ the difference is less striking,

but the band is paler in colour, occasionally likewise washed-out and somewhat darkened, always narrower than in the type-form; it remains as a rule somewhat removed from the end of the cell, more rarely slightly touching it at the origin of the lower radial. Hindwing in the ♂ unicolorous or only with indistinct or clouded remains of the marginal band; in the ♀ the posterior part of this band is present, but dull, anteriorly it is obsolete or transformed into small dull spots. Guiana and Lower Amazon. — *midas* Stich. Type from Coca in East Ecuador. ♂: ground-colour dark black-brown. Band of the forewing less sharply bent than in the typical subspecies, forming at the proximal boundary only a slight curve, at the distal an obtuse angle in the upper median cellule. Proximally it is but little incised at the veins, at the middle median occasionally somewhat more strongly, distally it is more broken and less sharply defined. In the hindwing there is a narrow rust-yellow distal band, which starts posteriorly in a point, in the hinder angle immediately adjoins the distal margin, and is there broadest, about 4—5 mm., is then removed to about the same distance from the margin, narrowed and broken up into spots. — *luxuriosa* Stich. ♂: differing from the preceding in having the band of the hindwing only present as a broad rust-yellow spot in the anal angle, about from the submedian to the upper median. The distal margin otherwise unicolorous. Band of the forewing broad, the distal boundary somewhat dentate and angled, the proximal likewise incised at the veins, filling the upper part of the cell. Ocelli on the underside of the hindwing large and brightly marked. Each surrounded by a broad rust-yellow patch, the patches connected so as to form a sinuous undulate band, in which the ocelli are placed. Length of the forewing 49—50 mm. ♀ larger than the ♂, ground-colour lighter. Band of the forewing extending considerably into the distal part of the cell, so much so indeed, that the latter is filled up with rust-yellow from the upper angle to the origin of the middle median. Length of the forewing 54 mm. Colombia (Muzo?). — *vicenciona* subsp. nov. somewhat resembles *unditaenia* above in the band of the hindwing, on the other hand that of the forewing, as in *luxuriosa* Stich., touches the apex of the cell, but is distally even somewhat more broken and anally narrowed. Before the cell-wall, just at the origin of the lower radial, stands a circular spot, which is not broadly diffuse as in *luxuriosa*. Subterminal band of the hindwing deeper reddish yellow than in *unditaenia*, anteriorly not broken up into separate spots and anally extending to the distal margin, thus somewhat widened. Under surface: cells red-brown, but the apical part and the whole submarginal area of the forewing grey-violet, hindwing with four green-pupilled posterior eye-spots and two anterior ones filled up with reddish. East Colombia, Villavicencio, 400 m. (FASSL leg.). — *adjecta* Stich. ♂ above deep black-brown. The band of the forewing proximally touches the discocellulars and is gently bent, not angled as in the typical subspecies, also somewhat broader on an average. Distal marginal band of the hindwing towards the hinder angle considerably widened, anteriorly narrower, at the apex tapering to a point and in the anterior half somewhat removed from the margin. The bands of both wings bright reddish ochreous. Under surface, as in the following subspecies, brightly coloured, the distal eye-spots occasionally developed into a complete chain across the entire breadth of the wing. Bolivia, Amazons (in transitions). — *berecynthina* Hopff. (= *vercingetorix* Stgr.). ♂: band of the forewing proximally widened in such a way that the angle is completely filled in and the boundary-line runs in a curve. The proximal boundary occasionally crosses the distal part of the cell, the discocellular, however, remaining brown. In this case its margin is incised at the median and anteriorly in the cell vaguely dusted. At the distal boundary the angle in the upper median cellule is, however, more distinct. The posterior part and the point at the extremity are much broader than in the typical subspecies. Hindwing at the distal margin with an entire-margined band, which starts in a point at the hindmargin, quite near the hinder angle, soon widens to a breadth of 8—9 mm., anteriorly is gradually narrowed again and somewhat removed from the margin, and terminates almost in a point in the apical area. In transitional specimens the band is narrower in the posterior part, the narrowing less gradual and the anterior part more or less broken up into spots. ♀: the band of the forewing crosses the distal part of the cell, at least its posterior angle; band of the hindwing similar to that of the ♂, but still broader, up to 12 mm. The bands of both wings paler in colour than in the ♂, the brown ground-colour also less deep, the eye-spot of the under surface between the radials of the forewing showing through strongly above as a filled-up black circle. Peru, Bolivia. — *unditaenia* Fruhst. (64a) was already known to HÜBNER and figured by him as *berecynthia*. But HÜBNER's and our figures differ considerably from CRAMER's name-type: 1) in having the band of the forewing not elbowed or angled, but forming a neat curve; 2) in the broader and more intensively red-yellow bands of both wings; 3) in the brighter red-brown under surface. These three differences at once characterize the new local form which has not hitherto been noticed and in which the bands are almost as much widened as in the typical *berecynthia* Cr. ♀♀, but brighter coloured and more sharply defined. I have seen no examples in which the black border occupies the entire distal margin, as in HÜBNER's figure. In my Rio ♂♂ this border only reaches to the upper median; this and some other variations are naturally unimportant and mostly individual. In respect of the tertiary sexual characters, *unditaenia* differs from the type in four modifications: 1) the much longer and denser hair-tuft at the inner margin of the forewing; 2) the scent-pencil at the upper cell-wall of the hindwing much stronger and completely covered by this hair-tuft; 3) the entirely black hair-pencil (in *berecynthia* basally yellow); 4) the longer hair-tuft in the shiny scent-cavity of the submedian. Coll. FRUHSTORFER, type 1 ♂ from Rio de Janeiro, according to STICHEL 1 example from São Paulo in coll. STAUDINGER.

O. generosa Stich. ♂. Nearest to *O. berecynthia* Cr. Larger, stumpier, forewing with rounder apex. *generosa.* Ground-colour black-brown. Forewing with three small white apical spots and a broad, elongate, oblique gold-yellow discal band, of which the distal boundary runs near the cell, outside it, and the proximal boundary crosses it, so that fully one-third of the cell is filled up with gold-yellow. The margins of the band, especially the distal, not appreciably dentate. Beneath the ground-colour beyond the cell is yellowish, strigulated and clouded with black-brown, gradually becoming duller, particularly in the anterior part. Near the apex there is some whitish striation and the three small white spots of the upperside. Between the radials is placed a round, black, yellow-ringed and blackish-bordered eye-spot, containing a white streak. Distal marginal area separated from the striated part of the wing by a concave ochre-yellow stripe, which is particularly brilliant posteriorly. Hindwing above unicolorous brown with the exception of the hinder angle, which is golden yellow, and from which the beginning of a band bordered with duller yellow can be traced near the margin almost to the upper median vein. Sexual characters as in the preceding species, but the tuft before the median and the small pencil on the bare friction-patch at the submedian are wanting. Under surface yellow-brown, with two blackish lines in a narrow distal marginal area. The rest of the wings striated and clouded with brown; adjoining the precostal cell a yellow-red, dark-margined spot, two similar, less distinct spots in the cell. Distally to these an undulated row of 6 more or less distinctly ocellated, round spots, the posterior 4 or 5 connected into a sort of chain by a light bordering. The first spot, placed behind the middle of the costal margin, red-yellow bordered with black, enclosing a white curved streak, the following two with indistinct pupils, the rest with large black pupils, which are almost entirely dusted over with greenish yellow and anteriorly also more or less distinctly edged by a white curved streak. Between this chain of spots and the distal marginal lines whitish striation, which stands out from the reddish ochre-yellow ground-colour in loosely connected lunules or pointed marks. Eastern Ecuador, Peru (Pebas).

Group *Selenophanes* Stgr.

Upper and middle discocellulars sharply right-angled. Costal and subcostal narrowly but distinctly separated. The latter 5-branched. Two branches before the end of the cell, the first at some distance proximally, the second just before the cell, the third branch arising midway between cell and apex, all three into the costal margin, the fourth arising shortly before the apex, running into it, followed by and forked with the fifth. Cell long, only moderately broad, distally rectangular at both sides. Anterior discocellular very short, middle arising at an acute angle from this, shortly curved and then continued without a break by the somewhat longer posterior discocellular. Median in the ♂ inflated near to the base. One species (*O. cassiope* Cr.) beneath before the submedian with a raised, mealy scent-spot, to which corresponds a mealy friction-patch between the costal and subcostal on the upperside of the hindwing. Hindwing with the apex rounded and the anal angle mostly rather pointed, only in one species (*O. josephus* Godm. & Salv.) rounded; ♂ without manifest hair-pencils or brushes, but between submedian and median with long hairs, in two species (*O. supremus* Stich. and *josephus* Godm. & Salv.) above the subcostal, close to the precostal cell, an anteriorly directed hair-tuft, covered by the hindmargin of the forewing, one species (*O. josephus*) with an almost triangular pilose black scent-spot between the posterior and middle medians. Precostal cell very narrow, precostal vein extending considerably beyond it. Costa proximally strongly lobed. Cell narrow and long, more than half the length of the wing. Abdomen without lateral friction-glands or protuberances.

a) Forewing of the ♂ beneath with pilose scent-spot before the submedian. Hindwing with mealy friction-patch before the subcostal or erect hair-tuft close to the precostal cell.

O. cassiope Cr. Dark brown, at the costal margin near the apex almost black. Oblique band of the fore- *cassiope.* wing anteriorly pale, then light reddish ochreous; it runs from the costal margin obliquely to the hinder angle, where it forms on the submedian a blunt point bent towards the hindmargin. Breadth of the band about 8—10 mm. Hindwing unicolorous, sometimes with a somewhat obscure yellowish brown band near the distal margin or immediately at it. Mealy spot in the costal area grey-black. ♀: larger; mostly duller, with the band of the forewing somewhat paler. The latter, however, considerably broader, up to 12 mm., posteriorly more obtuse, distally more dusted and broken, but, as in the ♂, running for its whole length outside the cell, although with its proximal boundary touching the discocellulars. Distal margin below the apex narrowly dusted with more or less bright yellowish, this dusting sometimes developed into a sharply defined band as far as the middle median and then gradually shading into the brown ground-colour. Hindwing usually unicolorous with dull brownish yellow distal-marginal dusting behind the apex. This dusting as in the forewing occasionally consolidated into a band, but before the hinder angle gradually becoming duller and more indefinite; sometimes there is also a more or less distinct undulate band near the distal margin, about from the subcostal to the upper or middle median vein (transitions to *amplior* and *cassiopeia*). Guiana, northern Brazil (Lower Amazon). — **cassiopeia** Stgr., from the Upper Amazon and Peru. ♂: band of the forewing as a rule not *cassiopeia.* so broad as in the preceding subspecies, proximally likewise filling up about one third of the cell, distally more regularly oblique. Its proximal bordering more strongly broken, especially deeply incised at the median and in the lower median cellule, the distal boundary also sometimes more broken up. ♀: band of the forewing of uniform breadth, a very large quadrate spot before the apex of the cell. Hindwing with distinct yellowish grey marginal band, deeply incised proximally, and a narrow reddish yellow submarginal band, which disappears at the middle median. Under surface darker than on STAUDINGER's figure of the ♂ in Exot. Tagf. pl. 71. Hind-

amplior. wing only towards the costa slightly lighter. Villavicencio, East Colombia, 400 m. — *amplior* *Stich*. An intermediate form between *cassiope* and *cassiopeia*. Smaller than the latter. Band of the forewing broader, bright orange-yellow, margins less dentate. Submarginal band of the hindwing narrower than in the preceding, but distinct, undulate (crescentic), present from the costa to the lower median, then obsolete, shading into the ground-colour. Length of the forewing 54 mm. 1 ♂, from Colombia. This form also occurs on the Lower

theognis. Amazon as an aberration together with the type-form. 1 ♂ in coll. FRUHSTORFER from Obidos. — *theognis* *Fruhst.*, from Matto Grosso, is a further intermediate form connecting *cassiope*, *cassiopeia* and *placencia* and differing from all three in having the band on the forewing brighter red-yellow but much narrower. The hindwing has a grey-brown distal border composed of crescentic patches filled in with deep black, and a distinct longitudinal line, anteriorly somewhat ochreous, anally red-brown. Under surface lightened as in *cassiopeia*.

placencia. — *placencia* *subsp. nov.* ♂: intermediate between *theognis* and *cassiopeia* *Stgr.*, but approximating more to the neighbouring race from Brazil. Band of the forewing more regular, broader and of lighter yellowish ground-colour. Hindwing with the markings more washed-out, the black submarginal band in particular more broken up, the yellowish postdiscal band anally lighter. Under surface with more extended dark shading in the distal area, with more prominent black lines. Coroico, Bolivia, 1200 m.

andromeda. *O. andromeda* *Stich*. Bolivia. A handsome species. Oblique band of the forewing broader than in *cassiope*, fiery rust-yellow, at both sides darker and with dashes projecting into the ground-colour. Distal margin of the hindwing broad, over $\frac{1}{2}$ of the latter fiery rust-yellow, proximally darker, gradually shading into the ground-colour. Next to the distal border a submarginal black undulate line. Ground-colour of the under surface reddish brown, less whitish than the Amazon form and *placencia* *Fruhst.*

supremus. *O. supremus* differs from *cassiope* in the straighter course of the band of the forewing. Two very rare subspecies: *supremus* *Stich*. Apex of the forewing moderately produced, distal margin correspondingly shallowly excised. The zigzag band of the forewing in the middle about 8 mm. in breadth, anteriorly smooth-margined, posteriorly rather sharply dentate; it forms in its general course two curved sections, an anterior one from the costal margin to the middle median vein and a somewhat shallower one from there to the hindmargin. On the middle median it projects in a long pointed tooth proximally towards the cell. Band of the hindwing present near the distal margin and in the middle part, from the upper radial to the upper median, as two connected, pointed curved spots. Before and behind this only some dull brownish dusting is visible, indicating the continuation of the band. The middle part of the band is likewise ill-defined and slightly darkened.

ditatus. Ecuador. — *ditatus* *Thieme* is somewhat larger, apex of the forewing a trifle more produced, distal margin somewhat more deeply concave. Band of the forewing a little narrower, on the other hand the bright rust-yellow band near the distal margin of the hindwing broader, more sharply expressed and completely formed almost to the hindmargin. It is likewise composed of pointed curved spots, its margin projecting distally in pointed curves in the interneural spaces, and being proximally hollowed out at the same places and on the veins produced into points. Distal margin of the hindwing tinged with yellowish brown, lighter and more decided than in the typical subspecies. Southern Peru and Central Peru (Huancabamba, 1500 m.).

josephus. *O. josephus* bears a nearly triangular black scent-spot between the lower and middle medians on the forewing above. The ocelli of the under surface, in contrast to those of *O. cassiope*, are oval or rounded instead of reniform or falcate. Only a few examples are known, which divide into two local forms: — *josephus* *Godm.* and *Salv.* Apex of the forewing in the ♂ pointed, almost falcate. Transverse band ochre-yellow, posteriorly more reddish, its inner margin jagged, especially in the anal part of the wing. Before the apex 3 small white spots. Beneath the lines before the distal margin are less undulate and diverge but little in the middle. Guatemala.

excultus. — *excultus* *Stich.* (66 a). Apex of the forewing somewhat more obtuse. Band broader, deeper reddish ochre-yellow, its proximal margin less incised and broken; it is of a whitish yellow tone at its commencement on the costal margin, and 7—8 mm. in breadth; runs obliquely to the anterior median vein, touching the discocellulars; is distally dentate before this vein, proximally somewhat retracted behind the cell, and from here directed somewhat more vertically towards the hindmargin. Its inner margin is somewhat sharply broken at the middle median vein, in the interneural spaces slightly incised, its outer margin notched at the two anterior median veins, afterwards entire. The band terminates in a basally directed point in the anal angle. Hindwing unicolorous, or with a narrow, curved, obscure rust-red band before the distal margin. The lines near the distal margin on the underside of the forewing in the middle somewhat more divergent and more strongly dentate, underside of the hindwing deeper brown. Colombia.

lutescentefasciatus. *O. lutescentefasciatus* *Kirby* is a doubtful species of the subgenus *Opsiphanes*, and is only mentioned here because KIRBY has given it in his "Catalogue". In shape and size similar to *O. cassina cassina* ♀; upper surface brown, above and beneath a broad yellowish median band running parallel with the distal margin. Under surface reddish, the band deep yellow.

6. Genus: *Eryphanis* *Bdv.*

The species united here were formerly referred to *Caligo*, until BOISDUVAL separated them in 1874 as a distinct genus, although the differences in neuration are of little importance, the divergence consisting rather in the different form of the ♂ sexual characters. *Eryphanis* differs superficially from *Caligo* in the weaker build of the body and mostly in the fiery colouring of its species. In the neuration of the forewing the middle

discocellular and the lower are not so long as in *Caligo*, not so transversely placed, but obliquely joining the median at its 3rd branch. This same is the case with the cell of the hindwing, but the precostal cell is quite as small as in *Caligo*. The ♂♂ possess at the inner margin of the hindwing a strikingly large elongate or rounded, yellowish pilose spot, consisting of long, spatulate scent-scales. In addition they have, like *Caligo*, a shiny area, of lackered appearance, at the submedian, corresponding with a gland on the abdomen; the hair-pencil is wanting. The clasping-organs show more analogy with *Opsiphanes* than with *Caligo*, to which the genus is otherwise apparently nearer. Tegumen as in *Opsiphanes* and the *Satyridae* with a hook-shaped uncus which bears two lateral, ventrally smooth points. The valves long, slender, dorsally sharply dentate. The range of this genus extends over northern South America and through Central America to Mexico. In the south, like the genus *Opsiphanes*, it does not extend beyond Rio Grande do Sul and Bolivia. — Egg the same size as those of the Morphids, spherical, somewhat flattened above and beneath and on these flattened parts dark brown, otherwise whitish grey. Round the greatest circumference runs a broad, deep dark brown stripe, which, however, at one side is not closed but remains open for about $1\frac{1}{2}$ mm. Larva on bamboo. It keeps the anal fork compressed, so that it looks not unlike a Sphingid horn. Pupa elongate and as pointed at the head as at the anal end. According to Dr. HAHNEL the butterflies present a magnificent show of colour when in the shade of the woods they suddenly let their wonderful deep dark blue flash out. According to my experience in Santa Catharina the *Eryphanis* are fond of feeding at the sap flowing out of trees in the undergrowth, on the stems of which they sit with the wings folded, and it is also occasionally possible to attract them with overripe bananas. They are, however, nowhere found in large numbers. — Only 6 species are yet known. They are divided into two unequal groups according to whether a brush of hairs is present on the friction-area of the hindwing.

a) ♂ without hair-pencil on the bare inner-marginal area of the hindwing.

E. polyxena, distributed in collections under the name *automedon* Cr., inhabits the whole of South America from Venezuela to Paraguay, also Central America and Colombia to Ecuador and Peru, and splits up into five known branch-races: **lycomedon** Fldr. Forewing in the ♂ blue-violet in the discal part, distal margin *lycomedon*. dirty ochre-yellow, band washed-out; hindwing dark brown with narrow yellow-brown distal margin and dull lilacine gloss; ♀ dull brown, the end of the cell darker, in the dark brown distal area a rather sharp, ochreous undulate band, anteriorly forked, but the outer branch washed-out. Disc of the forewing with a dull, grey-blue gloss; in the cell sometimes 2 diffuse spots. Disc of the hindwing with blue-green reflection. Central America and Colombia. — **polyxena** Meerb. (64 b ♂, c ♀ as *automedon*). Above black-brown; ♂ nearly black, *polyxena*. discal part of both wings with beautiful blue reflections; forewing before the distal margin often with narrow yellowish band, forked towards the costa. ♀ duller, costal and apical borders yellow-brown, basal half grey-brown, distally with slight blue-green reflection. Venezuela, Trinidad, Guiana, North and Central Brazil, about as far south as to Rio de Janeiro. — **wardi** Bdv., originally coming from Matto Grosso, but at first described *wardi*. by its author himself with the erroneous locality "Guatemala", was a lost form, of which I first received authentic examples last year, from the neighbourhood of Cuyaba, Matto Grosso. *wardi* is distinguishable above from *polyxena* by a slight violet shade, somewhat agreeing with that of *lycomedon*, and the more marked, pale yellowish, but still obsolescent submarginal band connects it with *novicia* from Ecuador and *lycomedon* from Colombia. The ♀ may readily be distinguished from the Brazilian *polyxena amphimedon* by an extended, nearly light yellow subapical (transcellular) area and two isolated yellow patches before the apex of the cell of the forewing. — **amphimedon** Fldr. has very extended indigo-blue gloss on the upper surface, encroaching on the obscure yellowish band before the distal margin and on the hindwing only leaving a narrow margin. Distal *amphimedon*. margin of the hindwing less strongly angled at the lower median vein; ♀ with the blue colour more extended and more brilliant. Hindwing purer blue-grey in the basal part, the latter more sharply defined. According to VON BÖNNINGHAUSEN very rare in shady places at Rio. Larva described in the generic diagnosis. From Blumenau, Santa Catharina, in my collection; according to STICHEL also in Paraguay. — **novicia** Stich. Some- *novicia*. what smaller than *lycomedon*. Above darker, predominantly brown, with only a slight violet tinge in the central area of the forewing. The band near the distal margin of the latter purer. Hindwing distinctly angled, narrowly but rather sharply margined with ochre-yellow. La China, province of Los Rios (Ecuador). — **tristis** Stgr. The ♂ differing from the preceding subspecies in having much less blue on the hindwing. This *tristis*. dusting is here only present near the apex as a small spot, which at an oblique angle of light occupies a larger space. Southern Peru. — **cheiremon** subsp. nov. closely approaches *wardi* Bdv. from Matto Grosso, as is so com- *cheiremon*. monly the case in Bolivian subspecies, but is larger and bears a much longer yellow mealy spot in the anal fold of the hindwing. The blue of the upper surface is brighter, on the hindwing more sharply defined. The under surface more resembles that of *lycomedon* Fldr. from Colombia, but the subbasal part of the forewing and the basal area of the hindwing are silver-white instead of yellowish resp. grey-brown. Ground-colour in general also lighter, rather to be called grey than brown. Coroico, Bolivia, 1200 m. — **spintharus** Fruhst. A conspicuous *spintharus*.

local form from eastern Colombia, which there replaces *lycomedon* Fldr. and is much nearer to the Bolivian *cheiremon* and *wardi* Bdv. from Matto Grosso. ♂ with the submarginal band of the forewing nearly twice as broad as in *lycomedon* and grey instead of yellowish, the refleteion on the upper surface brilliant blue, not violet; ♀ differing from that of *polyxena* Meerb. in having a broader, paler yellow-grey longitudinal band on the forewing, distally enclosing two large black spots (ocelli). Apex of the cell and the whole circumcellular region pale yellow-grey. Basal part of the cell black instead of dark blue as in *automedon*. Hindwing with only a restricted glossy blue discal area. Cell grey-black, the distal border extending nearly to the cell, deep black. Under surface lighter than in *automedon*. Apex of the cell and median part of the forewing, basal and median area of the hindwing nearly whitish grey, with slight purple tinge. Upper Rio Negro. East Colombia, 800 m., discovered by FASSL.

E. reevesi divides into three branch-races in central and southern Brazil. In habitus it approaches *E. polyxena amphimedon* Fldr., together with which it occurs. The ♂, however, is easy to distinguish from *amphimedon* by its smaller size and dark blue-violet ground-colour and the ♀ by its brighter yellow but narrower bands. *reevesi* is regarded as the commonest of the known species; it is not difficult to bait it with fruits spread out or hung up and it is found in Sta. Catharina, both in the elevated localities and in the hot valleys at the "Waldschänken", where it often drinks at one place for hours. But the scales are very loosely attached and it is difficult to obtain perfect specimens. — *hemichroa* Btlr., described from Minas Geraes, probably differs somewhat from exemplars from Rio de Janeiro and Espiritu Santo, and may be taken to include specimens from Bahia, which differ from more southern *reevesi* in their small size and also in the somewhat paler violet of the upper surface and the predominantly pale grey-brown under surface, which in Bahia ♂♂ appears washed-out as in the more southern ♀♀ of the collective species. — *reevesi* Westw. extends with little variation from Espiritu Santo to Santa Catharina, where I found it from January to March in dark forests. Forewing of the ♂ dark brown, distal margin grey-yellow; distal part tinged with deep violet; this colour is anteriorly broad, extends into the posterior, projecting angle of the cell, and is narrowed towards the hindmargin; the apex remains free. Hindwing similar, but with the violet shade darker and still more ill-defined. In an oblique light the blue shows here distally and behind the cell as a vaguely defined median area, brighter on the veins than in the interspaces. Scent-spot in the anal area spongy, surrounded by a narrow, light glossy ring, placed in a distinct hollow in the membrane of the wing, visible on the under surface as a raised swelling. Length of the forewing, ♂ 53, ♀ 55 mm. — Larva (according to G. W. MÜLLER) on *Olyra latifolia* L. and *Bambusa*; it sits close and broadly appressed on the underside of the leaves. Body when young yellowish with red dorsal and lateral stripes, slender, posteriorly narrowed, with long forked tail, which in the resting posture is horizontally pressed together or separated and erected. Afterwards green-red with dark dorsal line, red, white and brown longitudinal stripes; when full-grown the dorsal area pure green, posteriorly and anteriorly narrowed, terminating in a point on the 11th segment, finely edged with brown; lateral stripes brown and white, at the posterior margin of the middle segments black warts (false spines) of considerable size. Head large, broad, elongate, anteriorly steeply sloped, approximately quadrate, with 3 pairs of short horns; at first whitish with brown stripes, afterwards dark green in the middle with white, brown-edged stripes, which viewed from above, run in the same direction as the stripes of the body. — Pupa elongate, similar to the rolled-up leaf of a Monocotyledon, with very long horns placed close together, angles indistinct, ground-colour dirty brown-yellow.

E. zolvizora is a very rare species, which is distributed from Colombia to Bolivia and of which two branch-
zolvizora. es have been described. — *zolvizora* Hew., originally from Bolivia, perhaps distributed northwards as far as Peru. Upper surface dark red-brown with a band on the forewing composed of four or five crescentic ochre-yellow spots and yellowish brown terminal border on the hindwing. Under surface brown with a broad yellowish white subbasal and an angled, similarly coloured but much narrower median band. Otherwise very similar to *reevesi*, which it replaces in Bolivia and the Andean region. Known to me from Corsico, Bolivia, 1200 m. —
opimus. *opimus* Stgr. is the northern branch. In it the band of the forewing is more continuous, somewhat narrower, the longitudinal stripes on the underside somewhat extended, more yellowish, somewhat narrower. Type from Manizales, in the Cauca Valley, West Colombia, before me from the Rio Aquaca Valley, West Cordillera, Colombia, from 2000 m. In Ecuador and Peru occurs an allied race, which has not yet been sufficiently noticed, although STAUDINGER has already pointed out some slight differences. The egg is similar to that of *C. oberthueri* Deyr. in size and appearance, but with protuberances at both sides. The colour is bone-white, but in consequence of a fluid which is secreted by the ovipositor it looks as if irregularly plastered with rose-red. The rare ♀ mostly attains the size of a small *Caligo*.

E. seleucida Hew., another rare species, is above similar to *Caligo illioneus* Cr. Under surface remarkable for the strikingly large ocelli. ♂: above rust-brown, anteriorly in the median area somewhat lighter, distal area broadly dark brown, the margin itself narrowly dirty ochre-yellow. Near the distal margin with a narrow, undulate, ochre-yellow, slightly reddish transverse band, from which arises anteriorly, but indefinitely connected, a short, strongly curved and angled, somewhat duller coloured accessory band, which, however, like the main band, does not quite reach the costal margin. In the fork of the bands 2 black spots and at the end of the principal branch

of the band 2 small white dots. Beneath the median area forms a broad band, brown, distally tinged with lighter and darker ochreous, bordered on each side by a whitish stripe and distally in addition bounded by a twice broken black-brown line. Succeeding this the distal area is in its anterior, triangular part brown striated with white, posteriorly and distally with two black, yellow-ringed eye-spots, placed one behind the other, before these another black spot and two blind eye-spots near the apex. The area distally to the cell copiously dark-striated, bounded by a dark undulate line edged with ochre-yellow or whitish. Distal area rust-brown, likewise with dark, whitish-bordered line near the wing-margin. Hindwing with pale brown hindmarginal area, a bare friction-patch with pencil-like hairing between submedian and hindmarginal vein and a large mealy scent-scale spot in the region of the hinder angle. Ground-colour otherwise dark brown, in the middle of the wing tinged with reddish, distal margin narrowly bordered with rust-brown. Under surface in the basal and distal areas brown, profusely striated with black or black-brown. Median area broadly band-like, dark brown with white bordering. The area behind the eye-spots more or less striated with whitish. In the anterior part of the median area is also placed a large dark brown eye-spot with yellowish ring and white pupil. In the distal marginal area there is an undulate line bordered with light brown. ♀ unknown. Bolivia.

b) with brush-like hair-tuft close to the submedian of the hindwing.

E. aesacus comes from Central America, extending from Mexico to Colombia and dividing into two local forms: **aesacus** H.-Schäff. (64 b) is the smaller subspecies. ♂: Forewing near the distal margin with faint ochre-yellow transverse band, which is distinctly forked anteriorly as in the preceding species and almost to the same extent as in the ♀ of the present subspecies. The median area of indigo-blue tone, anteriorly only distinct as far as the upper median and the end of the cell, distally as far as the transverse band, which is itself faintly tinged with blue. Hindwing behind the apex near the distal margin with the blue tinge only in patches, in the middle of the wing becoming more or less of a band posteriorly. The distal margin is very nearly round, only at the middle median vein with an obtuse, scarcely appreciable angle. ♀ paler, the pale blue tinge on the forewing of a light violet tone, vaguely defined, leaving the end of the cell free, but rather distinctly developed into a broad band from the costal margin obliquely to the hindmargin. Hindwing at the base without blue dusting; indistinct traces of this first appear near the middle of the cell, whence it gradually increases in sharpness and forms in the middle of the wing a spot extending to just beyond the end of the cell and there somewhat more sharply defined. Mexico (from whence the type came), Guatemala and Nicaragua. Everywhere rare. From Honduras in coll. FRUHSTORFER. — **buboculus** Btlr., described from Costa Rica, extends southwards to Colombia. Larger than *aesacus*, darker coloured and beneath more sharply marked. According to FASSL is one of the highest flying Brassolids in the Colombian Andes. — **juruana** subsp. *juruana*. nov. has rounder wings, is above more blue instead of violet and the yellow submarginal band of the forewing is narrower. From the Rio Juruá, a southern tributary of the Amazon (type in coll. STAUDINGER).

E. gerhardi Weeks is a species of which only a few examples have yet been found and was placed by its author in the genus *Caligo*. Upper surface brown, tinged with dark blue except at the costal margin. Under surface reddish ochreous. Costal margin of the hindwing somewhat flattened, at the apex rounded and passing gradually into the strongly undulate distal margin, the latter slightly angled at the middle median vein, anal angle fully rounded, basal area strongly hairy to the middle of the cell. Upper surface brown, a broad, ill-defined stripe, about from the middle of the cell nearly to the distal margin, suffused with blue; the hindmarginal area vaguely yellow-grey, posteriorly with grey-blue gloss, with a large, oval mealy whitish-yellow scent-spot, proximally adjoining the hindmarginal vein. Under surface reddish ochre-yellow, basal area and the zone behind the cell as far as the distal margin rather uniformly and finely striated with blackish. A transverse band in the middle of the wing vaguely red-brown, distally not sharply defined, proximally distinctly bounded by a silver-white transverse stripe which forms a continuation of the white band on the forewing. The stripe fades out posteriorly at a raised spot which indicates the scent-scale spot of the upper surface. In the cell, touching the stripe, there is an irregular zigzag marking, two pointed oval figures follow at the end of the cell, and in its anterior angle is placed a white spot. ♀ still unknown. Bolivia, Ecuador (Sarayacu). — In **pusillus** Stich. the ♂ is smaller than in the preceding form; the violet-blue dusting lighter and somewhat more distinct, broader on both wings, especially posteriorly and towards the apex of the forewing and the distal margin of the hindwing. The latter more obtusely angled at the middle median vein, apex of the forewing likewise somewhat more obtuse and less produced. Paraguay, Rio Grande do Sul. MABILDE bred *pusillus* on one occasion. The ♀ laid in captivity on the 1st of November 10 eggs, from which after 8 days emerged larvae of dark green colour; these moulted within 15 days, repeating this four or five times down to the 14th January and for the last time on the 4th March. The pupal stage, however, lasts only 13 days, while the larvae feed sometimes for 2 months, occasionally even for 4. The pupa somewhat resembles that of *Caligo martia*, but is more delicate, more compressed, of lighter colour, with a slight rosy gloss and separated light patches. The butterfly flies in Rio Grande throughout the summer and autumn, inhabits the forests and bamboo district, but is nowhere common.

7. Genus: *Caligo* Hbn.

To this genus belong the most imposing forms of the whole family, which equally with the *Morphids* contribute to the character of the South American insect fauna, as some species are even among the commonest butterflies throughout the whole region. They are noteworthy not only for their gigantic size and the peculiar, mostly dull but nevertheless often very rich colouring of the wings, but also for their crepuscular habits, which do not fail to impress even the layman. Structurally *Caligo* nearly approaches the genus *Eryphanis*, with which it agrees in the small precostal cell of the hindwing, notwithstanding the gigantic size of the species. The *Caligonids* differ, however, from *Eryphanis* in the longer and more distinctly angled middle discocellular of the forewing, and the lower discocellular is steeper, not placed almost transversely. The oval androconial spot at the inner margin of the hindwing which is characteristic of *Eryphanis* is wanting in *Caligo*, but they have in common with the former a bare friction-area adjoining the submedian, either with or without hair-pencil, and anteriorly at the subcostal a more or less distinct mealy spot. The pattern of the under surface reaches in *Caligo* the highest development of all the *Brassolids* and consists of delicate, reticulate, waved figures and striation, arranged in alternately light and dark shades on and in contrast with the yellowish ground. On the hindwing two large, brilliantly marked ocelli stand out very effectively, the anterior often crescentic, placed between the costal and subcostal, the posterior larger and placed between the first two median veins, often extending across them. These ocelli bear in their designs the greatest resemblance to the eyes in a peacock's tail, except that the latter are of a shining blue, whilst in *Caligo* the ground-colour is a beautiful orange, gradually shading off through brown into the deepest velvety black. The brilliant markings of the under surface induced LATREILLE to give to the genus the much more characteristic name of *Pavonia*, which unfortunately has had to sink on the score of priority. — Eyes naked or hairy. Palpus rather large, projecting far beyond the head, anteriorly densely covered with long, appressed hairs, with a hair-tuft dorsally. Terminal joint pointed. Antenna thin and delicate, scarcely reaching $\frac{1}{2}$ the length of the wing, only gradually thickened towards the end. Forewing with strong costal vein and 5-branched subcostal, the first two veins arising before the end of the cell, but branches 3 and 4 placed near together almost in the apex of the wing. Cell broad and large, reaching almost to $\frac{2}{3}$ of the wing, all 3 discocellulars well developed. Upper discocellular nearly as long as the lower. Larva slender, slightly arched in the middle, head with two to eight horns, some of which bear bristles. Abdomen produced into two points. Dorsum with five or six false spines. Ground-colour whitish or brown, frequently also green, always with both lateral and dorsal stripes. Favourite food-plants bananas, also *Marantaceae*; larva as a rule on the underside of the leaves, feeding chiefly at night, in the later stages hiding between dry, hanging leaves. Pupa moderately broad, a little narrowed anteriorly and posteriorly. Dorsal edge mostly strongly projecting. Colour yellowish to brown or reddish, on the wing-cases sometimes silvery spots. Pupal stage 20—25 days, but in some species of shorter duration. The imagines inhabit exclusively the dense forests, where they keep near the ground and by preference at the foot of the old trees. They are crepuscular butterflies which are only rarely met with by day. But if one happens to start them up they hide themselves very cleverly in the thickets and on the tree-trunks with the wings folded, and thus find protection. On the Amazon Dr. HAHNEL once observed a bird chasing a *Caligo eurilochus*, but the butterfly eluded the beak of its pursuer again and again with incredible dexterity, as it flew from one thicket to another, until at last the hunted insect was concealed in the thickest confusion of branches and the tired bird had to desist from further pursuit. Profiting by the habit of the *Caligos* of frequenting those places where fallen fruit is lying, one can bait them with bananas, and I often succeeded in this way in capturing 20—25 examples of *C. beltrao* in one day. Some species, such as *C. martia*, visit bleeding trees, where they often sit for hours at the exudations. Occasionally on especially sultry days they even leave the wood and rest at its edge or on the road, and on the Capivary River in Santa Catharina I once found whole columns of *C. beltrao*, which, arranged like outposts, sat in long lines, one near to another, so that I did not know which to take first. In Colombia *C. oileus* Fldr. was met with on mule dung.

Like all large-winged species the *Caligos* nowhere ascend above the densest vegetation zone and it is probable that they never reach beyond 1000 m. above sea-level. Consequently they prefer the tropical zone, with a few offshoots into the subtropical region. Northwards some forms extend as far as Mexico, southwards to Paraguay and Bolivia. According to GODMAN and SALVIN two groups may be separated on the ground of the copulatory organs. 1) *C. oileus* and *eurilochus* group with the valve simply dentate dorsally. 2) *C. atreus* group, valve with a dorsal, medial process, which itself is again dentate.

I. Sect. *Anagraphii* Stich.

Hindwing of the ♂ without hair-pencil on the bare friction-area at the hindmargin.

C. oedipus, a very rare, insignificant-looking species, splits up into two local races: *oedipus* *Stich.* *oedipus*. ♂: forewing above whitish, costal margin slightly darkened with grey-brown, broadly in the cell, distally more narrowly and before the fork of the last subcostal veins running out into a point. The veins in the anterior median area finely dusted with brown. A slight bluish tinge below the cell. The light band behind the cell indistinctly defined proximally, anteriorly strengthened by a nearly saffron-yellow patch. The distal area fairly uniform black-brown, the band near the margin of the wing only quite faintly indicated. The basal area of the hindwing grey-blue to about the end of the cell, obliquely bordered posteriorly, this part as well as the hindmarginal area nearly to the anal angle with blue reflections. Distal margin strongly undulate. ♀ larger, costal area clouded with deeper brown, the bluish tinge below the cell somewhat increased, the light transverse band behind the cell broader and more distinct, the veins very strongly dusted with brown, the spots in the anterior part of the dark brown distal area distinct, the light band before the distal margin better expressed, undulate, slightly dentate. The blue basal area of the hindwing more truncate, with a silky grey-blue gloss, at an oblique angle of light iridescent, the iridescence, however, not extending so far towards the hinder angle as in the ♂. *nocturna* *Stich.* is a subordinate form, in the ♂ of which *nocturna*. the forewing is almost uniformly darkened with smoke-brown as far as a somewhat lighter transverse stripe beyond the cell, the blue gloss restricted to the proximal part of the terminal area. The blue basal area of the hindwing somewhat reduced. Forewing of the ♀ with stronger and more extended blue gloss and duller but more distinct dentate band near the distal margin. Ground-colour in general even darker brown. Transitions occur to the type-form. Colombia. — *fruhstorferi* *Stich.* (64 c) is in the ♂ somewhat smaller on an average than the preceeding; forewing somewhat more rounded, costal area lighter brownish, transparent, but broader and entirely filling up the end of the cell. The confused figures in the cell beneath distinctly visible above, the light transverse band behind the cell better defined, the bluish dusting below the cell somewhat more copious and extended to the inner boundary of the transverse band, which shows through from the underside. The band before the distal margin likewise somewhat better expressed. Hindwing uniformly rounded, distal margin only quite weakly undulate. The blue basal area viewed from above with a silky gloss, in an oblique light with blue reflections for about the same extent as in typical *oedipus*. Under surface with the posterior eye-spot relatively larger. Costal area of the forewing in the ♀ likewise darkened as far as the light median band, strongly transparent, the blue suffusion behind the cell more distinct, also extended on to the anterior part of the cell, but there weaker. The band behind the cell anteriorly strongly dentate, posteriorly feebly curved, the spots in the costal part of the distal area very distinct, the band before the distal margin almost whitish yellow, its boundary strongly dentate, the distal margin itself pale ochre-brown. The blue basal area of the hindwing reaches distally to beyond the end of the cell; viewed from above strongly glossy, in an oblique light with bright blue reflection. Distal margin of the hindwing likewise very little undulate and somewhat more copiously dusted with grey-white. Under surface as in the ♂, except that the dark-shaded band in the middle of the forewing is prolonged to the submedian and the two undulate or dentate bands in the distal area of the hindwing are very sharply expressed. Honduras, probably also in other parts of Central America.

C. oileus is a protean species which seems to be distributed from the Andes to Mexico, southwards reaching Bolivia, but on the Atlantic side apparently not extending beyond Venezuela. Six or seven known races, some of which are not very sharply differentiated. — *oileus* *Fldr.*, the name-type, came from *oileus*. Venezuela. Forewing in the ♂ almost brownish grey, posteriorly somewhat lighter, markings of the under surface showing through. The band before the distal margin washed-out, but always remaining visible. The rest of the marginal area distally pale black-brown, the dark spots in the apical area distinct, the light band basally more or less distinctly projecting along the veins; the blue gloss below the cell weak, often only perceptible in an oblique light. ♀ larger, wings smoke-brown to the narrow transverse band, basal part to near the costa and to the posterior part of the cell slightly suffused with bluish, rather strongly glossy, the rest as in the ♂, but with the band before the distal margin more distinct. Under surface with moderately widened whitish band behind the cell of the forewing. Hindwing with distinctly developed dentate band in the distal part. The submarginal lines on the underside of the forewing in both ♂ and ♀ shortly and regularly dentate. Venezuela. — *scamander* *Bdv.* has the apex somewhat produced. Costal area darkened as far as the median, the anal area relieved with whitish grey; only at the base a faint blue gloss. Transverse band as a rule rather broad, anteriorly narrower, bone-white, quite faintly tinged with yellow. Markings of the under surface showing through above. ♀ larger, wings more rounded, transverse band widened, especially beneath, its boundary-line curved distad. Anal area as far as the transverse band somewhat darker and more copiously shot with blue. Distal margin of the hindwing somewhat less undulate, the proximal area viewed from above somewhat more distinct but paler blue-grey. On the under surface the undulate band behind the cell of the hindwing especially sharply expressed, with metallic black-blue gloss. In both sexes the lines near the distal margin on the underside of the forewing less regular and more shallowly curved than in the typical subspecies. Central America (Costa Rica, Panama [?], Mexico [?], Guatemala [?]). — *philademus* *Stgr.*, from the *philademus*. province of Antioquia in Colombia, closely approximates to *scamander* and likewise to *oileus* *Fldr.* from Venezuela, but is darker, hindwing above more strongly shot with greenish blue. ♂ under surface with deep brown median area, ♀ scarcely lighter in the distal area. From the Cauca Valley, in coll. FRUHSTORFER. — *phorbas* *Röb.* is somewhat more brightly coloured than the typical *oileus*, the band behind the cell of the forewing *phorbas*.

consequently standing out more distinctly and in general somewhat less dentate; the basal and hindmarginal areas somewhat more strongly tinged with blue. ♀ without appreciable constant differences from that of the *umbratilis*, preceding subspecies. Ecuador. Type in coll. FRUHSTORFER. — In *umbratilis* *Stich.* the ♂ is darkened with smoke-brown above, the blue tinge behind the cell of the forewing only weak, rarely somewhat stronger. The transverse band distally to the cell washed-out, occasionally, however, distinctly expressed; in the latter case anteriorly narrow, whitish, posteriorly somewhat widened, yellowish and terminating at the posterior median vein. The band near the distal margin likewise more or less distinct, the dark spots at the costal margin near the apex well developed. Under surface very sharply marked and with much white in the ground-colour, particularly *philinos*, in the distal part of the hindwing. Peru. — *philinos* *Fruhst.* (65 a). ♂ somewhat smaller and less slender than *scamander*. Forewing grey-brown, copiously shaded with blue. The yellow area of the forewing reduced to a narrow but distinct band. Ground-colour darker, particularly on the forewing. The hindwing, however, more narrowly margined with black, on the other hand with broader distal border, grey in the ♂, yellowish grey in the ♀. Under surface: the brown discal band of the hindwing narrower, the yellow submarginal zone broader and lighter, the discal band of the forewing considerably narrower. Bolivia.

zeuxippus. **C. zeuxippus** *Druce* (65 b) inhabits Ecuador. Under surface somewhat resembling that of *oileus*. It is noteworthy for the strikingly light basal area, particularly on the hindwing, which is delicately striated with white. The ocelli are placed in a light coffee-brown median area, which again is surrounded by a zone of light striation.

placidianus. **C. placidianus** *Stgr.*, originally described from Sarayacu in Peru and from São Paulo de Olivença on the Upper Amazon, is a very large species with broad, unmarked, dark distal border on the forewing, before which an undecided yellowish band, distally rather sharply defined, runs to the posterior median. The ♀ has the basal half of the forewing blue-grey, bounded by a still more indefinite yellowish grey band. Under surface very similar to that of *C. oileus*, but at once distinguishable from this and indeed from all other known species by a deep brown area running from the posterior to the anterior median along the cell-wall and anteriorly narrowed; this occurs also on the hindwing, but there covers the entire middle of the wing, is sharply cut off proximally, but considerably widened distally about the anal ocellus. Cell of the forewing covered with elegant black markings looking like cumulus clouds. *micans* *Röb.* describes a slightly modified local form from Ecuador in which the basal half of the hindwing above has a somewhat more intensive gloss.

beltrao. **C. beltrao** *Ill.* (= *demosthenes* *Perry*, *inachis* *Godt.*) (65 b) is one of the most brilliantly coloured species of the genus and among the characteristic butterflies of central and southern Brazil. All day long they remain in the lower brushwood or round the trunks of the forest giants, where they hide near the ground. Only in the evening twilight or in the early morning, before the daylight has dispersed the last shadows of the night, they come out of their hiding-places for a short time. One can then sometimes see them sitting on the road in large numbers. In Santa Catharina in the valley of the Capivary River I observed that the butterflies were positively common on sultry days and one might with truth speak of whole regiments of *Caligo*, of which the outposts were arranged at the edge of the woods and at such short distances that one hardly knew which to take first. *beltrao* can also be attracted with bananas and it was a pretty sight to see the giant *Caligos* hanging on the bait in living clusters in company with *Dasyophthalma creusa*, *Eryphanis reevesi* and *Prepona meander*. ♂ beneath predominantly irrorated with a fine coffee-brown, with very broad median area of the same colour, which traverses both wings, changes into black beyond the cell and is distally bordered by a zone of whitish and purple dusting. Hindwing with the anal ocellus shaped like a hazel-nut with the point placed posteriorly, the ocellus margined with a beautiful light yellow. The ♀ larger, wings broader, more rounded, colouring duller. Apex of the forewing light ochre-yellow, only proximally somewhat tinged with orange, the dirty yellow marginal stripe broader, gradually narrowing to the anal angle. The white costal spot in the yellow area very conspicuous, the adjoining distal black dusting in the apex more distinct, condensed into a double spot with white sagittate or lunulate spots accompanying it. Under surface somewhat lighter, the band-like brown shading in the middle of the forewing behind the posterior median vein more distinctly prolonged; close to the distal margin run two blackish parallel lines, which are anteriorly somewhat more delicate brownish, have whitish and yellowish bordering and are gently curved, but behind the eye-spot project basewards near the apex and then run to the anal angle in large, sharp teeth, some of which are bidentate. On the hindwing the bands beyond the cell better expressed, the distal margin more broadly brown and with a second dentate band similar to the first-named, but less distinct. Abdomen with lighter grey-blue hairs. — Larva on bananas, like that of *C. eurilochus brasiliensis* green when young with elongate brown dorsal spots and a white and brown lateral stripe. The spots disappear later and the ground-colour becomes green; in the adult stage the caterpillar is dirty green to yellowish brown, irregularly shaded with black, laterally with a pure white stripe, edged with black at both sides, along the stigmata; the body tapering anteriorly, on the dorsum with soft warts (false thorns), the head with a crest of eight horns. Pupa in size and markings in general like that of *eurilochus*, but paler and without bristles (W. MÜLLER). The ♂ figured came from Rio Grande do Sul, where *beltrao* has become

very rare. Also in Rio de Janeiro the species is no longer very common, but it apparently occurs in larger numbers in Espiritu Santo. Examples from there are by far the largest, somewhat lighter blue, and both sexes have the apical spot on the forewing paler yellow and more extended than in my Santa Catharina specimens. Moreover the basal area on the underside of the hindwing is appreciably lighter and in the ♀ the distal border of the brown median area is much lighter, one might almost say pure white. According to BURMEISTER *beltrao* also occurs in Argentina, but I do not know any Argentine examples in nature.

II. Sect. *Graphiophori* Stich.

Hindwing with a small hair-pencil on the bare friction-area at the submedian.

C. teucer, one of the most inconspicuous species, is distributed over the entire region in which the *Caligos* occur with the exception only of Central America and Mexico. *teucer* is less susceptible to climatic influences than other species of the genus and consequently only splits up into a small number of not very sharply differentiated local forms. — In *insulanus* Stich. the costal area of the forewing in the ♂ is of an indefinite light grey, not or scarcely brownish, the yellowish white transverse band distally to the cell very narrow and dull, the triangular hindmarginal area grey-blue fully to its anterior limit, also the cell for about half its breadth with a vague grey-blue tinge. The distal marginal area blackish, the undulate lines near the margin only quite indistinctly showing through and only slight traces of a band present between them. Basal area of the hindwing grey-blue, in an oblique light with violet-blue reflection in its distal part, extending nearly to the end of the cell, distal half of the wing blackish with quite fine whitish border. The ♀ larger, the band of the forewing somewhat broader, anteriorly more or less dusted with dark, from the posterior angle of the cell onwards purer whitish yellow, posteriorly again blurred. The blue dusting of the hindmarginal area is continued anteriorly in the cell, only leaving a narrow costal stripe. The band near the distal margin of a very fine and distinct whitish yellow, the proximal boundary strongly curved and very sharp, the distal less strong, but distinctly defined by a dark-dusted stripe. Hindwing with the basal area widened, distally likewise with a beautiful iridescence. This extends to beyond the cell and to the hindmarginal vein. Distal margin of the hindwing somewhat more strongly dusted with whitish than in the ♂; abdomen with bluish gloss. Trinidad. — *suzanna* Deyr. *suzanna*. is a dark subspecies; forewing from the hindmargin nearly to the costal margin and the narrow whitish band tinged with blue. Marginal area almost black, the submarginal undulate line not conspicuous, the margin itself strongly undulate, quite finely edged with whitish. Hindwing velvety black, distal margin finely whitish. Basal area greenish to near the end of the cell or even somewhat further and nearly to the anal angle, at its extremity with clear blue reflections. Under surface strongly and copiously marbled with brown and black-brown. In the posterior median cellule of the forewing is placed a small, rather distinct eye-spot, a larger one near the apex. The ring round the posterior eye-spot of the hindwing is very light yellow, nearly white, laterally and posteriorly more yellow, at the outer margin changing into rust-yellow. The brown band-like colouring between the anterior and posterior eye-spots only persists as a narrow, sometimes quite indistinct stripe running through the cell, the smaller oval patch distally to the middle discocellular more or less distinct. The ♀ has broader wings, otherwise quite similar. In the forewing the light band running between the marginal lines near the distal margin and the black spots at the costal margin near the apex more distinctly expressed. The blue reflection on the hindwing extended somewhat beyond the end of the cell. On the under surface the hindmarginal area of the forewing to the submedian striated, like the rest of the wing, the small posterior eye-spot in the distal area absent. In the median area of the hindwing the brown band-like shading better developed, in the cell a distinct elongate light patch. In general the striation and marbling on the entire surface of both wings somewhat coarser and darker. In transitions to the typical subspecies, not locally constant. Colombia. — *phorkys* subsp. nov. differs from *phoroneus* Fruhst. in the narrower, washed-out yellowish grey longitudinal band of the forewing, which is broken up into separate spots and is also distinguished at once from *suzanna* Deyr. by the isolated patches. Under surface lighter than *phoroneus*, particularly the basal part and the distal area of the hindwing. Coroico, Bolivia, 1200 m. — In *teucer* L. *teucer*. the costal area of the forewing is broadly grey-brown, cell also grey-brown except a narrow stripe in the posterior half. The brown area is approximately spindle-shaped with the points placed at the base of the wing and at the costa before the fork of the 4th and 5th subcostal veins. The transverse band beyond the cell begins 3—4 mm. in width, is distinct to the angle of the cell, then only sharply defined distally, and terminates at the posterior median vein. In the middle and posterior median cellules it forms two shallow curves. The light grey median area is widened posteriorly and forms a long acute-angled triangle to the hindmargin. Posteriorly the colour becomes a trifle darker, particularly at the base of the wing, and is slightly tinged with bluish. The distal area, for an average breadth of 18—19 mm., is dark to pale smoke-brown, fringes and a quite fine marginal stripe dirty white, the submarginal lines of the under surface show through, and between them there is a very faint, somewhat lighter undulate band, which scarcely contrasts at all in colour with the extreme marginal area and is only separated from this by the distal line, but on the other hand is proximally more distinctly defined by the darker median area. Posteriorly the marginal markings become quite blurred and the colour assumes a uniformly dark tone for the whole breadth of the distal area. Hindwing black-brown, the fringes from the apex nearly to the hinder angle whitish, basal area behind the grey costal zone grey-blue, in an oblique light

greenish, distally with violet-blue reflection. This reaches in the cell about to its middle, below it to two-thirds of the hindmargin and is gradually lost in the ground-colour. In the costal area of the hindwing and on almost the whole of the forewing the dark markings of the under surface show through slightly. Under surface rather coarsely and profusely marbled, forewing with two eye-spots. The ♀ is larger, the bluish colour below the cell of the forewing weaker, the light band beyond the cell broader, the undulate band between the strongly dentate lines which show through from beneath near the distal margin standing out more distinctly. The blue on the hindwing further extended, deeper in tone, with less greenish reflection. In the Amazon region extending towards the west and north-west (Peru, Colombia), this race becomes transitional towards *C. teucer suzanna*, being more brightly coloured, with a somewhat darker costal area on the forewing and more copious blue dusting at the hindmargin, while the hindwing shows a more extended blue basal area. Guiana, northern

nubilus. Brazil, western Peru. — **nubilus** *Fruhst.* (63 c). Band distally to the cell of the forewing completely suppressed, ground-colour in the cell especially dark, a dull blue gloss spreads almost uniformly over the whole proximal

obidonus. half of both wings. British Guiana. — **obidonus** *Fruhst.* Paler than the type-form. The blue basal area of the hindwing extended to the end of the cell, hence the distal and anal area more narrowly black-brown. Under surface more marbled with white, in the cell of the forewing with brighter white bands. In the hindwing the posterior eye-spot with smaller black pupil and broader yellow ring, in the cell the white elongate patches standing out very brightly on a brown ground, the oval ring-spot before the middle discocellular on the other

japetus. hand more weakly coloured. Amazons (Obidos). — **japetus** *Stich.*, from Paraguay, has broader wings than typical *teucer*; the spindle-shaped brown costal area widened so as only to leave free the extreme distal angle of the cell, which assumes the colour of the adjoining transverse band. This is almost ochre-yellow, posteriorly somewhat paler. The triangular grey area behind the cell, which posteriorly to and in continuation of the transverse band is bounded by the dark brown distal area and anteriorly reaches to the origin of the middle median vein, is shot with bluish throughout, and a narrow posterior stripe in the cell is also slightly tinged with blue; in an oblique light this dusting shows a beautiful sky-blue sheen. The light transverse band between the curved lines which show through from beneath near the distal margin more distinct and proximally in particular standing out very sharply against the dark area. Blue basal area of the hindwing extended to the end of the cell and nearly to the hinder angle, in an oblique light with brilliant violet-blue reflection. The strongly undulate distal margin profusely dusted with whitish, particularly at the incisions. Under surface in general with somewhat lighter ground-colour, the distal half of the hindwing in particular with strong whitish admixture. In the forewing only one eye-spot, near the apex. ♀ larger; the bluish tinge on the forewing spreads over almost the entire cell, but is somewhat less pronounced. The band behind the cell broader, anteriorly, in the radial interspaces, with pointed, wedge-shaped teeth proximally. The band near the distal margin dirty ochre-yellow, more distinctly defined, distally in particular bordered by a stripe more strongly dusted with black-brown. Hindwing with the basal area considerably widened, in an oblique light with brilliant violet-blue and greenish reflections. It extends about 6—7 mm. beyond the end of the cell, nearly reaching the anal angle. Under surface somewhat less brightly and more coarsely marked. Thorax and abdomen strongly dusted with grey-blue.

phoroneus. — **phoroneus** *Fruhst.* This local race, with the upper surface strongly darkened, forms a transition from the light forms of the Lower Amazon region to the dark *suzanna Deyr.* from Colombia. The light yellowish area which in *teucer* and *obidonus* *Fruhst.* spreads over a third of the forewing is reduced to a rather sharply defined, narrow dark yellow band, which in the ♂ still covers the extreme apex of the cell on the forewing. In the ♀ this band is even more narrowed and runs beyond the cell, gradually becoming darker and terminating before the 3rd median vein. The cell of the ♂♂ is darkened with the exception of the apical and lower parts, that of the ♀♀ entirely darkened, and shot with deep blue. The hindwing except the black distal margin with as dark blue gloss as in *euphorbus* *Fldr.* The large ocelli on the underside of the hindwing characterized by having a brown border, which is much more extended than in *teucer* and *obidonus*. Jaupes.

C. illioneus occurs together with *teucer*, but its range extends somewhat further south on the Atlantic coast and it is still met with at Rio de Janeiro, where according to BÖNNINGHAUSEN it occurs on the north side of the bay at Piedade. Unlike *teucer*, its early stages are well known. Larva on bananas. Northwards *illioneus* extends as far as Panama. Such localities as Guatemala and Mexico are no doubt due to errors in determination, it having been confused with *memnon*, which is everywhere common in those countries. —

oberon. **oberon** *Btlr.* ♂, very dull-coloured, the blue of the forewing in the costal and posterior part of the cell very faint, the posterior angle of the latter entirely free, the reflection strong but darker. Transverse bands dull, sometimes even indistinct. The proximal one as a rule only somewhat more distinct anteriorly, from the radials onwards obsolescent, the distal sinuous, the costal curves more, the anal less strongly diffused on either side of the veins in such a way that the rays are as a rule united anteriorly with the smaller curves of the proximal band, forming elongate ring-spots in which are enclosed oval spots of the dark brown ground-colour, sometimes proximally truncate. This formation, although it occurs more rarely also in single individuals of other subspecies (particularly in *C. i. polyxenus*), is in general very characteristic of *oberon*. ♀ paler, with the same peculiarities, the transverse bands of the forewing somewhat lighter, the markings of the under surface showing through more strongly. Panama. — **praxsiodus** *subsp. nov.* is before me in four examples from different

parts of Peru. It approximates in its small size to the Trinidad race and differs from the type-form in the brighter, more brilliantly glossy reflection on the basal part of both wings, which are also traversed by very narrow inconspicuous longitudinal bands. By these *praxiodus* may also be at once separated from *pampeiro* *Fruhst.*, in which the bright ochre-yellow longitudinal bands are always conspicuous. Under surface very closely resembling *oberon* *Bltr.*, but with still darker striation, the anal eye-spots very much smaller, the whitish dusting in the median and submarginal areas nearly obsolete. — ***pheidriades* subsp. nov.** ♂ somewhat smaller than *pheidriades*. *oberon* *Bltr.* from Colombia, but more brightly coloured, not only more glossy blue but also with a stronger yellow submarginal band on the forewing than that form and *pampeiro* *Fruhst.* from Paraguay. Under surface very characteristic on account of the sharply contrasting bands, alternately brown or whitish grey, which traverse the hindwing in particular. The arrangement of the band-like areas as in *oberon*, but the colouring more of the brown tone of *praxiodus*, all the light areas, however, more extended than in Peru ♂♂. Ocelli of the hindwing considerably larger than in *praxiodus*, with the bordering much lighter, nearly whitish yellow. Coroico, Bolivia, from 1200 m. — ***saltus* Kaye** is always smaller than *polyxenus*, the ♀ especially *saltus*. with the bands of the forewing more grey instead of brightly coloured. Egg (according to KAYE and GUPPY) spherical, whitish, with regular longitudinal ribbing. Young larva whitish, dorsal surface with 2 red double stripes at the sides, head large, brown, strongly hairy, a long, branched tail-fork; after the first moult the head more slender, reddish, with branched horns; upperside of the body green with a brown stripe and a white upper lateral longitudinal line, below the stigmatal line striped with white and reddish. Tail-fork simple, on the 6th segment a thorn-like point. After the second moult the body becomes brownish, with two dorsal points on the 6th and 8th segments, and shows an upper lateral stripe and on the separate segments brownish oblique stripes decreasing posteriorly; stigmatal lines as before. The full-grown caterpillar is cylindrical, tapering anteriorly and posteriorly; head broad, flat, obliquely sloping anteriorly, striped with black-brown, with 2 pairs of shorter and 1 pair of longer horns; the first segments of the body strongly grooved transversely, on the dorsum two short points; ground-colour of the body dirty white, dorsal stripe blackish, anteriorly cleft, at both sides an upper lateral dark double line, below this a greenish lateral stripe, from which on the separate segments oblique stripes ascend anteriorly, below it a reddish brown stigmatal stripe, bordered with white on both sides. Ventral surface and legs dirty green, fork shortened. Entire length 115 mm., length of the fork 9 mm. Trinidad; St. Vincent (British Museum). — ***polyxenus* Stich.** Transverse bands of the forewing somewhat widened and particularly bright ochre-yellow, more rarely somewhat darker. The band at the cell anteriorly somewhat dentate, then nearly straight, proximally but little incised at the veins. The band near the distal margin strongly zigzag, anteriorly the separate teeth more or less diffused proximally on the veins. Distal margin of the hindwing anteriorly more broadly, posteriorly narrowly dusted with whitish. On the underside of the hindwing the posterior eye-spot is as a rule especially large and broadly ringed with whitish yellow. — In ***ilioneus* Cr.** (64 c) the ground-colour of the ♂ is in general more dusky, but the wings have a strong blue gloss. Cell of the forewing mostly shot with blue throughout, costally and basally paler, almost grey-blue. Transverse bands ochre-yellow, the tone of colour inconstant, mostly not quite pure, sometimes even strongly darkened, both on the whole narrow, the one adjoining the cell somewhat dentate anteriorly, from the lower radial onwards nearly straight; it terminates at the lower median vein and its posterior part is obsolescent. The submarginal band anteriorly somewhat sinuous, then at most slightly undulate and in its general course but little curved. This also is somewhat more indistinct posteriorly, likewise terminating at the lower median vein or somewhat before it. The blue basal area of the hindwing extended to beyond the end of the cell and nearly reaching the hinder angle, strongly iridescent, but paler anteriorly. On the subcostal, close to the precostal cell, is placed a flattened, blackish scent-scale spot, with somewhat bluish reflection in a side light, which extends on to the cell. Fringes of both wings whitish yellow, distal margin of the hindwing not at all or only quite narrowly dusted with whitish. ♀. Considerably paler in colour. Forewing less dusted with blue, the transverse bands lighter, broader, sometimes more strongly dentate and undulate. Hindwing with broad grey-brown or dirty whitish costal area, in which the striation of the under surface shows through more distinctly. Hence the blue basal area is somewhat restricted anteriorly. Distal margin of the hindwing somewhat more, but still only slightly dusted with whitish. Larva very similar to that of *C. eurilochus*, but smaller and proportionately thicker. Body with fine transverse grooves, on the dorsum with 6 weak, spine-like points, otherwise covered with short, stiff hairs. Ground-colour yellow-brown with black dorsal line, which is forked anteriorly. The body laterally striped with alternate light and dark brown and on the upper half with short brown oblique stripes. Ventral surface dark brown. Head of the colour of the body, with five broad dark stripes. Pupa compact, suspended, at the vertex with narrow helmet-like comb, of yellowish ground-colour, marked with brown, with two very conspicuous silver spots on the wing-cases. Guiana, Brazil, Amazons, Pará, Rio de Janeiro. Examples from Rio de Janeiro are wanting in my collection; there are some from Pernambuco in the British Museum. — ***pampeiro* Fruhst.** is smaller, lighter, the blue reflection stronger, but the blue dusting on the forewing somewhat reduced, the distal part of the cell mostly remaining brown. Transverse bands pure orange-yellow, the proximal but little sinuous or dentate, posteriorly somewhat duller, the submarginal more strongly sinuous and dentate. Distal margin more strongly excised, border of the hindwing very broadly dusted with yellowish white in curves. The large ocellus on the underside of the hindwing shows a tendency to posterior elongation. ♀ paler, the bands on the forewing lighter, the submarginal broader. Distal margin of the hindwing bordered with white, in the interspaces between the veins broad yellow-white crescentic spots. Paraguay.

C. prometheus somewhat resembles *C. memnon* (65 a) above, but is considerably larger, the basal part of the forewing more extended pale yellowish, that of the hindwing more richly suffused with blue. Range, so far as is at present known, confined to Colombia and Ecuador. **prometheus** Koll. On the forewing the grey dusting in the costal area at and behind the end of the cell is reduced to a narrow stripe, which is only towards the end, before the fork of the fourth and fifth subcostal venis, a trifle widened. Hindwing in an oblique light with intensive blue reflection, at the base greenish, from the end of the cell to the distal margin a beautiful azure blue; the sheen decreases somewhat in strength anteriorly, but leaves only the apical area and a costal stripe free. Under surface of the forewing copiously striated; behind and distally to the cell, starting from its posterior angle, are placed two connected blackish arcuate spots, mostly very distinct and sharply expressed, bordering the light transverse band proximally. Colombia; Nicaragua (?). — **epimetheus** Fldr. is a lowland form from eastern Colombia. Somewhat smaller than the type-form, the grey dusting at the costal margin of the forewing broader, on the other hand the blue colour on the hindwing confined to the proximal half, in an oblique light less iridescent, but viewed from above more distinctly defined. Colombia: Rio Aquara Valley, West Cordilleras, 2000 m. The egg is almost as large as that of *Saturnia pyri*, round, somewhat flattened at both poles, the sides with longitudinal grooves, which again are divided into cells by horizontal belts. Towards the base these are broken up into smaller and smaller dots and finally terminate in a smooth surface. The apex of the egg forms a wart-like elevation of brown colour, the micropyle is placed somewhat at the side. The larva is of the shape of the typical *Caligo* larva figured in SCHATZ. It is brown-grey, on the dorsum with three lighter angular markings, the vertices of which run back into the mediodorsal line. Many specimens attain 13 cm., these mostly yielding females. I found the larvae always in small companies of up to 8 specimens on the lower end of the stalks of Platanillos (wild bananas), or hidden in dry leaves; they only feed at night and always return to their old place, where they mostly sit closely packed together. The pupa is very similar to that of *Cal. eurylochus*, ornamented with a silvery shoulder-spot. The pupal stage lasts 4 weeks. In breeding the number of specimens of the two sexes was about equal. — **anaximandrus** Fruhst. Replaces the small lowland form *epimetheus* Fldr. of eastern Colombia in the transandean region, and is also of small habitus. The ♂ approaches *atlas* Rüb. from Ecuador, with which it entirely agrees above except that the black marginal band of the forewing is somewhat more sharply defined proximally. The under surface, however, differs considerably in the more lively, brightly contrasted colouring. The submarginal black hatching on the forewing is almost absent, the bordering of the ocelli is light red-brown instead of nearly black. Hindwing with brown instead of nearly black foreground to the anal ocellus, the eye-spots themselves scarcely half as broadly margined with black. The distinct black-striated submarginal band of *atlas* is wanting; in general the entire distal area of the hindwing is whitish watered with yellowish. Basal part likewise predominantly whitish instead of black. The ♀, unlike the ♂, is distinctly modified above also and especially characterized by the yellowish area extending as a sharply defined band to the costal margin. Compared with *atlas* Rüb. from Ecuador this light part of the wing is altogether more pronounced and contrasts sharply with the black terminal area, which is proximally very neatly undulate, with distinct but not deep incisions. Hindwing somewhat more richly coloured, distally of a finer whitish yellow than in *atlas*. Under surface: coloration gayer, the distal area in particular striated with yellow rather than brown-black. The brown bordering of the anal ocellus, which touches the black ring, scarcely half as broad as in Ecuador ♀♀. This handsome new West Colombian form was discovered by A. H. FASSL on the upper Rio Negro at an elevation of 800 m. — **atlas** Rüb. Forewing of the ♂ rather narrow, apex more pointed, distal margin of both wings more strongly undulate than in the preceding, otherwise similar on the upper surface to *epimetheus*. Costal area of the forewing broadly grey-brown, towards the end of the cell but little narrowed and distally to this again widened as far as the middle discocellular, the blue-grey basal dusting behind the cell on the contrary somewhat reduced. Beneath the striation and other markings more sparse, the dark curved transverse line behind the cell being absent or only weakly indicated and the space immediately behind the distal half of the cell and part of the cell itself only quite finely watered with gold-yellow. Consequently the upper surface, on which the dark markings show through in the whitish areas, is purer white beyond the cell as far as the posterior median vein. On the hindwing the blue reflection weaker and only extending to towards the end of the cell and towards the hinder angle. At the distal margin occasionally a further quite faint bluish gloss perceptible in places. On the under surface the ground-colour more white or bluish white, but the striation coarser and darker, the curved bands near the distal margin as a rule only indistinct or not developed at all, the posterior eye-spot mostly somewhat smaller than in the preceding. Ecuador.

C. memnon may be regarded as the most northerly *Caligo* form, is at home exclusively in the Central American and Colombian-Venezuelan subregions of the *Caligo* area and southwards apparently does not occur even in Ecuador. *memnon* is considered one of the commonest butterflies of Mexico and Guatemala and is represented in every consignment from the tropical parts of those countries. Notwithstanding this we have no information concerning the early stages. **memnon** Fldr. Under surface of the forewing mostly only sparsely striated in the cell. In addition to some irregular dark brown zigzag and undulate lines and some brownish clouding the surface of the wing is finely watered with reddish yellow, sparingly beyond the cell. The dark nebulous band

distally to the cell always distinct, but from the end of the cell onwards becoming weaker or entirely absent. Hindwing in the basal area striated coarsely with white and dark brown, in the distal area finely and uniformly with bluish white-grey and brown. The median area with the 3 eye-spots strongly brown in ground-colour, the elongate light cell-patch, however, not very conspicuous. The ♀ is larger, with exactly the same markings, but the band near the distal margin of the forewing considerably more sharply expressed. It consists of a row of whitish lunules or crescentic spots, deeply incised proximally at the veins, distally less sharply defined, but still distinctly contrasted with the grey-brown distal margin. In the costal part of the dark brown distal area there are mostly 4 rather distinct round black spots in the interneural spaces near the apex. Costal area of the hindwing relieved with grey-white and the distal margin more strongly dusted with whitish. Under surface lighter, the brown zigzag stripes and striation on the forewing reduced; the dark band beyond the cell as a rule narrow but distinct, the darker area behind the transverse band but little striated; in it are placed wedge-shaped, loosely connected dark teeth. Hindwing more coarsely striated, the brown median area less conspicuous, in the outer part a curved band, mostly standing out very sharply. Mexico, Honduras, Nicaragua, Costa Rica (?). — **menes** *Fruhst.* ♂ differing from *memnon* *Fldr.* from Mexico in the darker ground-colour of the wings (particularly in the costal area of the forewing), which is caused by the increase of brown scaling on the under surface. The hindwing with more of the blue reflection, but less intensive than in *telamonius* *Fldr.* The under surface strongly suggests *teucer* in the black discal band of the forewing; the forewing bears, however, larger ocelli than in *memnon* or in *teucer*, and the middle eye-spot, between the radials, is more strongly developed. The ♀ differs from *memnon* and *teucer* in the much narrower, but more sharply defined, black distal border of the hindwing. Chiriqui. — **diluta** *Stich.* Commoner form of the subspecies *menes*. In the ♂ the forewing is almost as in *C. m. memnon*, costal area occasionally even narrower and but little darker than the light, pure white-yellow ground-colour, but the band near the distal margin as in the type-form quite blurred. On the hindwing the blue reflection somewhat more extended, but not reaching the distal margin. It usually disappears at the end of the cell and shortly before the hinder angle, but in all cases a faint bluish violet tinge is perceptible at the distal margin when viewed obliquely, much as in *C. idomeneus*, only not so strong. Under surface variable, usually as in *menes*, but even less marked, the distal half of the cell of the forewing and the adjoining area behind it only delicately watered with reddish yellow and white; only in the posterior projecting angle of the cell some brownish striation is present. The dark transverse band behind the cell then only persists in the anterior part and from the posterior angle of the cell is entirely absent or represented by two slightly shaded lunules. The proximal of the two curved bands near the distal margin again more sharply dentate than in the type-form. Hindwing mostly remaining rather dark, the posterior eye-spot as a rule somewhat reduced. Otherwise without essential differences. ♀: costal area more broadly grey-brown, in the distal half of the cell somewhat constricted, thus better developed than in *memnon* ♀; the band near the distal margin more distinctly defined than in the ♂, but less sharp and not so clear as in *memnon*. Blue reflection on the hindwing about as in the ♀ of this subspecies, even somewhat more restricted. Under surface of the forewing in the distal half of the cell pretty uniformly striated with brownish, the area behind the cell to the lower median vein almost without markings, the dark transverse band distally to the cell here only weakly indicated. Under surface of the hindwing with very close transverse striation, predominantly brown, the median area in particular also broadly pure brown, the light cell-patch very distinctly defined. The eye-spots large and distinct, the middle one rather full and almost round; behind it, in the angle of the lower radial and discocellular, sometimes a small round accessory ocellus. Panama (Chiriqui). — **peleus** *Stich.* ♂: forewing pale ochre-yellow, basal and costal areas rather broadly shaded with light grey-brown, the markings of the under surface showing through rather distinctly. Distally to the cell a narrow transverse band of the ground-colour, distinct as far as the posterior median vein. Distal area nearly black, the margin itself smoke-brown; between the dentate lines showing through from beneath a washed-out curved band, which is only anteriorly somewhat lighter. Hindwing with the distal margin very slightly undulate and quite narrowly dusted with whitish. Blue reflection a beautiful indigo, but only extending to the end of the cell and to shortly before the anal angle. The reflection shades gradually into the deep velvet-black colour of the distal half, which in places still shows some bluish gloss. Under surface sharply and densely striated and marbled. Forewing below the strongly developed anterior eye-spot sometimes with 3 further dark spots placed one behind another. Ground-colour in the cell yellowish white, the light transverse band behind the cell sharply defined basally. Hindwing as in the following form; in the type specimen there is before the middle ringed eye-spot a smaller, brownish accessory ocellus, with white pupil and black border, separated from the former by the anterior radial. Venezuela (Merida). — **telamonius** *Fldr.* ♂: forewing light ochre-yellow. Costal area rather broadly, but only slightly, darkened with grey-brown, markings of the under surface showing through, the light band beyond the cell well distinguishable as far as the posterior median vein. Marginal area brown, the striation of the under surface still traceable. Submarginal band very indistinct. Hindwing with strong blue reflection, but when viewed from above only appearing shot with grey-blue from the base to the end of the cell and nearly to the anal angle. In an oblique light almost the whole wing except the costal area and a spot in the apex shows deep indigo-blue reflections, at the base slightly greenish. Distal margin undulate, slightly dusted with whitish. Under surface very profusely striated and marbled, as in the form *menes*, the distal part of the cell in particular strongly clouded and striated

as far as a light terminal patch, the light transverse band behind it sharply defined proximally by the dark lunulate markings. In the distal area sometimes only a single eye-spot near the apex, the posterior one faintly indicated or likewise distinctly developed. The dark band-like median area of the hindwing, in which the eye-spots are placed, as a rule distinctly defined at both sides. In the distal area at least one sharply curved band composed of dense striation. Occasionally there is a small, light-pupilled accessory eye-spot or a brownish spot before the middle ocellus. A pronounced highland form from Pacho, East Cordillera, 2200 m.,

pavo. Colombia, western Venezuela. — *pavo* Rüb. is a valley form; larger than *telamonius*. Ground-colour deep saffron to gold-yellow, the grey-brown costal area of the forewing somewhat deeper in tone; blue reflection of the hindwing somewhat more restricted than in *telamonius*. Colombia, Venezuela. — *pavonides* subsp. nov. replaces *pavo* Rüb. in eastern Colombia, is likewise a valley form and differs from RÖBER's cotypes in my collection in having the light area of the forewing pale yellow above, more suggesting *memnon memnon*, and in the distinct light blue reflection in the submarginal area. Under surface with the yellowish and whitish parts much more extended and the anal ocelli smaller than in West Colombian *pavo*. Taken by FASSL on the Upper Rio Negro at 800 m.

bellerophon. **C. bellerophon** Stich. (63 c) replaces *memnon* in Ecuador. The under surface apparently does not differ materially from *memnon*, but on the upperside *bellerophon* is distinguished at once from its northern representative by the deeper yellow, slightly greenish-tinged basal area of both wings and by having the distal part of the marginal region brown instead of black. Hitherto only known from Ecuador.

C. eurilochus is probably the best known species of the genus and the most widely distributed in collections. We are also fully acquainted with its habits and transformations. Larva on bananas and other Musaceae. Occurs from Honduras to Santa Catharina and from Colombia to Bolivia. — *sulanus* Fruhst. (63 c), the most northerly branch, is extraordinarily rare in Guatemala and Honduras, but according to GODMAN and SALVIN seems to occur in somewhat larger numbers in Nicaragua. ♂ grey, the basal half of the hindmarginal part of the forewing dusted with blue-grey, somewhat iridescent. Before the marginal area a yellowish band, which is anteriorly distinct and straight, towards the hindmargin washed-out. Distal margin of the forewing dull, dirty earth-brown. Spots near the apex present, but weakly or hardly dotted with white. Hindwing velvety black, finely margined with white, the basal half to $\frac{2}{3}$ of the cell and of the inner margin with blue-green reflection. Beneath almost as *brasiliensis*, somewhat lighter grey than this and the striation finer; in the forewing mostly only one eye-spot, near the apex. The posterior ocellus on the hindwing very sharply expressed, the bordering almost saffron-yellow. ♀ dark grey, copiously tinged with blue, the markings of the under surface showing through strongly, the whole of the distal markings sometimes washed out and indistinctly clouded, in any case not so distinctly expressed as in *brasiliensis*. Central America. — In northern Colombia *sulanus* is replaced by *galba* Deyr. The ♂ is similar but paler, the transverse band at the cell only quite weakly indicated by the pattern showing through from beneath, more weakly than in *sulanus*. The band near the distal margin is likewise dull and washed-out, only in the anterior part somewhat more distinct, never yellowish in tone, but pale grey-brown like the distal margin. Hindwing with stronger whitish dusting at the distal margin, the blue of the basal area not extending to the end of the cell. Under surface almost as in the preceding, the cell of the forewing somewhat more regularly watered, on its projecting angle less brown clouding and the light patch more weakly marked. Hindwing with the ground-colour white, the striation coarse, especially in the basal area. The posterior eye-spot very strongly marked, its ring very broad, light ochre-yellow, at the outer edge shaded with orange; the brown foreground less extended, light sepia, the transverse stripe running to the anterior eye-spot not always fully developed. ♀: band-markings on the forewing more distinct, almost as in *C. eurilochus brasiliensis*, but not so sharply defined, the blue tinge on the forewing less extended and duller, the costal margin in particular more broadly grey. The characters not quite constant, varying individually. Size of the preceding. — *morpheus* Stich. inhabits Central Colombia; it is of very dusky, uniform, dark blue-grey colouring with the submarginal band only quite weakly indicated. Under surface coarsely and regularly watered, the large posterior ocellus only brown anteriorly. According to STICHEL *morpheus* extends southwards to Ecuador and Peru, where it unites with *livius* Stgr. — *phryasus* Fruhst. Very small in habitus, about agreeing with *sulanus* Fruhst. from Honduras, also similar to this race above in coloration, but easy to distinguish by the lighter blue, more inclining to grey, on the forewing, which, moreover, bears a short whitish band at the wall of the cell. Hindwing extremely characteristic by having the black distal area widened and encroaching on the cell. In the middle of the wing an intensively glossy dark blue reflection, which decreases towards the base. Under surface similar to *sulanus*, ocellus of the hindwing larger, more distinctly bordered with lighter yellow, placed in a deeper brown foreground. Maracas Fall, Trinidad. Collected by A. H. FASSL. — *livius* Stgr. Usually larger than the typical form; forewing pale grey-brown, even paler than in the typical subspecies, distal area somewhat darker, particularly in the posterior part, there brownish or pale blackish and divided for its entire breadth from the rest of the wing by a vague yellowish transverse band, which anteriorly is mostly somewhat more distinctly expressed. The spots near the apex indistinct and washed out, distal margin somewhat lighter, before it some vague nebulous shading, enclosed by or adjoining the marginal lines which show through from beneath. The blue tinge in the posterior part of the wing is very faint, the green reflection at the costal mar-

gin and in the cell entirely absent. Hindwing with whitish fringes. The blue basal area leaves the anterior part of the cell free, is posteriorly extended only to one-half the submedian and shows only a slight sky-blue gloss. Under surface somewhat more uniformly and regularly striated, the pupil of the eye-spot at the anal angle commonly somewhat reduced, so that the eye-spot is very broadly ringed with yellowish. ♀: forewing almost smoke-brown, with very slight blue tinge. The spots near the apex more distinct, blackish, dotted with white internally; distal area somewhat darkened; near the distal margin runs a lighter transverse band of spots, strongly curved posteriorly. Between this and the margin itself, which is again somewhat lighter, is placed a smoke-brown stripe, distally straight, proximally strongly curved. There is no real transverse band behind the cell, only its commencement being indicated at the costal margin by a yellowish diffuse spot. Hindwing with the basal area quite faintly blue; the bluish tinge, however, extends to beyond the end of the cell and nearly to the hinder angle; before the posterior half of the cell, extending somewhat beyond its end, and in the median area of the wing some sparse ochre-yellowish dusting is sometimes perceptible. Distal area black, the margin slightly dusted with yellowish white. Under surface of the hindwing near the distal margin with two somewhat more distinct undulate bands. Markings on the underside of the forewing showing through above almost throughout. Western Amazons, Peru. According to Dr. HAHNEL *livius* is very shy of the light and remains hidden during the day in dark, shady places, possibly where rotting fruits have attracted it during its flight in the twilight. When disturbed their flight is jerky, the wings only flapping a little, and occasionally they settle in the dark, but nevertheless visible from far off, on a hanging liana. The whole under surface of the butterfly is then exposed, with the large brilliant yellow eye-spot showing up strikingly on the variegated grey hindwing, and giving the insect almost an aggressive appearance. The colouring is, however, thoroughly adapted to the grey of the twilight for the short half hour during which *livius* makes its appearance morning and evening. — **caesia** *Stich.* was described from Venezuela. Forewing suffused with light blue except for the rather intensively black distal-marginal part. Under surface densely striated. Round the large ocellus of the hindwing a deep dark brown patch. Strigulation in general finer than in *brasiliensis* *Fldr.* — **eurilochus** *Cr.*, the typical subspecies, is rather rare. Upper surface of the wings pale grey, the striation of the under surface showing through, sometimes with slightly brownish tone, distal area somewhat darker, anteriorly but little, posteriorly more distinctly differentiated from the rest of the wing, more rarely slightly blackish (rainy-season form ?), then at the boundary a lighter, washed-out, narrow transverse band, which touches the posterior angle of the cell, is anteriorly slightly tinged with yellowish and terminates vaguely at the middle median vein. In more uniformly coloured examples only a small, pale yellowish diffuse spot remains at the costal margin before the fork of the fourth and fifth subcostal veins. The small spots near the apex mostly only indistinct, without or with only very little white bordering. Surinam, Guiana. — **brasiliensis** *Fldr.* often attains a huge size, but from Espiritu Santo to its southern limit (Sta. Catharina) it does not seem to vary, that is to say, to be separable locally. *brasiliensis* may be known at once by the prominent pure white subapical spots on the upperside of the forewing, which are not developed to the same extent in any other subspecies. Yet examples occur, particularly in Blumenau and Espiritu Santo, in which these spots are either entirely absent or only indicated. Blumenau ♂♂ have more copious white irroration in the distal area of the hindwing beneath, perhaps indicating an incipient race. At the same time a ♂ from Espiritu Santo is the melanotic extreme. This lacks not only all the whitish, but also the yellow-brown striation, in place of which a mealy powdering of the finest blackish scales is present (= **privata** *form. nov.*). In the submarginal area of both wings there is a well developed longitudinal band of black colour and as the ocelli are also reduced and darkened one is tempted to think one has a separate species before one. Egg hemispherical, in the middle with an elevation somewhat like a girdle, beneath lighter and transversely grooved, attached to the underside of leaves. Larva cylindrical, tapering anteriorly and posteriorly. Head angled, sloping anteriorly, dirty white with black lines, when young with dense bristles, afterwards with 8 horns forming a short of crest. Body at first dirty white, later green with dark, anteriorly forked mediodorsal band containing red-brown spots; when full-grown the larva is dirty grey-yellow with darker-spotted dorsal line and irregular black lateral oblique stripes sloping down posteriorly. At the posterior margin of the 5th—8th segments are placed short, soft, conical protuberances up to .4 mm. in height (false thorns); the tail is prolonged into a fork of about 9 mm. in length. Body up to 12 cm. long. As long as the larva is green (to the third moult) it rests on the underside of the banana leaves (according to SOMMERFELD gregariously), afterwards it hides on the stem among dry, hanging leaves, feeding chiefly at night. Pupa robust, broad, tapering posteriorly and anteriorly. Dorsal edge strongly projecting, wing-margins likewise strong, 6th—10th segments with short black bristles on the dorsum. Body brown-red, with black dots, black dorsal and lower lateral stripes and black lateral oblique bands, sloping down posteriorly. On the wing-case two silvery, brownish-margined spots, the abdomen only with one entirely free (movable) segment. The metamorphosis occupies 3—4 weeks. Brazil (Amazons and southwards), Argentina. — **pallidus** *Fruhst.* Bolivia produces a strongly differentiated *eurilochus* race, for which I propose the name *pallidus*. It has more rounded wings than *eurilochus* and *livius* and the forewing is completely transparent, particularly towards the apex. The scaling in the cell is not blue but yellowish and the whole apical part of the forewing appears light brown, as the colour of the under surface shows through intensively above. The black marginal border is almost entirely suppressed, only remaining perceptible in the anal angle of the forewing, behind the 3rd median vein. The hindwing on the contrary is more broadly margined with black-brown

and the brown colour extends even beyond the apex of the cell. The basal half of the hindwing is lighter, blue-grey. The under surface is at once distinguishable from *eurilochus* and *livius* by the yellowish brown instead of grey-white colouring. The anal angle of the forewing is not whitish but dark grey. The subapical ocellus of the forewing is much reduced and all the ocelli of the hindwing are also considerably smaller and more narrowly ringed with black outside. The large ocellus of the hindwing is not rounded but flat oval and more like a cat's than an owl's eye. Bolivia.

C. idomeneus is one of the most beautiful species of the genus, in habitus scarcely inferior to *eurilochus*, though it has narrower wings. It is even more susceptible to geographical influences than *eurilochus*, and splits up into a series of local races, mostly sharply differentiated, of which only three extend beyond central Brazil. Upper surface similar to *philinos*, but the forewing more pointed, with the submarginal band differing in the different races, sometimes pure white and strongly expressed, sometimes again darkened or absent. Under surface always with prominent white patches in the cell, particularly in the ♂♂ and a brilliant patch of white striation in the submarginal area of both wings. Hindwing always with round ocelli, margined with bright yellow and placed in a brown or yellow foreground. **idomeneus** L., the name-type, inhabits Surinam, where my collector JULIUS MICHAELIS captured large numbers by means of banana-bait. All the examples before me bear a sharply defined white longitudinal band, terminating at the posterior median, on the forewing, which in the ♀ is considerably more weakly developed and is already lost at the middle median. ♀ beneath always more deeply coloured, more uniform than the ♂, also in the distal area of the hindwing predominantly striated with brown-yellow. — **apollonidas** *subsp. nov.* is only known to me at present in 2 ♂♂ from Obidas on the Middle Amazon, where MICHAELIS found it in August and September. ♂ easy to distinguish from *idomeneus* from Surinam by the purer white submarginal band of the forewing, which is not sharply defined but extending into the apex of the cell and there gradually lost. The black submarginal area of the hindwing narrower than in the name-type, hence the cell in particular more broadly tinged distally with ultramarine blue. Under surface of the hindwing without a definite brown anteterminal area, eye-spots larger, bordered with paler yellow. — **euphorbus** Fldr. was lost for a long time, but was rediscovered by Dr. KOCH-GRÜNBERG and I have recently obtained examples also from the probable original locality, the Colombian part of the upper Rio Negro. *euphorbus* is a poorly coloured, dusky local form with the band of the forewing washed out and the blue on the upper surface deeper and almost without gloss. Under surface very variable according to the locality. One ♀ is predominantly dull smoke-brown, with only a slightly lighter transcellular patch on the hindwing. The ♀ from Colombia (upper Rio Negro) on the contrary is distinguished by a broad, band-like, nearly white median area and still more by the submarginal pointed marks, which are proximally white but otherwise filled in with light brown. The Colombian ♂ also is much darkened above, the longitudinal band of the forewing costally yellowish, otherwise grey, and as narrow as in *idomenides* Fruhst. For the latter local race I would propose the name **stratonides** *subsp. nov.* — **marsus** Stich. is a subordinate form, deeper-coloured and more strongly shot with blue, about as in the form *euphorbus*. Whitish band on the forewing narrowed; costal and basal areas of the forewing with greenish gloss when viewed from in front. Ground-colour to the end of the cell and the blackish marginal area blue-violet, slightly tinged with greenish. Hindwing to the end of the cell with faint blue-green gloss, thence deep sky-blue; the distal margin, however, remains quite narrowly black and is slightly dusted with whitish particularly behind the apex. The deep blue reflection extends anteriorly almost to the costal margin, only proximally leaving a blackish grey silky area. Hindmarginal area dirty yellow. Under surface with the characteristic glaring ochre-yellow colour in the posterior area, communicating itself to the bordering of the posterior eye-spot, so that the ring of the eye-spot is lost in the yellow area. The ground-colour behind the cell chiefly white and only very sparingly striated. **idomenides** Pará; also in other localities together with the type-form. — **idomenides** Fruhst. Similar to the preceding form, wings somewhat narrower, some of the examples smaller, ground-colour sometimes paler. Band of the forewing in the ♂ narrowed, only visible in whitish colouring to close to the upper median vein. The blue basal area of the hindwing reduced, in an oblique light always greenish, a narrow stripe with a deep blue gloss bounding it distally; the reflection only reaches to half the cell and is also posteriorly broadly separated from the blue colouring of the distal margin or sometimes diffused along the posterior median vein as a deep blue tone to the hinder angle. Distal margin slightly dusted with whitish; ♀ scarcely differing above except in the reduction of the blue basal area on the hindwing; it extends here only about to the end of the cell, the whitish band of the forewing terminates indefinitely at the anterior median vein. Peru. — **hippolochus** *subsp. nov.* The whitish longitudinal band of the forewing somewhat narrower, sharper than in *idomenides* from Peru; under surface lighter, all the whitish parts broader, submarginal area of the hindwing nearly pure white, almost without striation, the submarginal band of red-brown pointed curves which in *idomenides* extends distinctly almost to the terminal border absent. Ocelli ringed with lighter yellow and then more broadly with black. **superba** Coroico, 1200 m., Bolivia. — **superba** Stgr. Apex of the forewing rather sharp, somewhat produced. Ground-colour suffused with blackish, transverse band pure white, sharply defined, anteriorly slightly curved, posteriorly ending in a point beyond the posterior median vein. Hindwing to the end of the cell with blue-grey basal area, which in an oblique light shows a greenish, at the distal edge a deep blue gloss; from here onwards to the distal margin a sky-blue reflection is visible in an oblique light, only leaving a more or less large

spot at the apex. Distal margin of the hindwing strongly dentate, slightly and narrowly dusted with whitish. Under surface marked and coloured as in typical *idomeneus* but more sharply; the posterior eye-spot of the hindwing comparatively small and narrowly ringed, the white area behind the cell rather strikingly contrasted with the about equally broad brownish distal area. Southern Peru. — **praecana** *Stich.* is a form of the preceding. Shape about as in typical *idomeneus* or *agamemnon* with the distal margin of both wings strongly undulate, wings less broad, as large as *superba*. Above clearer grey, even paler, than typical *idomenides*, markings of the under surface showing through distinctly. Band of the forewing narrow, about as in *idomeneus*, the blue reflection extended, but scarcely more than in *idomeneus* itself and on the hindwing not very brilliant. Distal part of the hindwing black-brown. Under surface about as in *idomeneus*, but all the dark parts lighter brown. Ground-colour reddish ochre, the double line before the distal margin of the forewing more strongly dentate. On the hindwing the light areas before and behind the brown median band lighter, hindmargin as far as the submedian ochre-yellow, which colour is extended in the anal area and united with the bordering of the posterior ocellus. The under surface recalls *rhoetus*, but is even lighter and more yellow. South Peru. — **agamemnon** *Weym.* is the largest race. Apex of the forewing almost falcate, distal margin below it deeply excised, undulate. Ground-colour dark, nearly black, but the markings of the under surface showing through faintly, particularly in the cell and at the distal margin. Band of the forewing widened, pure white for its entire breadth as far as the posterior median vein, beyond this distally whitish nearly to the submedian, proximally dusted with bluish. Transverse band anteriorly somewhat narrower, somewhat dentate, the sections between the veins arranged as a series of crescentic or arcuate spots. Posteriorly these arcuate spots become shallower, the band more continuous and only finely intersected with blackish at the veins. Not far from the costal margin, near the apex, there is a small white spot and sometimes a second following it. Hindwing somewhat elongated, at the distal margin extremely dentate, projecting almost in points at the extremities of the veins. Basal area grey-blue to near the end of the cell, in an oblique light greenish, distally with blue reflection. Distal margin itself slightly dusted with whitish. Under surface extremely light, but marked in the same way as in *idomeneus*. The transverse band of the forewing, however, much broader, the dark shading which continues the brown colouring in the median area behind the posterior median vein condensed into a more distinct band, the lines near the distal margin more strongly dentate, the proximal bordered with whitish and towards the adjacent brownish area shaded with black-brown, so that it loses the effect of a separate line and forms a sinuous boundary to the adjacent part of the wing. Hindwing traversed by a complete brown median band; the posterior eye-spot, however, the greater part of which is enclosed in the band, smaller than in typical *idomeneus*. The area behind the cell very distinctly separated from the distal area proper by the white-edged, strongly dentate, band-like marking halfway between the end of the cell and the margin; ground-colour of the distal area anteriorly chestnut-brown, posteriorly only brown along the veins, otherwise whitish. The white patch in the middle of the cell sharply defined. Ecuador (Huamboya, Balzapamba). — **rhoetus** *Stgr.* In the ♂ the white band of the forewing is narrower and shorter, at most only distinct to the 2nd median vein; the blue reflection on the hindwing interrupted in the median area. Anal area ochre-yellow, beneath the entire posterior part of the wing as far as the posterior ocellus bright ochre- or saffron-yellow; the under surface is more brightly marked than in typical *idomeneus*, particularly the whitish cell-patch mostly sharp and the transverse bands in the cell of the forewing purer whitish and sharper. ♀ the same but paler. Eastern Amazon and part of Brazil lying to the south of this; Argentina (?). I have *rhoetus* before me also from Matto Grosso, a single ♂ differing inconsiderably from STAUDINGER's type, which I had the opportunity of seeing in the museum at Berlin a year ago. — Two further adjacent geographical races may be separated: namely **ibykus** *Fruhst.*, which agrees with the Matto Grosso form in its relatively small size and the scarcely produced apex of the forewing. In *ibykus*, however, the anal and basal part of the hindwing beneath a duller, deader shade of yellow. White band of the forewing resembling that of *idomeneus* from Surinam. Minas Geraes; described from 2 ♂♂ and 1 ♀ in coll. FRUHSTORFER. — **ariphron** *Fruhst.* The white band of the forewing much resembles that of *euphorbus*, but stands out somewhat more distinctly in the ♂ and is much reduced in the ♀ but still always somewhat less darkened than in the ♀ of *euphorbus*. Forewing of the ♂♂ with the apical part much produced, the longitudinal band, compared with *ibykus*, scarcely half as broad in spite of its larger size. Under surface, in accordance with its more southerly habitat, with the yellow basal tinge on the hindwing almost entirely suppressed and the forewing essentially darkened. Espiritu Santo, from 2 ♂♂ and 3 ♀♀ in my collection.

C. menoetius *Stgr.* is a rare, very interesting species, nearly allied to *idomeneus*, which has led the monographer of the Brassolids to confuse it with the latter and erroneously to call it *euphorbus* *Fldr.* There is an excellent figure by STOLL in the fourth part of CRAMER's celebrated work as long ago as 1782, on pl. 390. STOLL, however, originated the mistake, as he represents a ♂, but calls it *idomeneus* ♀. STAUDINGER has quite correctly observed and pointed out that *menoetius* differs from other *Caligo* in the strikingly narrow hindwing. Upper surface uniform dark ultramarine, in the ♂ without a trace of a band, only with broad, pale submarginal area showing through faintly from the under surface. The still undescribed ♀, of which there are four examples in my collection, is round-winged, larger than the ♂, lighter blue with brownish white submarginal area on the forewing. Both sexes with the black distal margin of the hindwing scarcely half as broad as in *idomeneus*. Under surface recognizable by the more vividly contrasted colours: thus both wings are traversed by a more compact dark brown median area, in which are placed the somewhat larger and more

distinctly black-ringed ocelli. Forewing with very broad black intramedian spot beyond the cell-wall and essentially more pronounced black zigzag stripes in the cell itself. Both wings then bordered distally with deeper brown and blackish. If it is further added that the median area of the hindwing stands out more sharply whitish than in *idomeneus*, all those differential characters have been mentioned which STOLL's figure reproduces so unmistakably. Surinam, also found by Dr. HAHNEL at Maues on the Lower Amazon. — *aristophanes* *subsp. nov.* is smaller than *menoetius* from Surinam and the upper surface may be at once known by a rather broad yellowish longitudinal band, suggesting *idomeneus*, which extends as far as the middle median. This band, however, is always weaker than in *euphorbus* and *stratonides*. But where *aristophanes* surpasses *menoetius* is in the still more glossy, purer, brilliantly iridescent blue of the hindwing. Under surface easy to distinguish by the lighter grey-brown submarginal areas on the forewing and by a row of brown pointed curves which are wanting in *menoetius*. Coroico, 1200 m., Bolivia. Only known to me in one ♂ in coll. FASSL.

C. atreus is perhaps the largest species of the genus and at the same time the most gaily coloured. Forewing black with a blue-violet median area, which is traversed by a whitish stripe varying in distinctness according to the local race. Hindwing with broad light yellow or orange band, again of greater or less breadth and with the margins more or less incised in the different local forms. Under surface brilliant red-brown with yellow or orange distal area. Apical ocellus of the hindwing very large. Five well separated geographical races: *atreus* *Koll.* In the ♂ the blue-violet dusting of the hindwing viewed from above weak, in an oblique light somewhat more distinct; in it an oblique light band, anteriorly only indicated by thin, short whitish yellow hairs and scattered light scales, gradually becoming more distinct posteriorly and about from the lower angle of the cell onwards grey-white slightly dusted with bluish, changing towards the anal angle into almost pure white. Boundary of this band not sharp, dusted with grey and bluish, and gradually shading into the adjoining ground-colour. Distal area light smoke-brown. In this is sometimes placed a nebulous, slightly undulate, dark stripe, separating another, lighter, band-like stripe from the distal margin; the latter stripe again is proximally bounded by the corresponding, more sharply dentate second marginal line of the under surface. Sometimes the dark stripe is absent or very much weakened. Band of the hindwing light ochre- to saffron-yellow, anteriorly whitish, proximally not sharply defined and on the veins and between them subdentate. The band terminates about at the extremity of the posterior median vein or somewhat before it. ♀ with broader wings, the median area of the forewing suffused with lighter blue, the transverse band mostly somewhat more distinct, the marginal band of the hindwing broader, pale ochre-yellow, anteriorly more strongly whitish. Under surface lighter, the markings somewhat weaker. Colombia. — *dionysos subsp. nov.* differs from *atreus* in having the band of the forewing continued to the costal margin and almost uniformly whitish, dusted with blue-violet, in which this form approaches its next representative, *ajax*. On the hindwing the orange distal area remains darker, reaches the black distal border and becomes broader (transition to *C. uranus*). Under surface with more pronounced contrasts in colour, the white stripe of the forewing more sharply defined and especially proximally straighter, apical ocellus of the forewing larger, anal ocellus of the hindwing considerably smaller, median area of the hindwing deeper brown, conspicuously margined with black distally. Chiriqui (coll. FRUHSTORFER). — *uranus* *H.-Schäff.* is the northern representative of *atreus* and strictly speaking only a geographical race of this widely distributed species. It seems, however, not inconceivable that it might form a separate species on account of its small size, more rounded wings, the absence of the black distal border of the hindwing and the presence of larger white subapical patches on the forewing. The under surface on the contrary can only be distinguished from *atreus* by the smaller eye-spots on the hindwing. I have examples before me from Honduras, where *uranus* occurs very rarely; to the north southern Mexico forms the limit of its range and according to GODMAN it is not very rare in Guatemala, where it inhabits the dense woods; when startled up it flies a short distance and then hides on the tree-trunks. — *ajax Westw.* has the band of the forewing broader and more distinct; at its commencement at the costal margin this is whitish grey with bluish dusting, but gradually changes to a pure white colour. In the middle median cellule the band is as a rule only slightly dusted with blue, the blue scales are there placed at both sides on the edges and finally disappear entirely. Band of the hindwing darker saffron-yellow, in an oblique light with a quite faint purple-red or violet hue, posteriorly strongly bent in a point towards the hinder angle. Venezuela. — *dentina* *Druce* has the band of the hindwing almost continuous for its entire length, only anteriorly broken up into spots, at the proximal edge deeply dentate. Peru, Ecuador (Chimbo, Balzapamba), Colombia (Rio San Juan). — *agesilaus* *Druce* has the forewing as in *dentina*, but the light transverse band somewhat more distinct. In the distal marginal area the blackish nebulous stripe likewise more distinct, so that the proximally adjoining light part near the margin is defined as a dentate band. Band of the hindwing broken up into five separate spots, which are rather remote from the distal margin and of which the posterior ones, and occasionally also the anterior, are loosely connected by a slight dusting. Their colour is yellowish white, the posterior ones somewhat darker. The blackish marginal dusting extends to the middle median vein and is united at the veins with the black-brown ground-colour of the rest of the wings. The anterior marginal spots are heart-shaped, being proximally incised in the middle, the posterior ones elongate. Fringes whitish yellow, standing out conspicuously against the marginal dusting. Under surface as in *dentina*, except that the posterior eye-spot of the hindwing is comparatively very large, the distal area for its entire length mar-

pled and striated with whitish and blackish, and only a narrow stripe near the distal margin, corresponding in position to the row of spots on the upperside, is more uniform whitish. The cell-patch and the elongate ring-spot before the middle discocellular are distinct. ♀ like the ♂, but in general paler. Perhaps only a seasonal form, as transitions occur to the preceding subspecies. Ecuador, Colombia (Valley of the Rio Dagua).

C. arisbe *Hbn.* (65 a), so far as is known, inhabits only the three Brazilian states of São Paulo, Rio de Janeiro and Espiritu Santo. I have no examples from the two former, but in Espiritu Santo *MICHAELIS* has baited and captured *arisbe* sparingly with bananas. The larva lives on Marantaceae. Under surface predominantly yellow-brown with the median area much lighter yellowish, particularly in the ♀. Anal ocelli strikingly broad, first yellowish, then olive-coloured, finally ringed with black, connected with one another by an extended, distinctly defined brown area.

C. oberthueri *Deyr.* is near to *arisbe* and must be regarded as one of the most beautiful *Caligos*. Upper surface of the forewing dark brown-grey, that of the hindwing brown-black, the latter except at the distal border with violet-blue reflections. Under surface dark black-brown with a conspicuous pure white longitudinal band. Ocelli on the underside unusually small. Colombia, Ecuador, very rare. — **phokilides** *subsp. nov.* inhabits Peru (Chanchamayo) and differs from Colombian examples in having a more indistinct, lighter yellowish longitudinal stripe on the forewing. ♀ lighter, the markings in the distal area more distinct. It bears there a partially blurred undulate line, followed proximally, near the margin of the wing, by a sinuous and dentate band. In the anterior part of this are placed near the apex three blackish spots, proximally edged with whitish, one behind another, accompanied posteriorly by two further more shadowy spots. The band behind the cell is more distinctly defined, almost ochre-yellow, anteriorly widened and shading into the ground-colour without any sharp demarcation. Hindwing with less of the blue gloss, faintly shot with violet, the light transverse band-like patch paler and broader, in particular anteriorly; the distal margin more broadly dusted with ochreous. Under surface as in the ♂, but lighter. The egg of this rare species is only half the size of that of *epimetheus* and even smaller than that of *Opsiphanes bogotanus*. It is of a wax-yellow colour with longitudinal ribs, base and apex somewhat flattened and smooth. Larva much darker than that of the preceding species, nearly black; the dorsal markings consist of several irregular light brown spots; the dorsal (false) thorns are black and bent somewhat forwards. Crest on the head and tail-fork much shorter than in *epimetheus*. The food-plant is a low species of palm with primitive, nonfeathery leaves. The larvae seem mostly to occur in pairs. FASSL observed *oberthueri* only on the crest of the West Cordillera above 2000 m., whilst *epimetheus*, although also a mountain butterfly, only occurs lower (from 1400 to 1800 m.); this also fully corresponds with the localities of the food-plants of the two species.

C. martia *Godt.* (65 b) occurs where *arisbe* disappears and has hitherto only been brought to Europe from Santa Catharina and Rio Grande do Sul. Probably, however, the species also occurs in the state of Paraná, which unfortunately has only been insufficiently explored. An example in my collection, which I received from Herr JULIUS ARP as coming from Rio de Janeiro, shows somewhat smaller anal ocelli on the underside of the hindwing, but the locality is not quite certain, especially as Herr ARP has obtained much material from Santa Catharina. *martia* is the rarest south Brazilian *Caligo*; it always only occurs singly and extremely seldom comes to baits of fruit. But it is found with great regularity on the highland of Lages near the sources of the Uruguay at bleeding trees, where the butterflies feed greedily, but are nevertheless very shy, so that it is not easy to take them off their guard. The larva was apparently first described by MABILDE. It is green with yellowish lateral stripes. Head with two short protuberances and two long setiferous horns, dorsum with five false thorns, hairs small, quite fine, tail with the customary double point. Pupa dark havanna-brown. Head slightly pointed, abdomen elongated, middle part thickened, and with four transverse stripes. From September to October. Pupal stage 20—25 days. ♂ smaller than the ♀, which we figure, and wanting the transparent submarginal band of the forewing, under surface with a nebulous, black-bordered spot in the cell of the forewing, which no other *Caligo* species possesses to the same extent. Behind the cell three unequal white intramedian patches. Apical ocellus of the forewing relatively large. Anal ocellus of the hindwing much as in *arisbe*, black with broad yellow bordering which posteriorly shades into greenish. In the cell of the hindwing an elongate irregular spot, which is very variable, hardly alike in two examples, in the somewhat lighter ♂♂ and ♀♀ from Rio Grande do Sul better developed than in Santa Catharina examples.

8. Genus: **Narope** *Westw.*

In this the smallest Brassolid genus we have at the same time reached also the most considerable deviation from the type in shape and neurulation, and indeed the species more resemble an *Anaea* than a Brassolid in their smaller size, the sharply pointed forewing, the short teeth at the medians in the hindwing, and in having the upper surface mostly uniform brown and the under surface entirely without eye-spots and variously irrorated; yet all other points of structure, such as palpi, forelegs and the large precostal cell, agree completely with the family characters, while the discovery of the larva by Dr. W. MÜLLER has removed all doubt as to the

position of *Naroepe*. The genus differs at once from all the others in the 3rd subcostal vein running into the apex and the fork of the 4th and 5th into the distal margin below the apex. This striking neuration occurs extremely rarely even among the Satyrids and is more a character of the Nymphalids. In addition *Naroepe* is distinguished by further characters. The subcostal vein is not constant in the separate species, but both 4- and 5-branched; the 1st branch is either entirely wanting or in part coincident with the costal. The upper discocellular is short, but distinctly present; the middle straight, in the same direction and of the same length as the lower, which is only weakly curved, closes the cell obliquely and meets the median vein at a somewhat greater distance from the 2nd branch than this is removed from the 1st. The submedian of the forewing is strongly sinuous in the ♂, this formation being closely associated with the presence of a tuft in the ♂ (as sexual character) on the under surface beneath this vein; with the hair-tuft corresponds a shiny spot at the costal margin on the upperside of the hindwing. The precostal cell is extraordinarily large and well developed; the precostal vein simple, nearly straight, proximally directed. The cell is obliquely closed by a rather short and straight lower discocellular. Head large, eyes naked, palpus flat, densely scaled and haired; first joint short, second about 4 times as long, terminal joint short, pointed, extending beyond the head. Antenna moderately long with the club gradually thickened. Thorax strong, densely haired; legs strong, abdomen short, pointed. Forewing with strongly curved costa and prominent, pointed apex. Distal and inner margins in the ♂ nearly straight, anal angle sharp. The under surface mostly bears a scent-spot and hair-pencil. Uncus with the processes short and divergent, i. e. with the points directed outwards. Valve simple, with two strong teeth. Hindwing often slightly angled. Cell of the forewing broad at the end, more than half the length of the wing. This genus contains the smallest species of the family; they are uniformly coloured, the under surface resembling leaves; they come to light and are also observed on bait at night. — Larva on bamboo, feeding by night, its general appearance like that of the other Brassolid larvae. Head with 3 pairs of horns, end of the body with tail-fork. — Pupa compact, ventrally compressed, with short tubercles and two horns on the head, suspended, with one free segment. South and Central America (from Paraguay to Guiana on one side, from Bolivia to Mexico on the other).

Hindwing more or less distinctly produced at the distal margin.

testacea. **N. cyllastros** is the commonest and best known species of the genus and is at the same time the only one which extends northwards beyond Colombia and of which the early stages are known. — In *testacea* Godm. & Salv. the ♂ is rust-red above, apex of the forewing and basal half of the hindwing darkened with brownish. Distal margin of the latter wing only feebly angled at the middle median vein. Under surface pale ochreous with scattered darker small spots, striae and shading, the whitish spots of the hindwing apparently always absent with the exception of the anterior ones. ♀ with the hindwing more strongly angled; upper surface of the wings dark brown or smoke-brown. Panama (Chiriqui). Very rare, only a few examples yet found. — *stygius* Stgr., from Fonteboa on the Upper Amazon, was erected on a ♀ received from Dr. HAHNEL. Smaller, with the general colouring even darker than in *cyllastros* (62 d), under surface somewhat less intermixed with whitish grey. Hindwing with seven yellowish anteterminal dots, of which the first is distinctly oval and ringed with black, whilst the sixth is the strongest. — *cyllastros* Westw. (= *cyllene* Fldr.), probably described from examples from Rio de Janeiro, is considerably darker in the ♂ above than the original of our figure (62 d) (which came from Santa Catharina) and beneath as pale as the ♀ figured from Santa Catharina; a difference which is already mentioned by STAUDINGER in his „Exotische Tagfalter“ 1888, p. 218. In the course of two years I took only a few examples near Theresopolis, Sta. Catharina, and I have ♀♀ before me from Blumenau. According to BÖNNINGHAUSEN very rare in shady places near Rio de Janeiro. Taken by me at banana bait. Dr. WILHELM MÜLLER found the larva feeding at night on bamboo, it was already in the fifth stage and a few days before pupation was 7.5 cm. in length, inclusive of the tail-fork, which was 6 mm. Head with three pairs of horns obliquely directed posteriorly, arranged like a collar, body thickened towards the middle, otherwise slender, the horns and the tail-fork laterally compressed, the two parts of the tail arising far apart, but running parallel; head brown with a black spot in the middle below the horns, which sends out two stripes to the base of the horns and two to the lower angles of the head. Body a mixture of pale red and grey-brown. The pale red colour is somewhat irregularly arranged and forms undulate lines. Pupa rather stout, the posterior segments dorsally rounded with a slight central ridge, which is divided into three humps, in addition two further protuberances at the base of the wings and two horns. The wing-margins are indistinct. The markings present a peculiar mixture of yellow, brown and black; here and there, especially on the dorsum, there are some white spots.

cyllarus. **N. cyllarus** Westw. (62 d) with the type from the state of Rio de Janeiro, where the species occurs very rarely in the Organ Mountains. MICHAELIS discovered it in Espiritu Santo, I myself found it in Santa Catharina. One ♂ in my collection is said to come from Rio Grande do Sul and STICHEL names São Paulo as a further locality. ♂: head and eyes uniformly reddish brown. Venter and legs pale ochre-yellow. Upper surface reddish brown, of lighter or darker tone, basal and apical areas somewhat duller. At the end of the cell, on the lower disco-

cellular and again not far from the distal margin between the radials there is a small black-brown spot, the last-named sometimes indistinct or absent. Distal margin darkened, with a narrow blackish undulate band, not sharply defined. Under surface pale ochre-yellow, very variegated, irregularly marbled with darker and whitish shades. At the costal margin, in the cell and in the distal marginal area dotted with dark brown, then with two more or less distinct dark transverse bands; apex dusted with whitish, at the turned-up part of the hindmargin an anteriorly directed light hair-tuft, covering an anal scent-spot. Hindwing with the distal margin angled at the second median vein; colouring as in the forewing, at the end of the cell darker spotted, anal area lighter, a scent-spot at the middle of the costa. Under surface lighter with dark transverse band; distal area darker with submarginal undulate band. In the ♀ the distal marginal band is more sharply defined, general colouring somewhat paler. South Brazil (Sta. Catharina, São Paulo, Espiritu Santo).

N. sarastro *Stgr.* Head dull ochre-yellow, upperside of the abdomen and thorax red-brown, underside *sarastro*. and legs ochre-yellow. Forewing with scent-spot and pencil as in the preceding species; shape of the wings similar, but the apex of the forewing more pointed, more projecting. Upper surface red-brown, apex and distal margin blackish. Under surface almost ochre-brown, with darker spots and striation, especially at the costa. Cell crossed by two diffuse, darker bands. A triangular darker marginal area in the distal third of the wing is bounded by a light stripe, running from the apex towards the middle of the inner margin. Hindwing unicolorous with very dull submarginal band which is darker at the apex. Under surface with 3 diffuse, darker parallel bands, running from the costal margin in a slight curve to the inner margin. ♀ dark brown, distal margin narrowly reddish brown, apex of the forewing strongly produced; starting from the costal margin an elongate diffuse reddish brown spot, which is bag-shaped and rounded off near the distal margin below the apex. Under surface light grey-brown, irregularly irrorated and dotted. In the apical area dusted with whitish, from there obliquely towards the hindmargin a darker, distally dirty white nebulous band, much as in the ♂. In the fork of the 4th and 5th subcostal veins and also below the latter a small whitish spot, behind it a small blackish spot, slightly white-pupilled, then again a small white dot. Hindwing with the distal margin lighter, not sharply defined. This shade is widened posteriorly and anteriorly runs out on the veins. Under surface coloured like the forewing, indistinctly clouded with darker, near the middle of the costal margin a dark dot surrounded by a lighter area, accompanied posteriorly by a row of spots parallel with the distal margin, the first two are mere rounded spots of a lighter shade, while those which follow form elongate whitish patches. Colombia, Rio Agnaca Valley, about 2000 m., Upper Rio Negro at about 800 m., taken by FASSL. — **disyllus** *subsp. nov.* *disyllus*. is a smaller form, mainly grey-brown instead of reddish ochreous, the apical border of the forewing duller grey instead of black, the terminal band of the hindwing washed out, the yellowish patch in the cell and along the costal of the forewing in more vivid contrast to the grey median part. Under surface darker, more copiously banded with red-brown and with deeper purple gloss. Huancabamba, 1500 m., Peru.

N. anartes *Hew.* Forewing in the ♂ forming a right-angled triangle, costal margin curved, apex *anartes*. rectangular, sometimes produced into a slight point, distal margin nearly straight. Hindmargin straight, from the base outwards somewhat folded over for a third of its length. Upper surface lighter or darker rust-brown. Apex broadly blackish. Under surface pale ochre-yellow, with the exception of the hindmarginal area spotted and clouded with black-brown. Across the cell run 2 dark, irregularly defined bands. Before the apex close to the costal margin a small white spot, the apex itself dusted with whitish. At the folded part of the hindmargin a light brown hair-tuft, covering an oval yellow scent-spot. Hindwing smoke-brown, distal margin with undulate boundary-line, relieved with rust-brown. Under surface brown, clouded, spotted and watered with lighter and darker; a dark band from the middle of the costa obliquely across the cell to the submedian. Median area sometimes posteriorly dark shaded and bordered with whitish, and containing an undulated row of spots parallel with the distal margin. The spot in the lower median cellule always somewhat larger and more distinct, mostly elongate or reniform. Close to the uniformly brown distal margin is placed a blackish undulate line, the margin itself is more or less undulate and at the middle median vein more or less strongly angled. The colouring, particularly beneath, of varying sharpness, the under surface sometimes with very diversified marbling. Bolivia. — **syllabus** *Stgr.* is the somewhat larger race from Chanchamayo in *syllabus*. Peru.

Distal margin of the hindwing in the ♂ fully rounded.

N. nesope *Hew.* Forewing triangular, apex sharply rectangular, distal margin anteriorly straight, *nesope*. posteriorly slightly convex; hinder angle smoothly rounded, hindmargin straight, near the middle narrowly turned up. Upper surface red-brown, basal area behind the cell grey-brown, gradually becoming dusted with velvety blackish; under surface reddish brown, clouded and marbled with darker. Near the base and across the end of the cell a dark brown band, the latter broadest at the costal margin; in the costal area a small white spot. At the apex whitish dusting and near it three small black dots. Hindwing almost oval. Distal margin without appreciable angle, but the hinder angle rather prominent. Upper surface grey-brown with faint rust-red tone, distal margin somewhat lighter, red-brown; costal margin light brown, a bare friction-area with small yellowish pilose spot before the subcostal blackish. — Under surface brown, near the base darker, further posteriorly with three reddish spots. From the costal margin to the anal angle runs a dark brown

band, behind the middle distally bordered with whitish, and beyond the cell an undulate row of small black spots, of which the two nearest to the hinder angle are dotted with white. Ecuador.

cyllabarus. **N. cyllabarus** *Westw.* Apex of the forewing rather pointed, distal margin slightly convex. Upper surface rust-brown or fox-red, towards the distal margin somewhat darkened; the latter itself pale brown, the dark tone thus forming a vague band. Before the anterior median vein near the distal margin a black, white-pupilled spot. Under surface ochre-yellow, spotted and marbled with brown, but not sharply. From the costal 2 diffuse transverse bands across the cell; from the whitish apex an oblique, diffuse nebulous band runs towards the middle of the inner margin. A black dot in the distal part of the cell and another between the radials before the distal margin. Hindwing likewise rust-brown with distinctly defined dark submarginal band. Under surface pale brown, costa striated, in the middle of the costal area a dark, white-pupilled spot; the rest of the wing indistinctly spotted and marbled with darker; across the middle of the wing a diffuse dark oblique band. Scent-spot as in the preceding species. Cayenne, Colombia, Amazons, Bolivia.

panniculus. **N. panniculus** *Stich.* ♂: head, palpus, antenna, body and upper surface of the wings smoke-brown, in specimens from Bolivia darker, nearly blackish. Forewing right-angled-triangular, costal margin curved, apex sharp, almost rectangular, distal margin fairly straight, hinder angle rounded-rectangular, hindmargin straight, about in the middle somewhat folded. In the posterior part of the median area a large, rounded, velvety spot of darker colour; this is placed proximally to the cell, its anterior extremity nearly touches the upper median vein, distally it remains about 5 mm. from the margin of the wing and posteriorly it extends beyond the submedian but with its boundary not sharply defined. Under surface lighter, irregularly spotted. Base darker shaded, then 2 abbreviated nebulous bands across the cell, in the apical area a small white spot; scent-organ as in the preceding. Hindwing above unicolorous with light oval scent-spot. Under surface lighter, slightly sprinkled with brownish, with indistinctly defined nebulous band beyond the cell; beyond the middle of the costa a small white dot. Paraguay, Bolivia (Rio Yuntas). 1 ♂ from Matto Grosso in coll. FRUHSTORFER is smaller than Paraguay ♂♂, paler grey-brown, beneath light earth-coloured, hindwing with large liver-like intramedian ocellus, broadly filled in with white.

Hindwing of the ♂ above without scent-spot, but with a small hair-pencil arising in the cell and partially concealed in a pouch-like fold.

albopunctum. **N. albopunctum** *Stich.* Head and body smoke-brown above, whitish grey-brown beneath. Wings dark smoke-brown above, without markings except a small, pure white spot in the apical area behind the fifth subcostal vein, near the distal margin. Under surface marbled and shaded with lighter and darker brown. Costal margin dark, with short whitish striation. Starting from it two dark, irregularly defined transverse bands, one across the cell, terminating at the median; at the margin near the base a thin, anteriorly directed hair-tuft without scent-scale spot. Hindwing about triangular, with convex margins. Costal margin somewhat less convex, apex rounded, distal margin curved, slightly undulate, at the anterior median vein obtusely angled. Hinder angle obtuse. Upper surface without markings, hindmarginal area more thinly scaled, pale grey-brown, in the cell and along the submedian long brown hairs. On the wall of the cell, before the origin of the posterior median vein, a small hair-pencil, extending beyond the median, and partially concealed in a pouch-like fold on the lower median. Under surface brownish, strongly watered and dotted with whitish, particularly in the proximal half, which is sharply bounded by a narrow brown stripe running obliquely from the distal part of the costal margin to the distal quarter of the hindmargin. In the distal part of the wing an undulated row of black-brown, lighter-bordered dots, about halfway between the end of the cell and the margin of the wings; the first dot sometimes with white centre. Then follows a vague chain of dark spots similarly arranged and afterwards copious whitish marbling, the distal margin narrowly brown. Length of the forewing 28 mm. Peru (Marcapata).

Addenda.

fruhstorferi. **P. 293.** *Opsiphanes fruhstorferi* *Röb.* (63 a) should be inserted before *sulcius*. Black-brown above, the forewing with white oblique band, broken in its posterior part, arising in the middle of the costa and terminating in a narrow point before the distal margin at the posterior median vein. In the apex of the forewing 3 small white spots, hindwing with lighter, irregular, broad submarginal line. Under surface brownish grey, uniformly striated, with 2 larger, and between them 2 smaller ocelli. ♀ similar, larger, the apical spots of the forewing and the submarginal line of the hindwing more distinct. South Brazil: Sta. Catharina, Lages. Very local; I found it only at the sources of the Uruguay, where the water-courses traverse those wooded places which occupy the valleys of the Campos. The butterflies fly near the ground and regularly frequent the sap exuding from small trees, at which they feed for hours. Time of flight the end of December to February and March.

6. Family: *Morphidae* Westw.

This small family embraces the most strikingly characteristic butterflies of South America and the most magnificent of the Lepidoptera, which show the butterfly type in a perfection that is only surpassed by the Indo-Malayan *Ornithoptera*. The brilliant colouring of the upper surface and the elegant ocelli which nearly always adorn the under make the *Morphidae* superficially a very distinct, easily recognized group. It is not very easy, however, to separate them morphologically, for in spite of the external differences there are only indefinite structural distinctions from the Brassolids, Satyrids and Nymphalids and they form rather a transition from the Satyrids to the Nymphalids, so that they can only with difficulty be maintained as a separate family. Also from the Indian Amathusiids, which were formerly united with them, they only differ essentially in their habits and the food-plants of the larvae. All the Morphids agree in the weakly developed thorax, short abdomen, and in an extraordinarily powerful flight, which latter at once separates them from the sluggish Satyrids, Amathusiids and Brassolids. They share with the Nymphalids the habit of flying in the brightest sunshine, and structurally the open cell of the hindwing. With the Indian Amathusiids the Morphids are indeed somewhat allied in having larvae of the same shape, but differ again in the food, as the larva of the Amathusiids feeds on Monocotyledons, that of the Morphids, as far as is known, exclusively on Dicotyledons. From the bulk of the Amathusiids their Neotropical relatives differ in having two subcostal veins arising before the end of the cell on the forewing, a form of neuration which is only found again quite exceptionally in the Taenarid genus *Hyantis*. In the clasping-organs, however, the Morphids are highly specialized, and although the general arrangement of the tegumen suggests the Satyrids and Brassolids, those of *Morpho* differ in the extremely massive, unshapely uncus and valve. In some species (*Morpho hercules*) the breadth of the uncus actually exceeds that of the valve in the other families and is not equalled even in the Nymphalids. The robust uncus only recurs in the Brassolids (*Dynastor durius*) and even here considerably less extreme; the valve finds an analogy in the Papilionids (*Ornithoptera*) and in *Hestia*. The amorphous lateral clasps of the uncus, however, are entirely without a parallel. In the neuration may further be mentioned the fairly similar course of the discocellulars and their nearly uniform length. In the nearly straight middle and lower discocellulars the Morphids and Brassolids contrast with the Amathusiids, in which the lower discocellular is as a rule concave and deeply retracted proximally. The precostal cell of the hindwing may be distinctly developed (*Morpho menelaus*) or absent (*M. catenarius*), in the former case providing a further link with the Brassolids, in the latter with the Amathusiids. The median spur of the forewing also, on which Dr. SCHATZ lays special stress, is variable: either robust, short and pointed or filiform and distally curved, as is found also in the Amathusiids. The size of the cell of the forewing varies in the different groups of species; it is large in the *menelaus*, smaller in the *hecuba-hercules* group. GODMAN and SALVIN in 1881 recognized two subdivisions according to the shape of the hindwing: a) with tailed (*hecuba* group) and b) with rounded hindwing (*cypris* group). Between the two stand the members of the *aega* group with elongate, narrow hindwing. Dr. SCHATZ divided the species into six subdivisions, according to the scheme of colouring. The coloration of the 40 or so known species is indeed unusually variable and may be pure white or brilliant blue; between these come the members of the *hercules-hecuba* group with all gradations from light yellow to dark green and a dull chalky blue. The degree of sexual dimorphism is quite as variable as the colouring; species occur with the sexes almost alike (*laertes*, *hecuba*, *hercules*), whilst the *rhetenor-cypris* group shows astonishing contrasts in colour. It is worthy of note that just those ♂♂ which have the brilliant *Morpho* colouring (*cypris*, *rhetenor*) consort with almost ugly clay-yellow or dull ochreous ♀♀, which still tend to retain the colour of the Brassolids, from which the Morphids have probably developed. In a few species, however, transitions also occur.

The brilliant gloss of the ♂♂ is solely a physical phenomenon and is not due to any blue pigmentation in the scales, but to interference of the rays of light which pass through the infinitely thin layers of the scales. The scales themselves are simple yellowish to brownish, or opaque milk-white, extremely resistant in the chloride bath. The eyes of all the Morphids are naked, the antennae delicate, gradually terminating in a weak club. Apart from a friction-area at the basal part of the inner margin of the forewing no secondary sexual characters are present. One species is said to smell strongly of sulphur.

The egg of the Morphids is very large, in some species (*menelaus*) up to 2 mm. in diameter, hemispherical, not shiny, grey-white and but little transparent. In the species of the *achilles* group it has a narrow red-brown horizontal ring, in one species (*peleides*) the surface is rough (FÄSSL).

The larvae live in nests on different forest-trees and especially on the climbing plants, but attack one another. There are about five moults. Larva cylindrical, rather slender, somewhat thickened in the middle, tapering posteriorly. The last segment terminates in an indistinct tail-fork. The head is comparatively large and bears a pair of horizontal, conical processes, directed anteriorly, which are sometimes only rudimentary. Colour always bright, sometimes variegated, yellowish with red-brown dorsal stripes or cross-shaped figures, back with long subdorsal tufts of bristles, of which the middle and posterior are in some cases gaily coloured. Pupa similar to that of the genus *Amathusia* but more oval. Head with two tubercles, wing-cases distinctly projecting, abdomen sometimes belted with yellow; colour green or yellowish. Pupa on twigs or leaves attached by the abdomen but hanging free. The pupal stage lasts 20—30 days.

The Morphids, especially the entirely blue species, form on account of their brilliance a characteristic of the South American landscapes. They strike every naturalist and mention of them recurs in works of travel with the same stereotyped regularity as the description of the parrot's flight or the abundance of the humming-birds.

The author of these lines had the pleasure of himself observing Morphids in the woods of Sta. Catharina, but especially in a lonely side valley of the Capivary River, which at that time was still little explored by white men. A crystal waterfall sprinkled the roots of the forest giants, providing a point of attraction for butterflies of all kinds. Just as wild animals tread down regular tracks in order to reach water, so the Morphids assembled here daily, following up any chance clearings to get to the cascade, as if they came to seek cooling refreshment among the softly rustling arches of the tall bamboos, which were shaken and bedewed by the foaming water. They did not come in crowds but singly, floating along quietly. And how patiently one waited, until after some minutes of silent expectation a second iridescent form appeared, to be captured with the almost unfailing certainty of long practice as soon as it ventured within reach of the net.

The magic impression which the Morphids make on the European traveller seems to be shared also by the natives. Dr. KOCH tells us (*Archiv für Anthropologie*; Brunswick, 1906, V, part 4, p. 295) that *Morpho menelaus* is chosen as a favourite model for the dance-masks of the red-skins on the Upper Rio Negro and Yapura Uaupes.

The habits of the separate species differ very much. Some, such as *achilles* and *deidamia*, fly unsteadily at the edges of woods or along the forest-paths which intersect the tropical forests and commonly settle on leaves or damp places on the ground or on the river-banks, also on fallen fruit. One species (*catenarius*) prefers the underwood, is even found near human habitations and can be baited in rather large numbers with hung-up bananas. The species of the *hecuba*, *menelaus* and *rhetenor* groups, however, avoid the ground; they never leave the timber-forests and soar round the tops of the highest trees without appreciable movement of the wings. In Ecuador it has been observed that the species of the *M. menelaus* group, which were flying along a small wooded branch-valley, stopped short on the bank of a broad river and flew back into the shade, not venturing even to cross a short open space in order to reach the other wooded bank.

The range of the Morphids extends over the whole of tropical and a part of subtropical America, from Mexico as far as Southern Brazil and Northern Argentina. The Amazon is its headquarters, particularly the streams which run down the eastern Cordilleras of Ecuador and Peru and form the sources of that river. On the Antilles no *Morpho* has yet been found, except on Trinidad, which in other respects also can scarcely be separated zoogeographically from Venezuela. Concerning the vertical distribution reliable information is wanting, but it is certain that some species occur up to about 2000 m. The alpine regions are avoided by the Morphos as by the Hestias or Amathusiids, as the shape of their wings is adapted to the protection of the woods. The period of flight of the Morphids is in general a very short one and it may be assumed that, except in the pure tropics, they everywhere occur (as in southern Brazil, where the author has been able to observe them himself) only in the height of the tropical summer, thus in the most favourable time for the development of the butterfly life. In consequence of their not being on the wing all the year round, like many Nymphalids and Pierids, they are only in quite rare cases subject to the influence of climatic contrasts and seasonal variation is only known with certainty in two species (*perseus* and *portis* Hbn.). On the other hand almost all the species are subject to a high degree of geographical modification, forming separate races whose identity with the collective species must often remain doubtful, especially at the extreme limit of their range, and one may assume that in the Amazon region in particular a distinct local form is developed on every important tributary. This phenomenon recurs in the different Brazilian provinces and it is astonishing that it was left to me to notice and to establish this fact.

The examples figured are from the H. FRUHSTORFER collection at Geneva, which also contains the types of the newly described forms, except where the collection in the Zoological Museum at Berlin is mentioned as the source. Dr. K. JORDAN was kind enough to send some types from the FELDER collection in the Tring Museum for comparison, with the help of which I have been able to correct some long-standing errors, espe-

cially some for which Dr. STAUDINGER was responsible. I have to thank Dr. JORDAN most sincerely for his valuable help.

Genus: *Morpho* F.

Two groups: a) Hindwing with projecting tail-like appendage or deeply sinuate. Upper surface without metallic sheen; tegumen with unusually broad lamellae. *Iphimedeia* nom. nov.

b) Hindwing as a rule rounded or only slightly waved, upper surface (only one exception) with brilliant reflection; tegumen with finger-shaped excrescences. *Morpho*.

Group *Iphimedeia* Fruhst.

Species without metallic gloss on the upper surface, which varies from greenish blue to whitish in all gradations. The colouring very inconstant, the extremes sometimes not even confined to any fixed locality. Upper discocellular long, middle only inappreciably concave (i. e. proximally curved), the lower straight and placed at right angles to the anterior median. Cell of the forewing very narrow at the apex. Uncus broad, lateral clasp strikingly flat, valve without distal points. Most species love the sunshine, ascend to a great height and fly exclusively round the tops of tall trees.

M. hercules is confined to central and southern Brazil, where it occurs from Espiritu Santo to Sta. Catharina and ascends from the lowlands to about 800—1000 m. Flies chiefly in March. Concerning the early stages I am indebted to the detailed account furnished by Herr ZIKAN, who has bred *M. hercules* from the larva in Minas Geraes and whose report of his breeding we here reprint:

"*M. hercules* has one generation and flies in February and March. The eggs are laid on the leaves of a climbing plant (Cipó) with thick hard leaves (somewhat resembling those of the coffee-tree) and yellow fruit. This Cipó becomes rather thick and grows even in the highest trees. It seems to me to prefer dry ground and the tops of mountains. When small the larvae rest closely pressed together on a leaf which they cover with web as they do also the twigs on which they crawl to their food. I found them in numbers varying from 17 to 150 specimens; once even about 300, but I suspect that the latter came from more than one batch of eggs. I noticed that the butterfly prefers to lay its eggs in the decumbent tips of the Cipó, sometimes even quite low, about the height of a man and even lower. Others again I found very high, so that it required some courage to fetch them down from the giddy height. The first larvae (150 specimens) were found on the 30th September 1907. Most of them were moulting. They were about $1\frac{1}{2}$ cm. in length, apparently after the first moult, as they underwent four more moults in captivity (including pupation). On the 13 October the first two larvae performed the second moult in captivity. When collected the colour of the larvae was red, body hairy, dorsal line lighter, with hair-tufts on both sides, the longest hairs being white. Head large, dark red, nearly black. After this second moult the hairs became denser and longer, especially at the sides. By 30 October all but twelve had moulted; four specimens had died, being stung by dipterous parasites. On the 10 November I noticed the first larva had completed the third moult; by the end of November most of them had moulted. Before the fourth moult, that is before pupation, the larva changes to a dirty green colour. I found the first larva in this condition on the 17 December and the first pupa the 31 December; on the 27 January the last larva pupated. From about 1200 larvae I obtained 800 pupae. Very many of the former were stung, without exception by flies. Others again dried up and went mouldy. The pupa is green, ringed with white. The colour scarcely changes appreciably before the emergence of the butterflies. The pupal stage lasts in the ♂♂ 45—52 days, in the ♀♀ 57—60 days. The first butterfly emerged on the 4 February 1908, the last on the 21 March. In addition to the ♀♀ having a longer pupal period than the ♂♂, their larvae also appear to pupate later. For from the 19 to the 25 of February only 20 ♀♀ emerged; whilst from the 26 February to the 1 March only 9 ♂♂ emerged, against some 170 ♀♀. About 50% of the pupae died, mostly dried up. When one broke them open they were mouldy inside. I lost a large number of larvae through their being too crowded, other larvae disturbing and knocking them down when they were pupating. Although I found the larvae of this butterfly in such abundance I have only seen about a dozen butterflies in the open. They fly high like *Morpho nestira* and not like *M. achillaena*, which keeps about 1 m. above the ground.

With regard to the larvae I may add that it is best only to take them in the adult stage; when collected young they do not grow properly, as every time they are given fresh food they spin over it so as to get a foothold, and in this way much nourishment is wasted. From those larvae which I collected when small I obtained quite small butterflies, while those which were taken large yielded large and more brightly coloured specimens. The hairs of the larva easily become detached, penetrate into soft places in the skin (between the fingers, etc.) and cause irritation. The larvae live gregariously until pupation. They feed at night; in the adult stage they sit during the day underneath the Cipó or on the trunk of the tree round which is winds. When small they sit on the spun-up leaves."

The pupa differs from that of *M. anaxibia* in the longer, more robust form, the more developed horns

on the head, the much darker green ground-colour, the absence of the white abdominal ring and the presence of whitish yellow lines before the margin of the wing-cases. The collective species splits up into two local races:

hercules. **hercules** Dalm., originally described from Rio de Janeiro, but also occurring in Minas Geraes and Espiritu Santo. Upper surface more grey-green than in examples from more southern localities. Upperside of the forewing with two rows of submarginal yellow dots, of which the proximal are considerably broader than the antemarginal. Patch before the apex of the cell narrow, dark green, subobsolete. Cell black-green. Discal area glossy dark green. Distal border broad, deep black. Base of the forewing dark, of the hindwing somewhat lighter sea-green. Under surface: forewing bearing two very large rounded ocelli between the medians and two much smaller ones between the upper radial and the upper median. The proximal median spots narrow, irregular. Discal spot black. Cell with two very broad white longitudinal bands, posteriorly confluent. Hindwing predominantly red-brown with silver-white median band about 3 mm. in breadth. 3 anal ocelli with black iris.

diadema. Length of the forewing 90 mm. and upwards. Espiritu Santo to Rio de Janeiro. — **diadema** Fruhst. (69 a). Upperside of the forewing with two rows of submarginal yellow dots, the proximal row only in the ♀ essentially broader than the antemarginal. Patch before the apex of the cell very broad, sharply defined, yellow-green. Cell dark olive-green. Discal area dull olive-green. Distal border broadly brown-black. Under surface: forewing with only two, very large, circular ocelli between the medians, the upper sometimes wanting. A third, small diffuse ocellus between the radials is sometimes present. The proximal, triangular median spots somewhat smaller than in *M. richardus* (p. 337), larger than in *hercules*. Cell with 2 isolated white, posteriorly pointed spots. Hindwing in the ♂ predominantly whitish grey with the basal part light brown, in the ♀ grey-white, marbled with light brown. Median band 5—6 mm. in breadth. 3 anal ocelli, of which the distal, with light brown iris, is occasionally obliterated. Length of the forewing: 75 mm. or above. Larva according to Dr. WILHELM MÜLLER on a *Menispermia*, gregarious, in the last stadium occasionally resting in masses of over a hundred individuals, one beside another, on the trunk of the trees up which the food-plant climbs. They remain quiescent during the day, only feeding at night. Ground-colour somewhat brown-red with a lighter red-yellow dorsal stripe and numerous spots of the same colour, almost fused into a lateral stripe. Head yellowish, with long bristles. Pupa with weak edges to the wing-case, green, not transparent, partially marked with white and covered with a white mealy coating which can be rubbed off.

M. theseus apparently replaces *hercules* in Central America and the Andean region. It is less constant than *hercules*, inclining to geographical and probably also to climatic variation, has somewhat narrower wings than *hercules* and is distinguished from all other Morphids by the long, pointed teeth of the hindwing. —

aratos. **aratos** Fruhst. (66 c), the most northerly subspecies, inhabits Honduras and like all its Central American allies is among the greatest rarities of the fauna of their region. I have only received one example, which WITTKUGEL found during about 10 years' collecting near San Pedro Sula in Honduras. Ground-colour of both wings above and beneath paler than in its nearest ally, *M. justitiae* Godm. & Salv. from Guatemala. On the upper-side of the forewing the third inner (proximal) submarginal row of dots (which is especially strongly expressed in *justitiae*) is obsolete. — **justitiae** Godm. & Salv. has the yellow transcellular spot on the forewing more than three times as broad. The submarginal crescents of the hindwing are more elongated; the black colouring of the distal part of the hindwing extends to beyond the middle of the wing. Under surface red-brown instead of grey-yellow as in *aratos*. Ocelli of the hindwing more filled in with black. The locality "Mexico", which

aquarius. GODMAN and SALVIN recorded from an old example from coll. DRUCE, has not been confirmed recently. — **aquarius** Btlr. designates a well differentiated form, which occurs from Costa Rica to Panama as a subspecies, but in Colombia is still found as an accidental or seasonal variety together with the name-type *theseus* at Muzo, 400—800 m. *aquarius* has the basal area on the upperside of both wings chalky or milk-white, the original brown ground-colour confined to the submarginal region. The third (proximal) row of spots on the forewing, which stands on a light brown ground, assumes a blue-grey colouring. On the hindwing the pronounced yellow patches of *aratos* and *justitiae* disappear almost completely. The under surface is distinguished by a whitish violet postmedian area proximally to the ocelli, which is absent in *theseus*. Transitions to *theseus* are not

theseus. rare in Colombia. — **theseus** Deyr. is the Colombian typical form, found in Muzo and in so-called Bogotá consignments, which it is well-known really come from the low-lying country, just as the so-called Darjeeling collections were likewise not made at Darjeeling, but in the hot valleys of the Testa. Ground-colour brown inclining to olive-green, base only quite faintly suffused with whitish. Cell black-brown at the extremity and with an inconspicuous whitish spot before the apex. Forewing with only two distinct rows of yellowish patches.

thiasus. Under surface red-brown with purple gloss, in places reddish ochre-yellow. — **thiasus** subsp. nov. is based on examples from coll. STAUDINGER with the upper surface darkened throughout, brown-black. Colombia, more

amphitrion. exact locality not ascertainable. — **amphitrion** Stgr., from Chanchamayo, South Peru, has the forewing much elongated, with the cell blue-grey. ♂♂ also occur with the upper surface suffused with blue-white throughout. —

susarion. **susarion** subsp. nov. is the most southern Andean branch-race, with somewhat darkened upper surface and of smaller

yaritanus. size than the Peru race. Bolivia, apparently not rare. — **yaritanus** subsp. nov. constitutes the transition from *theseus* to *aratos* and *aquarius*. It agrees with *aquarius* in the extended milky blue basal tinge on the upper surface

and with *aratos* in the very large, rounded, light ochre-yellow submarginal spots of the hindwing, and the forewing is distinguished by a large blue-white transcellular spot and very large blue-grey proximal submarginal dots. The under surface closely approaches *theseus theseus* Deyr. from Colombia in the predominantly red-brown colouring and the extended ochre-yellow areas. Always rare and local. Venezuela. — A further, very rare local race of *theseus* (but smaller than all the others), hitherto treated as a species, is *juturna juturna* Btlr., recently captured by FASSL on the upper Rio Negro at about 800 m.; hindwing with long lobes and upper surface a peculiar blue-white, faintly opalescent; distal border rather broadly black-brown and bearing on both wings a row of blue-white submarginal patches and a subterminal double row of red-brown undulate lines. Cell of the forewing separated from the transcellular white area by a broad, black, nearly triangular spot. — *fruhstorferi* Rōb. is the corresponding race from the Eastern Andes, of which only one ♂ is yet known, discovered by Herr RICHARD HAENSCH at Santa Inez, East Cordilleras of Ecuador. It differs from *juturna* in the chalk-white upper surface without blue or violet admixture and the more pronounced yellowish subapical patches of both wings. Found at an elevation of about 1000 m. *fruhstorferi*.

M. perseus is an extremely variable polychromatic species, resembling a *hecuba* in miniature and copying its scheme of coloration. *perseus* with its branches inhabits the whole of Guiana and the Amazon country as well as the Andean region from Colombia to Bolivia, and was recently discovered also in Central Brazil. According to MICHAEL *perseus* is never seen fluttering round flowers, nor do the butterflies seem to require food or drink. They prefer rather to soar through the spaces of the illimitable forests like *Morpho hecuba* or to float along in unrestricted flight over the tops of the trees in a deep valley. According to HAHNEL *perseus* is one of the highest-flying Morphids and on account of its brown under surface, which looks very dark against the light sky, it gives the impression, when flying at a height of 8—10 m., of a black-coloured species. HAHNEL says that the butterflies, which in spite of their lively, jerky movement through the air scarcely flap the wings appreciably, present a charming spectacle, particularly when half a dozen or more meet and engage in a sham fight. Almost the whole morning such scenes are repeated, for only towards midday, after they have been flying over their wide domain for 2 or 3 hours, do their pinions become weary and they settle again in the shade of the branches on some large leaf, the back turned towards the dark and the eyes towards the open. One rarely finds even a single insect flying in the afternoon and then probably only when unfavourable weather has hindered its doing so in the morning. The butterflies occasionally dart down on to yellow *Papilio* ♀♀ drinking on the ground, undoubtedly taking them for their own ♀♀, which are also frequently yellow, and Dr. HAHNEL took advantage of this by fastening pieces of yellow paper in his net, which actually deceived the *perseus* ♂♂. *perseus* Cr. describes a ♀ form with the basal part of both wings light blue. *crameri* Kirby is the ♂ belonging to it, with the blue ground-colour sometimes somewhat darkened. *metellus* Cr. on the other hand designates ♀♀ with an ochre-yellow median band, deceptively like the colouring of *M. hecuba* L., which flies at the same place. All three forms were obtained by CRAMER from Surinam. The larva is gregarious, only feeds for a short time and remains quiescent for the rest of the day. At Villa Bella on the Lower Amazon HAHNEL took examples with the upper surface inclining to bluish or brown, and on the Upper Amazon, judging from the STAUDINGER collection, ♂♂ occur most commonly with ochre-yellow bands tinged with green, at Iquitos ♂♂ with dark green, and ♀♀ with green-blue median area. There are also light blue (typical *perseus*) from Villa Bella in the Berlin Museum. The particular colour is, however, apparently nowhere restricted to particular localities, though MICHAEL once bred 12 specimens from the larva on the Rio Madeira, the whole of which were pale grey-green above. — *iphielus* Fldr. is a local form from Colombia with three distinct rows of yellow submarginal patches, whilst in the Amazon specimens the proximal row of dots is only indicated by three or four small scattered spots reaching as far as the middle of the wing. One ♂ in my collection, from Surinam, shows indeed only a couple of indistinct patches on the forewing. A ♀ which FASSL took on the upper Rio Negro at about 800 m. is remarkable for an extended light clay-yellow circumcellular area on the forewing, which reaches to the middle of the wing and is there lost, giving place to the pale green basal colouring. Hindwing as far as the cell light green, the discal area black-brown. Forewing with three rows of ochre-yellow patches, of which the proximal terminates near the posterior median, the middle is composed of large triangular spots, the rows, except the third (proximal), continued on the hindwing also. Cell of the forewing lightly dusted with greenish yellow along the posterior wall. Under surface a peculiar dull grey-yellow with yellowish median area, two large median ocelli on the forewing and somewhat ill-defined eye-spots on the hindwing. — *scipio* Fldr., with the incorrect locality "Brasilia meridionalis", which should perhaps read "Brasilia septentrionalis", is near the form *metellus* Cr., agreeing with it in the ochreous median area of the upper surface and the washed-out submarginal patches. Habitat without doubt Surinam. — *richardus* Fruhst. (69 a), from Minas Geraes, differs most considerably: ♂ of indefinite greenish, ♀ of yellowish bronze-green colour, both above and beneath deceptively like a small *M. hercules* Dalm. I have only three examples before me, which were bred from the larva and killed too soon. Forewing with 3 rows of submarginal yellow dots. The patch before the apex of the cell broadly dull gold-yellow, with scattered black scales. Discal area of the forewing yellowish. Distal margin rather narrow, brown-black, base of both wings light green. Under surface: forewing with four small, elongate ocelli of about uniform size, with narrow black irides. Proximally to the ocelli three *iphielus*. *richardus*.

very large, triangular grey-yellow median spots. Underside of the hindwing predominantly red-brown, with violet sheen. Median band grey-violet. Length of the forewing 58 mm.

M. hecuba is the largest known *Morpho* and one may also call it the most interesting, on account of its habits, its susceptibility to climatic influences and its tendency to develop polychromatic forms in both sexes. We are indebted to Dr. HAHNEL for the most detailed information of its habits of flight. HAHNEL calls it the king of the forest, and says that it traverses a wider area than any other butterfly, travelling perhaps 30 km. or more in two or three hours, continuous flight in quest of its mate, which it follows persistently for whole days, quite alone, over woods and water-courses. In the distance the flight of *Morpho hecuba* looks quiet and slow, but nevertheless it moves quickly enough to evade the collector and newly emerged insects in particular adopt an impetuous pace during their first hours of flight. Sometimes it happens that one of these apparently quietly hovering forms suddenly darts head downwards, and in this event it seems only to rise again with difficulty. They are driven to these violent erratic movements by dragon-flies, which lie in wait for them especially in marshy places and molest them from the tips of dry twigs, apparently more out of wantonness than from a desire to catch them. — *hecuba* L., the name-type, is distinguished by the contrast between the reddish brown forewing and the nearly black hindwing, which is only basally relieved with yellowish white. Forewing with yellowish, hindwing with white cilia. The under surface is remarkable for the silvery bands, which in nature are even clearer and more brilliant than in our figure (67 c). *hecuba* is one of the rarest butterflies and exclusively inhabits Surinam. What is labelled as *hecuba* in collections and sold as such by English dealers is a very similar local form but differing considerably, especially beneath, namely *obidonus* Fruhst., which only occurs on the north bank of the Lower Amazon. Of the numerous differences from *hecuba hecuba* L. the following may be mentioned: The distal black border of the forewing is broader, the proximal (inner) submarginal row of yellow spots consists of rounded instead of elongate patches. The basal area of both forewing and hindwing is not yellowish but chalk-white. Abdomen conformably with the basal colour pure white, not yellowish as in *hecuba*. The reddish submarginal spots of the hindwing absent; all the cilia of the hindwing pure white, while the upper cilia of *hecuba* are yellowish. The coloration of *obidonus* beneath is still further removed from the type, the ground-colour of the former being predominantly black, that of *hecuba* red-brown. *obidonus* is further characterized beneath by the absence of the ultracellular red-brown triangles between the median veins of the forewing. The ocelli of the hindwing are smaller, with reduced black iris, but still as complete as those of *hecuba*, and not posteriorly open as on our figure; the latter belongs to a hitherto unnamed race from the Middle Amazon, *heracles* subsp. nov. (67 c), in which the bordering of the ocelli is not rounded but horseshoe-shaped. *heracles*, however, agrees with *hecuba* in the double row of reddish submarginal patches on the upperside of the hindwing. Dr. HAHNEL only three or four times saw *obidonus* floating high up through the branches and over the tops of the trees, and did not catch any. Dr. STAUDINGER only received his first *hecuba* ♂, which probably belonged to the form *heracles*, through the artist OTTO MICHAEL from the Rio Negro and my experienced collector JULIUS MICHAELIS sent me about 30 or 40 examples, which he captured in July and August with the help of a stick 4 or 5 m. in length, on which an unusually large net was fastened. The ♀ of *hecuba* and *hecuba obidonus* is considerably larger and has somewhat rounder wings than the ♂, with more strongly marked yellow and reddish submarginal patches on both wings, somewhat paler black distal area on the upperside of both wings and lighter yellow-brown under surface. According to MICHAEL (Iris 1894, p. 197) *obidonus* has a short season of flight (June and July, once observed also in December). Fresh examples appear after every thunder-shower, but they already become less numerous on the second and third day, and the fourth one only sees a specimen here and there, and afterwards only worn examples are seen; ♀♀ nearly always sit still where ♂♂ will be passing, in any case they only occasionally fly a short distance in the morning. — *cisseis* Fldr. (= *egyptus* Deyr.), from the south side of the Lower Amazon, is distinguished in the ♂ by dark, in the ♀ by lighter blue and rather narrow bands on the forewing. On the hindwing the basal area is somewhat more extended than in *hecuba* and *obidonus heracles*, according to the sex lighter or darker blue, the blue with slight mother-of-pearl gloss and the submarginal area adorned with blue-white lunulate spots. At Itaituba on the Tapajos occur more commonly light blue, more rarely dark blue, or even dark violet ♀♀. In Ecuador and even in Bolivia the colour-scheme of *cisseis* is retained, yet in these countries the ♂♂, and occasionally also the ♀♀, sometimes assume a brownish colour. — *cisseides* Fruhst. The black which occupies the cell of the forewing extends somewhat beyond its apex, and in addition the blue spot before the apex of the cell is obsolescent, being only indicated by a little dusting. Of *cisseis* BATES writes that the butterflies present a magnificent spectacle as they sail along by twos or threes at a great height in the still air of a tropical morning. But according to Dr. HAHNEL *cisseis* only awakes when the high-flying *perseus* have already long been floating over the clearings, in the distance looking like black spots, when the sun has begun to beat down with full power on the leafy dome of the forest and *M. menelaus* has finished its flight. *cisseis* then moves slightly forward on the leaf on which it passed the night, and opening the wings it slips with a bound into the air, rising lightly to the tops of the trees, among which it takes its flight until the clearing of the road appears, which

it now follows, pursuing its way quietly and steadily, with the powerful wings scarcely quivering. It looks then like a narrow silver-blue stripe, in the vestal purity of its delicate white colour, which from the middle towards the costal margin changes into a light blue, posteriorly into black. The silver-white and brown of the under surface, however, present an excellent copy of large withered leaves covered with mildew at the veins, the similarity indeed being so great when it is resting in the shade of the branches that at Villa Bella Dr. HAHNEL once took a newly emerged example hanging on the pupa for such a withered leaf, until to his amazement he proved it to be a living form. According to MICHAEL (Iris 1894, p. 197) *cisseis* flies in every month, thus all the year round. — At Iquitos and Yurimaguas on the Upper Amazon *cisseis-obidonus* is replaced by **phanodemus** Hew., the forewing of which in rare cases still bears traces of the *hecuba* colouring and is in part somewhat brown-yellow with the marginal area only slightly blue. But examples with green-blue median band seem to be the commonest, this colour sometimes distally changing to olive-green or greenish brown and towards the base to light blue and white. In the ♀ the shades of colour are less ill-defined and there occur pure and uniform light, dark, steel- and green-blue tinged specimens, to which it may be left to others to give special names. The under surface agrees completely with our figure 67 c, although it is only exceptionally that the apical ocelli of the hindwing are accompanied posteriorly by a small accessory eye-spot, as in the example from which the figure was drawn. Dr. HAHNEL calls *phanodemus* a kingly form and compares it, in its quiet, peaceful and ghost-like flight, to the tutelary genius of the secret of the forest. HAHNEL was only able to obtain *phanodemus* by erecting a sort of scaffolding of bamboos, which he set up to a height of about 5 m. in the line of flight of the Morphids. In order also to secure the *phanodemus* which came up from behind a mirror was fixed on the parapet of his tower, which indeed was not often successful, but when it was, gave all the greater satisfaction. — **polyidos** subsp. nov. has a very broad black distal margin to the forewing, increasing in width from the costal margin to the anal angle, but the submarginal patches are only slightly indicated. The cell of the forewing contains only a few yellowish patches, the median band itself much narrowed. Hindwing basally pale yellow, distally lightly dusted with greenish. Under surface as in *hecuba obidonus*, except that the ocelli of the hindwing are somewhat smaller. From Itahapa Yarita in Venezuela, collected by VRAZ. Type in coll. STAUDINGER in the Berlin Museum.

Group *Morpho F.* (= *Leonte Hbn.*).

Species with metallic gloss on the upper surface; upper discocellular short, middle strongly convex proximally, lower concave distally, in the obtuse angle directed towards the anterior median. Cell of the forewing considerably widened towards the apex. Uncus and its lateral clasps relatively slender, valve distally spined.

M. laertes is the best known of a small group of species which differ from all their allies in the chalky, milky or silvery white ground-colour. *laertes* may be easily known by the connected chain of narrow, oblong, ocellated median spots on the underside of the hindwing, which have mostly only indistinct white pupils and washed-out yellowish bordering. The bluish white colouring is brought out very well in the figure. The upper surface resembles the figured underside, except that the forewing continues narrowly margined with black to about the middle of the median area. Hindwing with some elongate black anteterminal and more distinct submarginal patches. *laertes* only inhabits the provinces of Rio de Janeiro and Espiritu Santo and is very common both at Rio and Petropolis from January to March. Larva in nests on various forest-trees. It was first figured by BURMEISTER. Arrangement of the bristles according to Dr. WILHELM MÜLLER as in *Morpho hercules*. Two sharply differentiated local races: **laertes** Druce (= *epistrophis Hbn.* [pro parte] ♀, *iphaeus Fldr.* ♀) (68 c), relatively small, apical patch on the forewing above narrow, as also the black curved spot at the apex of the cell; ♀ with sharply defined black-brown submarginal crescentic spots on the underside of the hindwing. All the markings yellow-brown, the intramedian ocelli of the forewing strongly marked, rounded, ♀ bright yellowish green, with mother-of-pearl gloss. — **eutropius** subsp. nov. Larger than *laertes*, ground-colour both above and beneath more blue-green. Forewing with the apical patch more than twice as broad, the black hook at the discocellular more strongly marked. Hindwing in both sexes further with a subterminal series of intraneural striae, united into a median and an anal undulate band; under surface with the markings blackish instead of yellow-brown. The intramedian eye-spots of the forewing and the chain of ocelli on the hindwing more indistinct, narrower, their component parts more isolated. Espiritu Santo, rare.

M. catenarius Perry is the oldest name for the species which is widely distributed in collections under the name of *epistrophis Hbn.*, and which differs from *laertes* in having the row of ocelli on the hindwing rounded instead of elongate, and also placed further apart. In addition most *catenarius* have the distal border of the forewing adorned with isolated black spots, not united into a band, and extending to the anal angle. The ♀♀ are not like the ♂♂, as in *laertes*, but decorated more plentifully with brown spots on the under surface and more distinct submarginal undulate bands on the upper surface. There are some ♀ examples, however, which in the markings approximate to those of the ♂. In Santa Catharina, particularly in the more elevated localities in the neighbourhood of Theresopolis and on the Alto-Uruguay, there occur commonly together with light ♀♀ also examples in which on the underside of the hindwing, especially about the cell and in the submarginal region, the ordinarily separated brown bands are broadly diffused, so as to form grotesque figures and extended undulate bands: = ♀-f. **marmorata** Fruhst. In such examples the black distal bordering

and submarginal spots on the upper surface are also considerably enlarged. Together with ♀♀ with the *nigrescens*. under surface marbled with brown occurs also, though extremely rarely, a black-spotted form (♀-f. **nigrescens form. nov.**), which is before me from the provinces of Paraná to Rio Grande do Sul. *catenarius* inhabits southern Brazil from São Paulo to Santa Catharina. Larva according to Dr. WILHELM MÜLLER on *Inga semialata*; head bright red with hairs of the same colour, body black, red and yellow, with a broad black lateral stripe and a yellow, black-edged mark in the median line. Larva in small companies (20—30). The caterpillars cover some leaves of the food-plant with webs, look like red lumps and are extremely conspicuous. The pupa on the whole resembles that of *Morpho achillides* Fldr. Like *Heliconius besckei catenarius* is one of the characteristic butterflies of Santa Catharina. In contrast to *Morpho anaxibia*, which only occurs in the timber-forests, it frequents rather the underwood, is fond of flying along broad bridle-paths, so far as they run near the rivers, and does not even avoid the neighbourhood of human habitations. Anyone who rides through the country in Santa Catharina from the middle of February to the beginning of April and travels any great distance, will probably observe on calm sunny days as many as 500—800 of these sluggish Morphids floating along as if lost in a dream. In the year 1889 I found it very easy to take 80—100 examples in one day near the orchards and among the tall bamboos on the banks of the Capivary River. Examples which have been on the wing longer also come to spread-out fruit-bait and it is only these which are occasionally observed settled on wet places in the primeval forests on the Alto Uruguay. — In northern Argentina and some districts of Rio *argentinus*. Grande do Sul we meet with a smaller geographical variety: **argentinus** Fruhst. (68 c). On the upper surface of the forewing the distal patches are no longer confluent with the submarginal band, but separate; the black spotting is also appreciably reduced on the upperside of the hindwing and the marbling of the under surface is likewise more delicate. The extreme of the reduction in the markings is found in ♂♂ from Rio Grande *efigurata*. de Sul, which have no black or brown spots at all on the under surface except the median ocelli (= **efigurata form. nov.**) According to MABILDE the larva is extremely gay in colouring and occurs from March to November on various forest trees. 20—30 always inhabit a nest of leaves and fine twigs, which one might take for a wonderful flower, or they sit in a lightly spun web. In November and December they change to the pupae, from which the imagines appear in 20—30 days. The butterflies are then very common from January to March, but become constantly more rare until April, which is already appreciably cool. According to BURMEISTER, who figured the larva of *M. catenarius* and *laertes* in 1878, *catenarius* (*argentinus*) is not rare in Uruguay, very common in the Argentine provinces of Corrientes and Entrerios, and was formerly observed also to the south of the Rio de la Plata and several times even taken at Buenos Ayres.

polyphemus. **M. polyphemus** Dbl. & Hew. (68 c) differs from its Brazilian relatives in the chalky white upper surface of both wings with delicate mother-of-pearl gloss, and also in the projecting apex of the forewing and the sharp teeth of the hindwing. On the upper surface the black distal bordering is absent and the discocellular shows only a quite narrow stripe. The ocelli of the forewing are larger than in *catenarius*, those of the hind- *luna*. wing more distinctly white-centred. As **luna** BUTLER has described an aberration from Mexico with the black spots on both wings unusually well developed. The flight of *polyphemus* is extremely rapid and irregular, and according to GODMAN and SALVIN the species ascends in Guatemala to 4000 ft. and is often met with near the ground in villages or also high up round the tops of trees in the timber-forest. Distributed from Mexico to Guatemala and Nicaragua, occasionally also occurring in Panama.

M. achilles designates a collective species which shows representatives in the whole tropical region of South America. Almost every restricted locality has its own *achilles* form and the races inhabit both the tropical Atlantic and Pacific coasts of the faunistic region. It is very interesting to observe its gradations in colouring, which illustrate very beautifully how the blue colour changes step by step. All the branches are alike characterized by the rounded forewing and a black distal border (variable according to the locality), accompanied by a more or less distinct darkening of the basal half of the wings. The copulatory organs are of the simplest structure. Uncus short, slightly chitinized, point feebly curved, at the ventral side without the swellings so characteristic of *M. achillaena* Hbn. Valve broad, ventrally somewhat flattened, with the usual dorsal pad, near the dorsal end with two distinct teeth, distally with long bristles. Penis characterized by a distinct horn-like tooth, in this contrasting with the *menelaus* group and the species of the subgenus *Iphimedeia*. Larva rather large, cylindrical, of yellowish grey ground-colour, with two irregular brown dorsal stripes, at the sides with confused striation and spotting, on some segments two tufts of red-brown hairs, with shorter hair-pencils at the side and on the fourth and fifth segment. Head densely clothed with stiff hairs and with two short horns at its posterior end. Pupa elongate oval with two short conical horns on the head and of transparent green colour. Larva mostly singly on a *Platymiscium* (SCHATZ). The butterflies keep to damp places in the woods, rise but little above the ground and sometimes drink at wet spots. In Santa Catharina I did not succeed in baiting this species with fruit as can be done, for instance, with *M. catenarius*. The delimitation of the separate races is still quite uncertain; in the first place there is a lack

of material with data and in addition anatomical investigations have yet to be made. The conditions are the most complicated in the Andean region and there seem to be two species there: *achilles* L., which has probably originated from the Amazons, and *achillaena* Hbn., apparently from Central Brazil. We begin here with the branch-races which have a strongly marked black basal area on the upperside of both wings, but indistinct reddish submarginal spots on the hindwing, in contradistinction to *achillaena* Hbn. and the subraces with the basal black indistinct or absent, but with distinct red submarginal spots on the upperside of the hindwing. — **achilles** L. (= *helenor* Cr. ♀), the name-type, came from Surinam and differs from *amazonicus*, *achilles*, which we figure (69 c), chiefly in the somewhat narrower blue median bands on both wings, which are still more reduced in the ♀, particularly on the hindwing. But the ♀ further bears on the forewing a median row of five white dots, beginning at the costal margin and ending in the middle of the median area. Under surface in both sexes with a whitish grey or blue submarginal band, sometimes also dusted with yellowish, on the forewing divided by a black line. Forewing with three, hindwing with four ocelli, which are proximally bordered with grey or greenish white. The larva was figured by Madame MERIAN as long ago as 1705. Ground-colour yellow-grey with probably somewhat darker (red) bands. According to Dr. W. MÜLLER, however, MERIAN's drawings are often fantastic and inaccurate, so that they can only in rare cases be taken seriously. Two well-marked aberrations have already been made known: **leonte** Hew., with hook-shaped *leonte*, prolongation of the proximally bent median band of the hindwing, and **lacrimans** Fruhst., named from CRAMER's figure, with diffused ocelli on the underside of the hindwing, an analagous case to which is found in *Stichophthalma tonkiniana* Fruhst., vol. IX, pl. 103 a. In the Amazon region we meet with *achilles* in different gradations, the blue median bands being still relatively narrow in examples from the lower course, but considerably widened in those from the upper river. — **amazonicus** Fruhst. (69 c). Larger, longitudinal bands *amazonicus*, more brilliant blue, somewhat broader than in *achilles*. White submarginal patches of the forewing more prominent, but the postdiscal white dots either entirely absent or obsolescent. Obidos, flies August to September. **thetis** Btlr. is an aberration from Pará which lacks the ocelli on the under surface of the forewing; *thetis*. **micans** Fruhst. one which is characterized by a bright bronze gloss on the ocelli. — **hector** Rüb. is a further *micans*, *hector*. local form of *achilles*, and according to the example determined for me by Herr RÖBER differs from the type-form in the larger white submarginal punctiform spots of the forewing. The blue median band is somewhat broader, more brilliantly glossy and with green reflection. The black basal area likewise with more intensive blue gloss. The white median bands on the under surface somewhat more prominent, but yet not so well developed as in *pindarus* Fruhst. from Matto Grosso. One ♀ from the upper Rio Negro, East Colombia, taken by FASSL, closely approaches *pindarus* ♀, only differing in the more sharply defined basal area of both wings, with less of the blue reflection, and in the shorter white transcellular band of the forewing, in which it also differs widely from *amazonicus* Fruhst. Of the local form of this species which flies on the upper Rio Negro at 1200 m. FASSL observed 2 ♀♀ ovipositing. The egg is hemispherical, at the base about 1½ mm. in diameter, greenish grey and dully transparent. It has a narrow, red-brown, horizontal ridge about the middle, but is otherwise unmarked and not glossy. — **pindarus** Fruhst. forms the long missing link which connects the Amazon races *pindarus*, with *trojana* Rüb. from Paraguay and *coelestis* Btlr. from Rio Grande do Sul. ♂ above nearest to *amazonicus*, but the black basal area of both wings is already less sharply defined and the ♀ in particular begins to show the dark steel-blue tinge which in *trojana* suffuses both sexes and is still further intensified in *coelestis*, whilst in all the branch-forms of *achilles* it only forms a narrow border to the light blue ornamental band. The costal transcellular white patches of the forewing, as in *amazonicus*, cover two intraneural areas, so that *pindarus* ♂ inclines towards *leontius* Fldr. from Colombia in markings as well as in size. ♀ with distinct red-brown submarginal stripes on the upperside of the hindwing. The under surface tends in the direction of the southern *achilles* races in having the submarginal and median bands almost pure white, only slightly tinged with yellowish. Matto Grosso. — **trojana** Rüb. (71 a) is considered one of the commonest and most characteristic butter- *trojana*. flies of Paraguay, and was first sent to Europe in large numbers about 10 years ago. The ♀, however, seems to be very rare; it strikingly resembles the ♂ in colouring, differing chiefly in the presence of five pure white median punctiform spots on the forewing and in the more intensive violet-blue tinge in the basal area of both wings. Beneath the ♀♀ agree with the ♂♂ in the extended grey-green intraneural areas, which are wanting in the other known *achilles* subspecies. In general *trojana* is more inclined to individual variation than its sister-races; but the maximum of the above-mentioned extension of the foreground of the ocelli on the under surface is reached in **mystica** Fruhst., a form in which on the under surface the whole of the forewing from *mystica*, the white proximal bordering of the ocelli, which is already somewhat tinged with grey-green, to the black-brown admarginal band is powdered with light grey-green. Hindwing: black-brown submarginal band twice as broad as in normal *trojana*. All the rest of the distal area to beyond the ocelli covered with dark moss-green scales. The scales are very dense and form a compact area, which is bent round the ocelli in a sack-shape, completely surrounding the ocelli themselves. — **mullea** Fruhst., on the contrary, designates a mel- *mullea*. notic extreme; ground-colour dark red-brown, above shot with dusky violet. Median band dark blue, very narrowly bordered with blue-violet. Submarginal dots dull rose-coloured, with grey-violet gloss (instead of white). Under surface: all the usually white markings dark grey-green, ocelli ringed with dark ochre-

yellow, very small, on the forewing only one instead of the usual three. According to BURMEISTER *trojana coelestis*, occurs also in the province of Misiones in Argentina. — *coelestis* Btlr. (= *achillides* Fldr.), a well specialized branch-race of southern Brazil, approximates closely to *trojana* Rüb., from which it differs in its smaller size and in having the white submarginal patches of the forewing almost twice as broad, and further in the narrower and lighter, but more glossy blue median band on the upper surface. The red submarginal spots of the hindwing are also more strongly marked and the basal tinge on the upperside of both wings is predominantly steel-blue, with decidedly brighter reflection than in *trojana*. The under surface approaches that of *achillaena* Hbn. in the prominent, very broad white submarginal and median bands. The bronze-green bordering of the ocelli, however, again as in *trojana*. Very local and at the same time rare, not enumerated in any of the local lists of the fauna of Rio Grande do Sul; two ♂♂ only in coll. FRUHSTORFER.

M. achillaena inhabits a smaller area than *achilles*; the species is accordingly also less rich in forms, the local variations confined to narrower limits; the extent of the the colour and markings is shown in our figures pl. 70 a and b. The characters which distinguish it from *achilles* are the absence of a sharply defined black or otherwise considerably darkened basal region on both wings and the more extended transcellular area on the forewing. Structure of the valve analogous to *M. achilles* L. Penis likewise with horny process. Uncus characterized by a very broad ventral swelling, which in *achilles* is absent or scarcely indicated, running out into two pointed processes which are also present in *achilles*. It is worthy of note that the ♀♀ of all the *achillaena* races are commoner than those of the *achilles* forms, with which they otherwise agree bionomically, both sexes remaining near the ground in the woods and never taking lofty, circling flights like the species of the *menelaus*, *cypris* and *rhetenor* groups, or traversing long distances like the members of the *anakeon*, *catenarius* and *polyphemus* series. — *anakeon* Fruhst. has the most northerly distribution of the known races of the west coast. Upper surface near that of *bahiana* (70 b), but the black distal border costally somewhat broader, anally narrower, the white costal spot of the forewing reduced, not encroaching into the transcellular area. Under surface very dark. The median band of the forewing relatively narrow, ocelli ringed with dark yellow like those of *trojana*. Pernambuco, type in coll. STAUDINGER in the Berlin Museum. — *bahiana* Fruhst. (70 b) does not differ materially in the ♂ from the ♀, which we figure, even the white median spots are present, although much reduced. In the ♂♂ also the white spot of the forewing does not extend beyond the subcostal veins and the small size of this patch distinguishes *bahiana* from all the other subspecies of *achillaena*. *bahiana* is also paler beneath than *anakeon* and the more southerly representatives. The rows of ocelli proximally bounded by a nearly always continuous elbowed grey-white median band. Not rare in Bahia and found in company with *Agrias ferdinandi* Fruhst. in the dry, open forests of that province. — *achillaena* Hbn. (= *subfasciata* Rüb. ex Peru, loc. err.) as one of the most easily captured butterflies very commonly finds its way into European collections. *achillaena* flies at Rio de Janeiro and in Espiritu Santo all the year round and prefers shady lowlands. The species does not ascend into the Organ Mountains and is already absent at Petropolis. Larva according to VON BÖNNINGHAUSEN on a prickly climbing-plant; according to BURMEISTER yellow-grey with somewhat darker lateral stripes. ♂ near the figured *achillides* (70 a), but with light blue basal area, the white costal spot of the forewing not materially broader in the ♀. ♀ as a rule much larger than the ♂, the reddish yellow submarginal lunules of the hindwing standing out more distinctly than in *bahiana*. The rows of eye-spots on the under surface surrounded by extended whitish bands. The red anteterminal spots essentially more prominent than in *bahiana*. In the province of Minas Geraes we meet with a transition from the Rio type to the northern race; this has been described as *pellana* Fruhst. ♂. The white costal spot of the forewing only extends to the subcostal and consists in the ♂ of only 2 parts, instead of 3 as in *achillaena*. Black distal border of the forewing narrower, more sharply defined. In the ♀ the white costal spot more extended than in *achillaena*, there are even traces of white patches between the medians. General colouring lighter blue. Under surface: ocelli smaller than in the other *achillaena*, submarginal and ultracellular transverse bands of both wings considerably broader. — *paulista* Fruhst. Distal border of both wings more deeply incised. The white costal spot consists of 4 narrow divisions. Basal area of both wings darker than in *achillaena*, the blue reflection deeper, but even more glossy, with the first traces of the violet tone of *achillides*. The white transverse band on the underside of the forewing strikingly pure white and very extended. Under surface very dark. São Paulo. Concerning the habits Dr. SEITZ writes that the weakness of the body leads to a slow, measured flapping of the wings, producing a gentle, oscillating motion which shows the magnificent gloss of the azure-blue wings to great advantage. — *violaceus* subsp. nov. (70 a) (as *achillides*). Both sexes brilliant dark blue-violet above. The costal white spot is continued in the ♀ between the median veins. Submarginal patches of the forewing much enlarged. Under surface considerably darker than in *achillaena* and as in *paulista* characterized by reddish white anteterminal bands on the hindwing. Bordering of the ocelli on the forewing a peculiar grey-lilac, that of the hindwing pale grey, very much narrower than in the more northerly forms of *achillaena*. *violaceus* scarcely ascends to the higher foothills of the mountains; it is a true lowland species, flies on shady forest-paths and does not come to banana-bait. In the neighbourhood of Blumenau *violaceus* does not seem to be rare; but it has never been recorded as occurring in such abundance as *achilles trojana*. According to Dr. W. MÜLLER the eggs are hemispherical in shape

and break open a round lid on the convex surface when the larvae hatch. This does not take place for several weeks; the larva lives either singly or in small companies of 3—5. Larva on *Platymiscium*, a leguminous plant. Head proportionately very large, high and broad, narrowed above, at the same time rather short with two strong conical processes, horizontally directed posteriorly, placed on a common base. The surface of the head is covered with small pitting, and bears long, black, finely feathered, branched bristles, which give it the appearance of a poodle's head, as with certain *Brassolids*. Larva when first hatched partially transparent, after two days a beautiful chrome-yellow, with broad yellow dorsal and some lateral spots. In the later stages the body becomes extremely variegated, brown, red-yellow, white and black with dark stripes parallel to the margins of the light parts. Pupa rounded, with two short, conical horns, elongate oval, transparent green. This beautiful form has since 1888 passed as *achillides* *Fldr.*, in consequence of STAUDINGER's statements in the „Exotischen Tagfalter“. By comparison with the type, however, I have been able to prove that FELDER's name *achillides* refers to the *M. achilles* race from Rio Grande do Sul, which BUTLER had named *M. coelestis* a year before. The *achillides* of our plate was consequently without a name, and I propose that of *violaceus*, as it is the only *Morpho* yet known with the upper surface blue-violet.

M. patroclus *Fldr.* is a handsome, interesting species of the *achilles* group from eastern Colombia, *patroclus*, near to *papirius* *Hpffr.* from Peru, and apparently occurring only in the lowlands. It was met with by FASSL at Villaviciencia at an elevation of 400 m., whilst on the upper Rio Negro at about 800 m. it is already replaced by the very different *M. achilles hector* *Röb.* In contrast to the round-winged *achilles* type *patroclus* has the wings elongated, the hindwing in particular posteriorly narrowed and long-produced. Base of the upper surface of both wings broadly deep black, with inappreciable dark violet-blue reflection. The ornamental band strikingly broad, but nevertheless leaving a more extended black apical patch than in *papirius*. Anal angle of the hindwing as in *agamedes* and *phokylides* with blue instead of red inner-marginal spot. Under surface differing from all the *achilles* races and also from *papirius* in the very beautiful ochre-yellow bordering of the ocelli, the very broad greenish white median macular band of the forewing and the extended light green foreground of the ocelli on the hindwing. Under surface of the wings in both sexes a peculiar rich brownish ochre or earth-colour with dull green gloss, distinctly perceptible even in FELDER's type, which is over 50 years old and which I have before me through the kindness of the directors of the Tring Museum, and showing up so distinctly in FASSL's example that I doubted whether it was natural. — **theodorus** *Fruhst.*, from the upper Uaupes, *theodorus*, on the other hand is again normally coloured with the band on the upper surface less brightly glossy. Both wings beneath without brownish green tinge, more approaching the *achilles* colouring with reduced greenish white proximal bordering to the chain of ocelli. — **papirius** *Hpffr.* designates a well differentiated local form, almost *papirius*, a species, from Chanchamayo in Peru, which even surpasses *theodorus* in the extent of the light blue ornamental band on the upper surface, so that the black distal border, particularly on the forewing, is reduced to a breadth of a few millimeters, but contains a row of strongly marked, pure white submarginal dots which shine out as if it were set with pearls. — The culmination in size and in brilliance of colour, however, is not found until we reach the sources of the Amazon in Peru. Here the geographical variety, **agamedes** *subsp. agamedes*, *nov.*, attains in the forewing a length of 75 mm. against 55 mm. in *achilles achilles* *L.* from Surinam, and the light blue ornamental band on the upper surface is 30 mm. in breadth, whilst the corresponding band in *achilles* does not exceed 12—13 mm. Hence the distal black border of both wings is naturally much reduced, although the basal deep black area, distally bordered with steel-blue, which is so characteristic of *achilles*, undergoes no reduction. The brilliant median band is only somewhat widened in the cell of the forewing and encroaches even more than in *papirius* *Hpffr.* into the cell of the hindwing. Beneath also an approach to *M. papirius* *Hpffr.* results from the essentially larger ocelli, which have first a light ochre-yellow, then a bronzy light green bordering, which in beauty and extent is hardly excelled by that of *patroclus* *Fldr.* — **phokylides** *phokylides*, *Fruhst.*, from Yungas in Bolivia, recently taken in large numbers, forms the natural continuation of *agamedes*, but shows a decrease in wing-expanse. The median band becomes darker and is narrowed both towards the costal margin of the forewing and the inner angle of the hindwing. The ocelli of the under surface are again dull yellow and washed-out whitish, margined with blue, so causing an approach to *theodorus*. Valve distally sharply dentate, uncus without the ventral lamellae which characterize *achillaena* and *achillaena subfasciata* *Röb.*

M. peleides occurs from Mexico southwards to Ecuador and eastwards in Venezuela. Although it only inhabits a comparatively small area its local variability is unexampled among the *Morphids*, and no other species shows even approximately such sudden mutations within circumscribed localities (not even excepting island races). The races from Mexico, Honduras, Nicaragua and Colombia approximate pretty closely, but between them in Guatemala and Costa Rica we find subspecies in which the usual garb is completely changed (in Guatemala on the underside also) and whose identity is only proved by the wing-contour and the position of the ocelli. Of great interest also is the occurrence of two geographical races in Guatemala, of which one only inhabits the Atlantic slopes of the central volcanos, the other, which is considerably rarer, exclusively

the Pacific coast, so that GODMAN and SALVIN in 1881 still treated them as separate species. In order to explain the present heterogeneous mixture of races these authors advanced the theory that the Isthmus of Panama was originally inhabited by two species of *Morpho*, of which certain forms of *hyacinthus* Btlr. inhabited the islands which occupied the position of the present Panama and Costa Rica, the older species, which they considered to be *peleides* Koll., being only indigenous to Colombia, and further that no *Morpho* at that time occurred in Guatemala and Mexico. But after geological revolutions had produced the present union of the land, *peleides* was enabled to push its way along the isthmus, passing *hyacinthus* in Costa Rica, and occupying the rest of Central America, Yucatan and Southern Mexico. Those forms which were developed on the Pacific coast of Guatemala were most modified and became *octavia*, while the rest only differed slightly from their Colombian ancestors. According to our present knowledge such a complicated explanation is no longer needed; the Morphids in question are simply local and individual variations, such as we meet with, but modified to an even greater degree, among the members of other families (Papilionids, Euthaliids), particularly in Asia. *peleides* is undoubtedly a near relation of *achilles* and probably its northern form, as GODMAN and SALVIN assumed, and in Colombia *peleides* starts where *achilles* disappears, as it only inhabits the western part of the country from Bogotá to the Pacific coast, whilst *achilles* stops before the East Cordilleras. *peleides* agrees with *achilles* in habits, as it also frequents the underwood, unlike its sun-loving congeners *M. cypris* and *theseus*. The individual forms approach *achilles* above in bearing a broad black-brown basal area (*limpida*, 67 a) or approximate more to *achillaena* in the absence of basal darkening (*octavia*, 69 a). Yet between the two main forms all imaginable transitions occur; thus the basal area may also have a light blue or a dark steel-blue reflection as in *peleus* Rüb. Extremely variable also are the submarginal white spots and costal patches of the forewing, of which two or three more or less prominent rows may be present, accompanied by transcellular median white dots, but likewise quite irregular. Only in the ♀♀ is this median ornamentation always present and in them the brown distal border on the forewing is sometimes widened nearly to the cell. The ♀♀ as a rule have the upper surface of the hindwing light glossy blue throughout, but there occur also ♀-forms with almost entirely brown upper surface, on which only the rudiments of a median band, in this case dark blue, are present. The colouring of the under surface also varies, apparently quite without system, the races from Colombia and Mexico being the deepest black-brown beneath, while between them in Central America occur the examples which are strongly banded with whitish in the distal part, especially on the forewing. One character, however, remains constant through all the forms; this is the nose-shaped distal projection of the whitish grey median line on the underside of the hindwing, which forms an acute angle between the anterior and the three posterior ocelli and is never interrupted at this place, whereas in *achillaena* races the median band may be broken up or continuous within the limits of the same geographical race. Clasp-
montezuma. ing organs very close to those of *M. achilles*; valve distally more distinctly dentate, but appreciably more narrowly, the dorsal pad, however, already reduced. Ventral process of the uncus as weak as in *achilles*. Penis
zela. armed with longer and more pointed teeth than in *achilles* and *achillaena*. — **montezuma** Guén. is the most northerly and the smallest race and at the same time the most easily distinguished on account of the rounded forewing, which is surrounded by a relatively broad deep black distal border containing only one row of pure white punctiform spots, of the size of a pin's head. The distal border sends out fine black points along the veins. Under surface predominantly red-brown with strikingly small ocelli and reddish yellow anteterminal bands on both wings and a reddish yellow shade beyond the cell on the forewing; ♀♀ are apparently rare; they are wanting in my collection. GODMAN and SALVIN give Yucatan as locality. — Through the firm of
octavia. BANG-HAAS I recently received an interesting local or seasonal, perhaps mountain form, **zela** *subsp. nov.*, of distinct *montezuma* character in its rounded forewing and with still more pronounced, dull vinous bands on the under surface, and noteworthy above for having the black distal border of the forewing only a few mm. in breadth, very little ornamented with white, and proximally sending out no black teeth along the veins.
zonaras. **octavia**. A more exact locality than Mexico could not be ascertained. — **octavia** Bates (69 a) must be considered one of the most remarkable and most easily recognized Morphids on account of its delicate light blue but uncommonly glossy reflection and the extended whitish brown bordering of the wings. The ♀ is even paler than the ♂ and in both sexes the eye-spots of the under surface show through distinctly. Under surface basally light cocoa-brown, the distal area light havanna-brown with slight violet sheen, whitish bands and flesh-coloured anteterminal spots. Ocelli, particularly those of the hindwing, with very broad light ochre-yellow bordering. Habitat exclusively the forests of the Pacific coast of Guatemala.
 — As **zonaras** *subsp. nov.* we here introduce a further local form allied to the *octavia* type, the type of which is in the British Museum, with the very doubtful locality "Colombia". The ♂ differs from *octavia* in the still purer white anteterminal shade and the lighter blue basal part of both wings. Beneath the brown marginal area extends further proximad to the wall of the cell and the submarginal
